FortiOS™ Handbook

01-602-481047-20180726

TABLE OF CONTENTS

Chapter 1 - What's New for FortiOS 6.0	48
Fortinet Security Fabric	48
Security Fabric automation	48
Security rating	48
Solution and service integration	48
Multi-cloud support (Security Fabric connectors)	50
Manageability	51
Asset tagging	51
FortiSwitch network assisted device detection and destination name resolution	51
Global security profiles	51
Networking	52
SD-WAN improvements	52
Cloud-assisted one-click VPN	53
IPv6 enhancements	53
NAT enhancements	53
EMAC-VLAN support	53
Security	54
FortiGuard virus outbreak prevention	54
FortiGuard content disarm and reconstruction	54
Application groups for NGFW policies	54
Application control rule sequencing	54
Threat Feeds (external dynamic block lists)	55
FortiAP-S bridge mode security profiles	55
Chapter 2 - Getting Started	56
Differences between models	56
What's new in FortiOS 6.0	57
Installation	58
Quick installation using DHCP	58
Installing a FortiGate in NAT/route mode	59
Using a virtual wire pair	61
Using the GUI	63
Connecting to the GUI using a web browser	63
Menus	64
Dashboard	66

Feature Visibility.....	69
Tables.....	70
Text strings.....	72
Using the CLI.....	74
Connecting to the CLI.....	74
Command syntax.....	79
Sub-commands.....	84
Permissions.....	88
Tips.....	89
FortiExplorer for iOS.....	97
Getting started with FortiExplorer.....	97
LED specifications.....	102
Sample FortiGate faceplates.....	102
LED status codes.....	103
About alarm levels.....	104
LED status codes for ports.....	104
Inspection mode.....	106
Basic administration.....	110
Registration.....	110
System Settings.....	110
Passwords.....	114
Firmware.....	116
Configuration backups.....	124
FortiGuard.....	130
FortiCloud.....	138
Troubleshooting your FortiGate installation.....	140
Resources.....	143
Best Practices.....	143
The Fortinet Cookbook.....	143
The Fortinet Video Library.....	143
The FortiOS Handbook.....	143
Fortinet Support.....	143
Chapter 3 - Authentication.....	144
What's new in FortiOS 6.0.1.....	145
What's new in FortiOS 6.0.....	145
Introduction to authentication.....	146
What is authentication?.....	146
Methods of authentication.....	146
Types of authentication.....	148
Single sign-on authentication for users.....	151
User's view of authentication.....	152
FortiGate administrator's view of authentication.....	153

General authentication settings.....	154
Authentication servers.....	155
FortiAuthenticator servers.....	155
RADIUS servers.....	155
LDAP servers.....	163
TACACS+ servers.....	172
POP3 servers.....	174
SSO servers.....	174
RSA ACE (SecurID) servers.....	176
Users and user groups.....	181
Users.....	181
User groups.....	196
Managing guest access.....	202
Configuring guest user access.....	202
Guest access in a retail environment.....	204
Configuring authenticated access.....	208
Authentication timeout.....	208
Password policy.....	209
Authentication protocols.....	211
Authentication in captive portals.....	212
Authentication in security policies.....	212
Authentication replacement messages.....	213
Kerberos authentication for explicit web and transparent web proxy users.....	218
VPN authentication.....	228
Captive portals.....	233
Introduction to captive portals.....	233
Configuring a captive portal.....	233
Customizing captive portal pages.....	235
Certificate-based authentication.....	241
What is a security certificate?.....	241
Certificates overview.....	242
Managing X.509 certificates.....	245
Troubleshooting certificates.....	250
Configuring certificate-based authentication.....	255
Support for per-VDOM certificates.....	257
Example — Generate a CSR on the FortiGate unit.....	258
Example — Generate and Import CA certificate with private key pair on OpenSSL.....	259
Example — Generate an SSL certificate in OpenSSL.....	260
Single sign-on using a FortiAuthenticator unit.....	263
User's view of FortiAuthenticator SSO authentication.....	263
Administrator's view of FortiAuthenticator SSO authentication.....	263
Configuring the FortiAuthenticator unit.....	264

Configuring the FortiGate unit	265
Configuring the FortiClient SSO Mobility Agent	266
Viewing SSO authentication events on the FortiGate unit	266
Single sign-on to Windows AD	268
Introduction to SSO with Windows AD	268
Configuring SSO to Windows AD	268
FortiOS FSSO log messages	273
Testing FSSO	274
Troubleshooting FSSO	274
Agent-based FSSO	276
Introduction to agent-based FSSO	276
FSSO NTLM authentication support	282
Agent installation	285
Configuring the FSSO collector agent for Windows AD	290
Configuring the FSSO TS agent for Citrix	302
Configuring FSSO with Novell networks	303
Configuring FSSO advanced settings	305
Configuring FSSO on FortiGate units	310
FortiOS FSSO log messages	315
Testing FSSO	317
Troubleshooting FSSO	318
SSO using RADIUS accounting records	321
User's view of RADIUS SSO authentication	321
Configuration overview	321
Configuring the RADIUS server	321
Creating the FortiGate RADIUS SSO agent	322
Defining local user groups for RADIUS SSO	324
Creating security policies	325
Example - webfiltering for student and teacher accounts	326
Monitoring authenticated users	329
Monitoring firewall users	329
Monitoring SSL VPN users	329
Monitoring IPsec VPN users	330
Monitoring users quarantine	330
Examples and troubleshooting	332
Firewall authentication example	332
LDAP dial-in using member-attribute example	338
RADIUS SSO example	340
Troubleshooting	348
Chapter 4 - Best Practices	349
Introduction	349
General considerations	349

Customer service and technical support	349
Fortinet Knowledge Base	349
System and performance	350
Performance	350
Shutting down	350
Migration	351
Information gathering	351
Object and policy migration	351
Testing and validation	351
Going live and obtaining feedback	352
Adding new services	352
Environmental specifications	353
Grounding	353
Rack mounting	353
Firmware	355
Firmware change management	355
Performing a firmware upgrade	358
Performing a firmware downgrade	359
Performing a configuration backup	359
Security Profiles (AV, Web Filtering etc.)	362
Firewall	362
Security	362
Authentication	363
Antivirus	363
Antispam	363
Intrusion Prevention System (IPS)	363
Email filter	364
URL filtering	364
Web filtering	365
Patch management	365
Policy configuration	365
Networking	367
Routing configuration	367
Advanced routing	367
Network Address Translation (NAT)	368
Transparent Mode	368
Using virtual IPs (VIPs)	368
FGCP high availability	369
Heartbeat interfaces	369
Interface monitoring (port monitoring)	370
WAN Optimization	371
Virtual Domains (VDOMs)	373

Per-VDOM resource settings	373
Virtual domains in NAT/Route mode	373
Virtual clustering	373
Explicit proxy	374
Wireless	375
Encryption and authentication	375
Geographic location	375
Network planning	375
Lowering the power level to reduce RF interference	376
Wireless client load balancing	376
Local bridging	376
Advertising SSIDs	377
Using static IPs in a CAPWAP configuration	377
Logging and reporting	378
Log management	378
System memory and hard disks	379
Chapter 5 - FortiOS Carrier	380
What's new in FortiOS Carrier 6.0	380
Overview of FortiOS Carrier features	382
Overview	382
MMS	382
GTP	382
MMS Concepts	382
MMS background	382
How FortiOS Carrier processes MMS messages	386
MMS protection profiles	396
Bypassing MMS protection profile filtering based on carrier endpoints	397
Applying MMS protection profiles to MMS traffic	397
MMS Configuration	397
MMS profiles	397
MMS Content Checksum	412
Notification List	413
Message Flood	415
Duplicate Message	417
Carrier Endpoint Filter Lists	418
Message flood protection	421
Duplicate message protection	432
Employing MMS Security features	439
GTP basic concepts	453
PDP Context	454
GPRS security	455
Parts of a GTPv1 network	456

Radio access	457
Transport	457
Billing and records	460
GPRS network common interfaces	461
GTP Configuration	462
Introduction to GTP	462
GTP Profile	464
Configuring GTP on FortiOS Carrier	484
GTP message type filtering	493
GTP identity filtering	500
SCTP Concepts	506
SCTP Firewall	508
Troubleshooting	510
FortiOS Carrier diagnose commands	510
Applying IPS signatures to IP packets within GTP-U tunnels	511
GTP packets are not moving along your network	512
Chapter 6 - Firewall	517
Fundamentals	517
FortiGate firewall components	517
Firewall optimization	518
How does a FortiGate protect your network?	519
What's new for Firewall in 6.0.1	520
What's new for Firewall in 6.0	520
Firewall concepts	522
What is a firewall?	522
FortiGate modes	525
How packets are handled by FortiOS	526
Interfaces and zones	527
Access control lists	528
Firewall policies	529
Policy modes	542
Security profiles	545
NAT	559
IP pools	572
Services and TCP ports	575
VPN policies	601
DSRL	601
Interface policies	602
DoS protection	602
Local-In policies	608
Security policy 0	609
DNS traffic in NGFW policy-mode	610

Deny policies.....	610
Accept policies.....	610
Fixed port.....	610
Endpoint security.....	611
Traffic logging.....	611
IPv6.....	613
IPv6 addressing.....	613
IPv6 packet structure.....	614
Benefits of IPv6.....	614
IPv6 in FortiOS.....	614
IPv6 features.....	615
IPv6 configuration.....	637
Network defense.....	665
Monitoring.....	665
Blocking external probes.....	665
Defending against DoS attacks.....	670
Inside FortiOS: Denial of Service (DoS) protection.....	675
About DoS and DDoS attacks.....	675
FortiOS DoS and DDoS protection.....	675
FortiOS DDoS prevention.....	676
Configuration options.....	677
DoS policies.....	678
Hardware acceleration.....	678
The FortiGuard Center.....	678
Policy configuration.....	679
Viewing firewall policies.....	679
Policy names.....	681
IPv4 policy.....	682
IPv6 policy.....	687
NAT64 policy.....	689
NAT46 policy.....	691
Central SNAT.....	692
IPv4 access control list.....	695
IPv6 access control list.....	696
IPv4 DoS policy.....	697
IPv6 DoS policy.....	702
Multicast policy.....	703
SSL mirroring for policies.....	704
Object configuration.....	705
UUID support.....	705
Addresses.....	705
Virtual IPs.....	728

Configuring IP pools.....	736
Services.....	742
Firewall schedules.....	749
Secure web gateway, WAN optimization, web caching and WCCP.....	756
Before you begin.....	756
FortiGate models that support WAN optimization.....	756
Distributing WAN optimization, explicit proxy, and web caching to multiple CPU cores.....	756
Dispatching traffic to WAD worker based on source affinity.....	756
Toggling disk usage for logging or wan-opt.....	757
Example topologies relevant to WAN optimization.....	759
Basic WAN optimization topology.....	759
Out-of-path WAN optimization topology.....	760
Topology for multiple networks.....	761
WAN optimization with web caching.....	761
Explicit web proxy topologies.....	762
Explicit FTP proxy topologies.....	762
Web caching topologies.....	763
WCCP topologies.....	764
Inside FortiOS: WAN optimization.....	765
Centralize without compromising your WAN performance.....	765
FortiOS WAN optimization.....	765
Protocol optimization.....	765
Web caching.....	766
Byte caching.....	766
Server monitoring and management.....	767
SSL acceleration.....	767
VPN replacement.....	767
Road warriors and home workers.....	767
WAN optimization concepts.....	769
Client/server architecture.....	769
WAN optimization peers.....	770
Protocol optimization.....	770
Protocol optimization and MAPI.....	771
Byte caching.....	771
WAN optimization transparent mode.....	772
Operating modes and VDOMs.....	773
WAN optimization tunnels.....	773
WAN optimization and user and device identity policies, load balancing and traffic shaping.....	774
WAN optimization and HA.....	775
WAN optimization, web caching and memory usage.....	775
WAN optimization configuration.....	776

Manual (peer-to-peer) and active-passive WAN optimization.....	776
WAN optimization profiles.....	778
Monitoring WAN optimization performance.....	781
WAN optimization configuration summary.....	782
WANopt storage.....	785
WANopt cache service.....	786
Video caching.....	787
Best practices.....	789
Example basic manual (peer-to-peer) WAN optimization configuration.....	789
Example active-passive WAN optimization.....	796
Example adding secure tunneling to an active-passive WAN optimization configuration.....	803
Peers and authentication groups.....	811
Basic WAN optimization peer requirements.....	811
How FortiGate units process tunnel requests for peer authentication.....	811
Configuring peers.....	812
Configuring authentication groups.....	813
Secure tunneling.....	815
Monitoring WAN optimization peer performance.....	816
Web cache concepts.....	817
Turning on web caching for HTTP and HTTPS traffic.....	817
Turning on web caching for HTTPS traffic.....	818
Changing the ports on which to look for HTTP and HTTPS traffic to cache.....	820
Web caching and HA.....	821
Web caching and memory usage.....	821
Changing web cache settings.....	821
Web cache configuration.....	825
Forwarding URLs to forwarding servers and exempting web sites from web caching... ..	825
Monitoring web caching performance.....	827
Example web caching of HTTP and HTTPS Internet content for users on an internal network.....	827
Example reverse proxy web caching and SSL offloading for an Internet web server using a static one-to-one virtual IP.....	830
Using a FortiCache as a cache service.....	834
WCCP concepts.....	835
WCCP Cisco to FortiGate client using L2-forwarding tunneling.....	835
WCCP configuration.....	836
WCCP configuration overview.....	836
WCCP service groups, service numbers, service IDs and well known services.....	836
Example caching HTTP sessions on port 80 using WCCP.....	840
Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP.....	842
WCCP packet flow.....	845

Configuring the forward and return methods and adding authentication	845
WCCP messages	846
Troubleshooting WCCP	846
Web proxy concepts	848
Proxy policy	848
Proxy authentication	848
Proxy addresses	852
Web proxy firewall services and service groups	852
Learn client IP	853
Web proxy configuration	855
General web proxy configuration steps	855
Logging options in web proxy profiles	859
Policy matching based on referrer headers and query strings	860
Multiple web proxy PAC files in one VDOM	862
Explicit proxy concepts	864
The FortiGate explicit web proxy	864
Other explicit web proxy options	865
Proxy chaining (web proxy forwarding servers)	867
Security profiles, threat weight, device identification, and the explicit web proxy	870
Explicit web proxy sessions and user limits	871
Explicit proxy configuration	873
Configuring an external IP address for the IPv4 explicit web proxy	873
Configuring an external IP address for the IPv6 explicit web proxy	873
Restricting the IP address of the IPv4 explicit web proxy	873
Restricting the outgoing source IP address of the IPv4 explicit web proxy	873
Restricting the IP address of the explicit IPv6 web proxy	874
Restricting the outgoing source IP address of the IPv6 explicit web proxy	874
Explicit proxy firewall address types	874
Proxy auto-config (PAC) configuration	874
Unknown HTTP version	875
Authentication realm	875
Implementing botnet features	875
Adding disclaimer messages to explicit proxy policies	876
Changing HTTP headers	876
Preventing the explicit web proxy from changing source addresses	877
Kerberos and NTLM authentication	882
Kerberos authentication for explicit proxy users	882
Transparent proxy concepts	892
More about the transparent proxy	892
Transparent proxy configuration	895
FTP proxy concepts	899
The FortiGate explicit FTP proxy	899

How to use the explicit FTP proxy to connect to an FTP server.....	900
Security profiles, threat weight, device identification, and the explicit FTP proxy.....	902
Explicit FTP proxy sessions and user limits.....	902
FTP proxy configuration.....	903
General explicit FTP proxy configuration steps.....	903
Restricting the IP address of the explicit FTP proxy.....	905
Restricting the outgoing source IP address of the explicit FTP proxy.....	905
Example users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning.....	906
Diagnose commands for WAN optimization.....	911
get test {wad wccpd} <test_level>.....	911
diagnose wad.....	912
diagnose wacs.....	916
diagnose wadbd.....	917
diagnose debug application {wad wccpd} [<debug_level>].....	917
diagnose test application wad 2200.....	917
Chapter 7 - FortiView.....	920
What's new in FortiOS 6.0.....	921
What's New in FortiOS 6.0.....	921
Purpose.....	923
Overview.....	924
Enabling FortiView.....	925
FortiView feature support - platform matrix.....	925
Configuration dependencies.....	929
FortiView interface.....	931
FortiView consoles.....	935
Sources.....	936
Destinations.....	936
Applications.....	937
Cloud Applications.....	937
Web Sites.....	938
Threats.....	939
WiFi Clients.....	940
Traffic Shaping.....	940
System Events.....	940
VPN.....	941
Endpoint Vulnerability.....	942
Threat Map.....	942
Policies.....	943
Interfaces.....	944
FortiSandbox.....	944
All Sessions.....	945

Reference.....	946
Filtering options.....	947
Drill-Down Options.....	949
Columns displayed.....	950
Risk level indicators.....	956
Troubleshooting FortiView.....	958
No logging data is displayed.....	958
Logging is enabled, but data is not appearing.....	958
Chapter 8 - Fortinet Communication Ports and Protocols.....	959
What's new in FortiOS 6.0.....	959
Introduction.....	960
FortiGate open ports.....	961
FortiAnalyzer open ports.....	965
FortiAP-S open ports.....	967
FortiAuthenticator open ports.....	969
FortiClient open ports.....	972
FortiClient.....	972
FortiClient EMS.....	974
FortiClient for Chromebook.....	975
FortiClient EMS for Chromebook.....	976
FortiCloud open ports.....	977
FortiDB open ports.....	978
FortiGuard open ports.....	979
FortiMail open ports.....	982
FortiManager open ports.....	987
FortiPortal open ports.....	990
FortiSandbox open ports.....	992
Services and port numbers required for FortiSandbox.....	993
3rd-party servers open ports.....	994
Fortinet proprietary protocols.....	996
FGCP - FortiGate Clustering Protocol.....	997
FGSP - FortiGate Session Life Support Protocol.....	1004
FGFM - FortiGate to FortiManager Protocol.....	1009
SLBC - Session-aware Load Balancing Cluster.....	1012
Fortinet Security Fabric.....	1020
FortiTelemetry/On-Net/FortiClient Endpoint Compliance.....	1022
FortiGuard.....	1025
FortiLink.....	1029
FortiOS WAN optimization.....	1035
FSSO - Fortinet Single Sign-On.....	1039
OFTP - Optimized Fabric Transfer Protocol.....	1043
FortiClient EMS - Enterprise Management Server.....	1044

Chapter 9 - FortiWiFi and FortiAP Configuration Guide	1046
What's new in FortiOS 6.0.1	1046
What's new in FortiOS 6.0	1047
Introduction to wireless networking	1048
Wireless concepts	1048
Security	1049
Authentication	1051
Wireless networking equipment	1051
Automatic Radio Resource Provisioning	1052
Captive portals	1054
Introduction to captive portals	1054
Configuring a captive portal	1054
Customizing captive portal pages	1057
Configuration example - captive portal WiFi access control	1062
Configuring a WiFi LAN	1065
Overview of WiFi controller configuration	1065
Setting your geographic location	1067
Creating a FortiAP profile	1068
Defining a wireless network interface (SSID)	1070
Defining SSID groups	1079
Dynamic user VLAN assignment	1080
Configuring user authentication	1083
Configuring firewall policies for the SSID	1085
Configuring the built-in access point on a FortiWiFi unit	1087
Enforcing UTM policies on a local bridge SSID for managed smart APs	1087
Access point deployment	1089
Overview	1089
Network topology for managed APs	1089
Discovering and authorizing APs	1093
Advanced WiFi controller discovery	1099
Wireless client load balancing for high-density deployments	1101
FortiAP groups	1103
LAN port options	1103
Preventing IP fragmentation of packets in CAPWAP tunnels	1106
LED options	1107
CAPWAP bandwidth formula	1108
Wireless mesh	1110
Overview of wireless mesh	1110
Configuring a meshed WiFi network	1113
Configuring a point-to-point bridge	1116
Hotspot 2.0	1118
Combining WiFi and wired networks with a software switch	1122

Combining WiFi and wired networks with a software switch	1122
FortiAP local bridging (Private cloud-managed AP)	1124
Using bridged FortiAPs to increase scalability	1126
Using remote WLAN FortiAPs	1128
Configuring the FortiGate for remote FortiAPs	1128
Configuring the FortiAP units	1129
Preauthorizing FortiAP units	1130
Features for high-density deployments	1131
Multiple FortiAP firmware upgrades at once	1131
Power save feature	1131
Broadcast packet suppression	1132
Multicast to unicast conversion	1133
Ignore weak or distant clients	1133
Turn off the 802.11b protocol	1133
Disable low data rates	1134
Limit power	1134
Use frequency band load-balancing	1134
AP load balancing	1135
Application rate-limiting	1136
AP group management and dynamic VLAN assignment	1136
Sharing tunnel SSIDs within a single managed AP between VDOMs as a virtual AP for multi-tenancy	1136
Manual quarantine of devices on FortiAP (tunnel mode)	1136
Locate a FortiAP with LED blinking	1138
Wireless controller optimization for large deployment - AP image upgrade	1138
Control message off-loading and aeroscout enhancement	1139
Protecting the WiFi network	1140
Wireless IDS	1140
WiFi data channel encryption	1141
Protected Management Frames and Opportunistic Key Caching support	1142
Bluetooth Low Energy (BLE) Scan	1142
Preventing local bridge traffic from reaching the LAN	1143
FortiAP-S bridge mode security profiles	1144
DHCP snooping and option 82 (circuit-id) options for wireless access points	1144
Wireless network monitoring	1145
Monitoring wireless clients	1145
Monitoring rogue APs	1145
Suppressing rogue APs	1150
Monitoring wireless network health	1150
Configuring wireless network clients	1152
Windows XP client	1152
Windows 7 client	1157

Mac OS client	1161
Linux client	1163
Troubleshooting	1165
Wireless network examples	1168
Basic wireless network	1168
A more complex example	1173
Managing a FortiAP with FortiCloud	1183
FortiCloud-managed FortiAP WiFi	1183
FortiCloud-managed FortiAP WiFi without a key	1184
Using a FortiWiFi unit as a client	1186
Use of client mode	1186
Configuring client mode	1188
Support for location-based services	1190
Overview	1190
Configuring location tracking	1190
Viewing device location data on the FortiGate unit	1191
Troubleshooting	1193
FortiAP shell command through CAPWAP control tunnel	1193
Signal strength issues	1193
Throughput issues	1197
Connection issues	1198
General problems	1203
Packet sniffer	1206
Useful debugging commands	1210
Reference	1212
FortiAP web-based manager	1213
Wireless radio channels	1215
WiFi event types	1217
FortiAP CLI	1217
Chapter 10 - Hardening your FortiGate	1224
Building security into FortiOS	1225
Boot PROM and BIOS security	1225
FortiOS kernel and user processes	1225
Administration access security	1225
Network security	1227
FIPS and Common Criteria	1228
PSIRT advisories	1228
FortiOS ports and protocols	1229
FortiOS open ports	1229
Closing open ports	1229
Security best practices	1230
Install the FortiGate unit in a physically secure location	1230

Register your product with Fortinet Support	1230
Keep your FortiOS firmware up to date.....	1230
System administrator best practices.....	1230
Global commands for stronger and more secure encryption.....	1234
Disable sending malware statistics to FortiGuard.....	1235
Disable sending Security Rating statistics to FortiGuard.....	1235
Disable auto USB installation.....	1235
Set system time by synchronizing with an NTP server.....	1236
Disable the maintainer admin account.....	1236
Enable password policies.....	1236
Configure auditing and logging.....	1236
Disable unused interfaces.....	1237
Disable unused protocols on interfaces.....	1237
Use local-in policies to close open ports or restrict access.....	1238
Chapter 11 - Hardware Acceleration.....	1240
What's new in FortiOS 6.0.2.....	1240
What's new in FortiOS 6.0.....	1240
Hardware acceleration overview.....	1241
Content processors (CP4, CP5, CP6, CP8, and CP9).....	1241
Security processors (SPs).....	1244
Network processors (NP1, NP2, NP3, NP4, NP4Lite, NP6 and NP6Lite).....	1246
Enabling strict protocol header checking disables all hardware acceleration.....	1250
sFlow and NetFlow and hardware acceleration.....	1250
Checking that traffic is offloaded by NP processors.....	1250
Dedicated management CPU.....	1252
Offloading flow-based content inspection with NTurbo and IPSA.....	1253
Preventing packet ordering problems with NP4, NP6 and NP6lite FortiGates under heavy load.....	1254
NP6 and NP6lite acceleration.....	1255
NP6 session fast path requirements.....	1256
NP6Lite processors.....	1257
NP6 and NP6Lite processors and sFlow and NetFlow.....	1257
NP6 processors and traffic shaping.....	1257
NP Direct.....	1258
Viewing your FortiGate NP6 processor configuration.....	1258
Disabling NP6 and NP6lite hardware acceleration (fastpath).....	1259
Optimizing NP6 performance by distributing traffic to XAUI links.....	1259
Enabling bandwidth control between the ISF and NP6 XAUI ports.....	1261
Increasing NP6 offloading capacity using link aggregation groups (LAGs).....	1261
Configuring inter-VDOM link acceleration with NP6 processors.....	1262
Disabling offloading IPsec Diffie-Hellman key exchange.....	1265
Configuring individual NP6 processors.....	1265

Enabling per-session accounting for offloaded NP6 and NP6lite sessions	1271
Configuring NP6 session timeouts	1272
Configure the number of IPsec engines NP6 processors use	1272
Stripping clear text padding and IPsec session ESP padding	1273
Disable NP6 CAPWAP offloading	1273
Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces	1273
Offloading RDP traffic	1274
NP6 session drift	1274
Optimizing FortiGate-3960E and 3980E IPsec VPN performance	1275
Recalculating packet checksums if the iph.reserved bit is set to 0	1275
FortiGate NP6 architectures	1276
FortiGate-300D fast path architecture	1276
FortiGate-300E and 301E fast path architecture	1276
FortiGate-400D fast path architecture	1278
FortiGate-500D fast path architecture	1279
FortiGate-500E and 501E fast path architecture	1279
FortiGate-600D fast path architecture	1280
FortiGate-800D fast path architecture	1281
FortiGate-900D fast path architecture	1283
FortiGate-1000D fast path architecture	1285
FortiGate-1200D fast path architecture	1287
FortiGate-1500D fast path architecture	1290
FortiGate-1500DT fast path architecture	1291
FortiGate-2000E fast path architecture	1293
FortiGate-2500E fast path architecture	1295
FortiGate-3000D fast path architecture	1298
FortiGate-3100D fast path architecture	1299
FortiGate-3200D fast path architecture	1300
FortiGate-3700D fast path architecture	1303
FortiGate-3700DX fast path architecture	1307
FortiGate-3800D fast path architecture	1311
FortiGate-3810D fast path architecture	1313
FortiGate-3815D fast path architecture	1314
FortiGate-3960E fast path architecture	1316
FortiGate-3980E fast path architecture	1317
FortiGate-5001D fast path architecture	1319
FortiGate-5001E and 5001E1 fast path architecture	1321
FortiController-5902D fast path architecture	1323
FortiGate NP6lite architectures	1326
FortiGate-200E and 201E fast path architecture	1326
NP4 and NP4Lite acceleration	1328

Viewing your FortiGate NP4 processor configuration.....	1328
NP4 and NP4Lite processors and sFlow and NetFlow.....	1329
Configuring NP4 traffic offloading.....	1329
Disabling NP4 and NP4lite hardware acceleration (fastpath).....	1331
Increasing NP4 offloading capacity using link aggregation groups (LAGs).....	1331
NP4 traffic shaping offloading.....	1331
NP4 IPsec VPN offloading.....	1332
Configuring inter-VDOM link acceleration with NP4 processors.....	1332
Offloading NP4 anomaly detection.....	1336
FortiGate NP4 architectures.....	1339
FortiGate-600C.....	1339
FortiGate-800C.....	1340
FortiGate-1000C.....	1341
FortiGate-1240B.....	1342
FortiGate-3040B.....	1343
FortiGate-3140B.....	1344
FortiGate-3140B — load balance mode.....	1345
FortiGate-3240C.....	1345
FortiGate-3600C.....	1347
FortiGate-3950B and FortiGate-3951B.....	1348
FortiGate-3950B and FortiGate-3951B — load balance mode.....	1350
FortiGate-5001C.....	1351
FortiGate-5001B.....	1352
Setting switch-mode mapping on the ADM-XD4.....	1353
Hardware acceleration get and diagnose commands.....	1354
get hardware npu np6.....	1354
diagnose npu np6.....	1354
Using diagnose npu np6 npu-feature to verify enabled NP6 features.....	1355
Using the diagnose sys session/session6 list command.....	1356
diagnose npu np6 session-stats <np6-id> (number of NP6 IPv4 and IPv6 sessions).....	1359
diagnose npu np6 ipsec-stats (NP6 IPsec statistics).....	1361
diagnose sys mcast-session/session6 list (IPv4 and IPv6 multicast sessions).....	1362
diagnose npu np6 sse-stats <np6-id> (number of NP6 sessions and dropped sessions).....	1363
diagnose npu np6 dce <np6-id> (number of dropped NP6 packets).....	1363
diagnose hardware deviceinfo nic <interface-name> (number of packets dropped by an interface).....	1364
diagnose npu np6 synproxy-stats (NP6 SYN-proxied sessions and unacknowledged SYNs).....	1365
Chapter 12 - High Availability.....	1366
What's new in FortiOS 6.0.....	1366
Solving the high availability problem.....	1367

FortiGate Cluster Protocol (FGCP).....	1367
FortiGate Session Life Support Protocol (FGSP).....	1368
VRRP high availability.....	1369
Session-Aware Load Balancing Clustering (SLBC).....	1370
Enhanced Load Balancing Clustering (ELBC).....	1371
Content clustering.....	1371
An introduction to the FGCP.....	1373
About the FGCP.....	1373
Synchronizing the configuration (and settings that are not synchronized).....	1376
Preparing the FortiGates before setting up an FGCP cluster.....	1377
Configuring FortiGates for FGCP HA operation.....	1378
Active-passive and active-active HA.....	1382
Identifying the cluster and cluster units.....	1383
Device failover, link failover, and session failover.....	1384
Primary unit selection.....	1385
HA override.....	1393
FortiGate HA compatibility with DHCP and PPPoE.....	1397
HA and distributed clustering.....	1398
Clusters of three or four FortiGates.....	1399
Disk storage configuration and HA.....	1402
FGCP high availability best practices.....	1403
FGCP HA terminology.....	1405
FGCP support for OCVPN.....	1408
HA GUI options.....	1409
FGCP configuration examples and troubleshooting.....	1412
About the examples in this chapter.....	1412
How to set up FGCP clustering (recommended steps).....	1412
Adding a third FortiGate to an operating cluster and switching to active-active HA.....	1412
Active-active HA cluster in transparent mode.....	1412
FortiGate-5000 active-active HA cluster with FortiClient licenses.....	1424
Replacing a failed cluster unit.....	1434
FGCP HA with 802.3ad aggregated interfaces.....	1436
Example HA and redundant interfaces.....	1447
Troubleshooting HA clusters.....	1458
Virtual clusters.....	1463
Virtual clustering overview.....	1463
Configuring virtual clustering.....	1465
Virtual clustering configuration examples.....	1469
Inter-VDOM links in a virtual clustering configuration.....	1470
Troubleshooting virtual clustering.....	1472
Full mesh HA.....	1473
Full mesh HA overview.....	1473

Example full mesh HA configuration.....	1475
Troubleshooting full mesh HA.....	1485
Operating clusters and virtual clusters.....	1487
Operating a cluster.....	1487
Operating a virtual cluster.....	1487
Managing individual cluster units using a reserved out-of-band management interface.....	1488
Managing individual cluster units using an in-band management IP address.....	1494
Managing individual cluster units in a virtual cluster.....	1494
Shutting down or rebooting the primary unit.....	1495
The primary unit acts as a router for subordinate unit management traffic.....	1495
Cluster communication with RADIUS and LDAP servers.....	1496
Clusters and FortiGuard services.....	1496
Clusters and logging.....	1497
Clusters and SNMP.....	1500
Adding FortiClient licenses to a cluster.....	1503
Cluster members list.....	1505
Virtual cluster members list.....	1505
Viewing HA statistics.....	1506
Changing the HA configuration of an operating cluster.....	1506
Changing the HA configuration of an operating virtual cluster.....	1506
Changing the subordinate unit host name and device priority.....	1507
Upgrading cluster firmware.....	1507
Downgrading cluster firmware.....	1509
Backing up and restoring the cluster configuration.....	1510
Monitoring cluster units for failover.....	1510
Viewing cluster status from the CLI.....	1511
Managing individual cluster units.....	1518
Disconnecting a cluster unit from a cluster.....	1518
Adding a disconnected FortiGate back to its cluster.....	1519
diagnose sys ha dump-by command.....	1520
HA and failover protection.....	1521
About active-passive failover.....	1521
About active-active failover.....	1522
Device failover.....	1522
HA heartbeat and communication between cluster units.....	1523
Cluster virtual MAC addresses.....	1530
Synchronizing the configuration.....	1537
Synchronizing kernel routing tables.....	1546
Configuring graceful restart for dynamic routing failover.....	1547
Link failover (port monitoring or interface monitoring).....	1549
Monitoring VLAN interfaces.....	1555

Sub-second failover.....	1555
Remote link failover.....	1556
Failover and attached network equipment.....	1561
Monitoring cluster units for failover.....	1561
NAT/Route mode active-passive cluster packet flow.....	1561
Transparent mode active-passive cluster packet flow.....	1563
Failover performance.....	1566
Session failover (session-pickup).....	1568
Enabling session-pickup for TCP, UDP, ICMP, and multicast session failover.....	1568
If session pickup is disabled.....	1569
Improving session synchronization performance.....	1569
Session failover limitations for sessions passing through the cluster.....	1570
Session failover limitations for sessions terminated by the cluster.....	1573
Synchronizing IPsec VPN SAs.....	1575
WAN optimization and HA.....	1576
HA and load balancing.....	1577
Load balancing overview.....	1577
Selecting a load balancing schedule.....	1579
Load balancing TCP and UDP sessions.....	1580
Using NP4 or NP6 processors to offload load balancing.....	1580
Configuring weighted-round-robin weights.....	1580
Dynamically optimizing weighted load balancing according to how busy cluster units are.....	1581
Example weighted load balancing configuration.....	1583
NAT/Route mode active-active cluster packet flow.....	1585
Transparent mode active-active cluster packet flow.....	1588
HA with FortiGate-VM and third-party products.....	1592
FortiGate-VM for VMware HA configuration.....	1592
FortiGate-VM for Hyper-V HA configuration.....	1592
Troubleshooting layer-2 switches.....	1593
Failover issues with layer-3 switches.....	1593
Failover and attached network equipment.....	1593
Ethertype conflicts with third-party switches.....	1594
LACP, 802.3ad aggregation and third-party switches.....	1594
VRRP high availability.....	1595
Configuring VRRP.....	1596
Adding an IPv4 VRRP virtual router to a FortiGate interface.....	1596
Adding an IPv6 VRRP virtual router to a FortiGate interface.....	1597
Setting up VRRP failover.....	1597
Using VRRP virtual MAC addresses.....	1599
Setting up VRRP groups.....	1600
Example IPv4 VRRP configuration: two FortiGates in a VRRP group.....	1601

Example IPv4 VRRP configuration: VRRP load balancing two FortiGates and two VRRP groups.....	1603
Optional VRRP configuration settings.....	1604
FortiController-5000 SLBC support.....	1604
FortiGate Session Life Support Protocol (FGSP).....	1606
Session synchronization between FGCP clusters.....	1608
Configuring FGSP HA cluster-sync instances.....	1609
Synchronizing TCP and SCTP sessions.....	1611
Synchronizing the configuration.....	1611
FGSP and firmware upgrades.....	1612
Backing up and restoring the configuration of an FGSP cluster.....	1613
IPsec tunnel synchronization.....	1613
Synchronizing UDP and ICMP (connectionless) sessions.....	1613
Synchronizing NAT sessions.....	1613
Synchronizing asymmetric sessions.....	1614
Synchronizing expectation sessions.....	1615
GTP session synchronization: FGSP for FortiOS Carrier.....	1615
Security profile flow-based inspection and asymmetric traffic.....	1615
Notes and limitations.....	1616
Configuring session synchronization links.....	1616
Basic example configuration.....	1617
Verifying the FGSP configuration and synchronization.....	1619
Chapter 13 - IPsec VPN.....	1621
Introduction.....	1621
What's new in FortiOS 6.0.2.....	1622
What's new in FortiOS 6.0.1.....	1622
What's new in FortiOS 6.0.....	1622
IPsec VPN concepts.....	1624
VPN tunnels.....	1624
VPN gateways.....	1626
Clients, servers, and peers.....	1628
Encryption.....	1629
Authentication.....	1631
Phase 1 and Phase 2 settings.....	1632
Security Association.....	1633
IKE and IPsec packet processing.....	1633
IPsec VPN overview.....	1638
Types of VPNs.....	1638
Planning your VPN.....	1639
General preparation steps.....	1641
How to use this guide to configure an IPsec VPN.....	1641
IPsec VPN in the web-based manager.....	1642

Phase 1 configuration.....	1642
Phase 2 configuration.....	1649
Concentrator.....	1653
IPsec Monitor.....	1654
Phase 1 parameters.....	1655
Overview.....	1655
Defining the tunnel ends.....	1655
Choosing Main mode or Aggressive mode.....	1656
Choosing the IKE version.....	1656
Authenticating the FortiGate unit.....	1658
Authenticating remote peers and clients.....	1660
Defining IKE negotiation parameters.....	1666
Using XAuth authentication.....	1672
Dynamic IPsec route control.....	1673
Phase 2 parameters.....	1675
Phase 2 settings.....	1675
Configuring the Phase 2 parameters.....	1677
Defining VPN security policies.....	1681
Defining policy addresses.....	1681
Defining security policies for policy-based and route-based VPNs.....	1682
Gateway-to-gateway.....	1687
Configuration overview.....	1687
Gateway-to-gateway configuration.....	1689
How to work with overlapping subnets.....	1694
Testing.....	1699
Hub-and-spoke configurations.....	1702
Configuration overview.....	1702
Configure the hub.....	1704
Configure the spokes.....	1709
Dynamic spokes configuration example.....	1712
One-Click VPN (OCVPN).....	1719
General configuration.....	1719
Key exchange.....	1720
Device polling and controller information.....	1720
System states.....	1721
Debugging and logging.....	1721
Dynamic DNS configuration.....	1723
Dynamic DNS over VPN concepts.....	1723
DDNS topology.....	1725
Configuration overview.....	1726
FortiClient dialup-client configuration.....	1736
Configuration overview.....	1736

FortiGate dialup-client configurations	1745
Configuration overview	1745
Supporting IKE Mode Config clients	1753
IKE Mode Config overview	1753
Automatic configuration overview	1753
IKE Mode Config method	1753
Internet-browsing configuration	1759
Configuration overview	1759
Routing all remote traffic through the VPN tunnel	1761
Redundant VPN configurations	1763
Configuration overview	1763
IPsec VPN tunnel aggregate interfaces	1767
Transparent mode VPNs	1769
Configuration overview	1769
IPv6 IPsec VPNs	1774
Configuration examples	1775
L2TP and IPsec (Microsoft VPN)	1786
Overview	1786
Assumptions	1787
Configuration overview	1787
GRE over IPsec (Cisco VPN)	1795
Configuration overview	1796
Configuring the Cisco router	1801
Keep-alive support for GRE	1802
Protecting OSPF with IPsec	1803
Configuration overview	1803
Redundant OSPF routing over IPsec	1810
OSPF over dynamic IPsec	1814
BGP over dynamic IPsec	1817
IPsec Auto-Discovery VPN (ADVPN)	1821
Example ADVPN configuration	1822
Logging and monitoring	1827
Monitoring VPN connections	1827
VPN event logs	1828
Troubleshooting	1829
Common IPsec VPN problems	1829
Troubleshooting connection issues	1833
General troubleshooting tips	1837
Troubleshooting L2TP and IPsec	1838
Troubleshooting GRE over IPsec	1841
Chapter 14 - Logging and Reporting	1844
What's new in FortiOS 6.0	1845

Automatic synchronization of log display location.....	1845
Improved log messages for SD-WAN link quality changes.....	1845
Extended UTM logging and improved syslog configuration.....	1845
Updated reliable syslog encryption to comply with RFC 5425.....	1845
Improved log display consistency at high load.....	1846
Logging and reporting overview.....	1847
What is logging?.....	1847
FortiOS features available for logging.....	1848
Log messages.....	1853
Log files and types.....	1859
Log database and datasets.....	1860
Log devices.....	1862
Reports.....	1866
Best practices: Log management.....	1867
Logging and reporting for small networks.....	1869
Modifying default log device settings.....	1869
Configuring the backup solution.....	1871
Logging and reporting for large networks.....	1873
Modifying default log device settings.....	1873
Configuring the backup solution.....	1875
Advanced logging.....	1878
Log backup and restore tools.....	1878
Configuring logging to multiple Syslog servers.....	1878
Using Automatic Discovery to connect to a FortiAnalyzer unit.....	1879
Activating a FortiCloud account for logging purposes.....	1880
Viewing log storage space.....	1880
Customizing and filtering log messages.....	1881
Viewing logs from the CLI.....	1881
Configuring NAC Quarantine logging.....	1882
Logging local-in policies.....	1882
Tracking specific search phrases in reports.....	1884
Interpreting and configuring FSSO syslog log messages.....	1885
Troubleshooting and logging.....	1887
Using log messages to help in troubleshooting issues.....	1887
Connection issues between FortiGate unit and logging devices.....	1888
Log database issues.....	1888
Logging daemon (Miglogd).....	1890
Chapter 15 - Managing Devices.....	1891
What's new in FortiOS 6.0.....	1891
Managing “bring your own device”.....	1892
Device monitoring.....	1892
Device groups.....	1894

Controlling access with a MAC Address Access Control List	1894
Security policies for devices	1896
Chapter 16 - FortiSwitch Devices Managed by FortiOS 6.0.1	1900
Introduction	1900
Supported models	1900
Support of FortiLink features	1902
Before you begin	1903
How this guide is organized	1903
What's new in FortiOS 6.0.1	1904
What's new in FortiOS 6.0	1904
FortiOS 6.0.1	1904
FortiOS 6.0	1907
Connecting FortiLink ports	1919
1. Enable the switch controller on the FortiGate unit	1919
2. Connect the FortiSwitch unit and FortiGate unit	1919
FortiLink configuration using the FortiGate GUI	1921
Summary of the procedure	1921
FortiLink split interface	1922
Authorizing the FortiSwitch unit	1922
Adding preauthorized FortiSwitch units	1922
Managed FortiSwitch display	1923
Edit a managed FortiSwitch unit	1923
Network interface display	1924
Add link aggregation groups (Trunks)	1924
Configure DHCP blocking, IGMP snooping, STP, and loop guard on managed FortiSwitch ports	1924
FortiLink configuration using the FortiGate CLI	1926
Summary of the procedure	1926
Configure FortiLink on a physical port	1926
Configure FortiLink on a logical interface	1927
Enable multiple FortiLink interfaces	1928
FortiLink mode over a layer-3 network	1928
Network topologies for managed FortiSwitch units	1930
Supported topologies	1930
Single FortiGate managing a single FortiSwitch unit	1931
Single FortiGate unit managing a stack of several FortiSwitch units	1932
HA-mode FortiGate units managing a single FortiSwitch unit	1933
HA-mode FortiGate units managing a stack of several FortiSwitch units	1934
HA-mode FortiGate units managing a FortiSwitch two-tier topology	1935
Single FortiGate unit managing multiple FortiSwitch units (using a hardware or software switch interface)	1936
HA-mode FortiGate units managing two-tier FortiSwitch units with access rings	1937

Dual-homed servers connected to FortiLink tier-1 FortiSwitch units using an MCLAG	1938
Standalone FortiGate unit with dual-homed FortiSwitch access	1939
HA-mode FortiGate units with dual-homed FortiSwitch access	1940
Multi-tiered MCLAG with HA-mode FortiGate units	1941
Grouping FortiSwitch units	1946
Transitioning from a FortiLink split interface to a FortiLink MCLAG	1950
Optional setup tasks	1952
Configuring the FortiSwitch management port	1952
Converting to FortiSwitch standalone mode	1953
Changing the admin password on the FortiGate for all managed FortiSwitch units	1953
Enabling network-assisted device detection	1954
Limiting the number of parallel process for FortiSwitch configuration	1954
FortiSwitch features configuration	1954
Configure VLANs	1955
Configure IGMP settings	1958
Configure LLDP-MED	1958
Configure the MAC sync interval	1960
Configure STP settings	1960
Quarantines	1961
FortiSwitch port features	1966
FortiSwitch ports display	1966
Configuring ports using the GUI	1967
Configuring ports using the FortiGate CLI	1967
FortiSwitch port security policy	1981
Configure the 802.1X settings for a virtual domain	1982
Override the virtual domain settings	1983
Define an 802.1X security policy	1983
Apply an 802.1X security policy to a FortiSwitch port	1985
Test 802.1x authentication with monitor mode	1985
Restrict the type of frames allowed through IEEE 802.1Q ports	1986
RADIUS accounting support	1986
Additional capabilities	1987
Execute custom FortiSwitch commands	1987
View and upgrade the FortiSwitch firmware version	1988
FortiSwitch log export	1989
FortiSwitch per-port device visibility	1989
FortiGate CLI support for FortiSwitch features (on non-FortiLink ports)	1989
Synchronizing the FortiGate unit with the managed FortiSwitch units	1994
Replacing a managed FortiSwitch unit	1995
Troubleshooting	1996
Troubleshooting FortiLink issues	1996
Chapter 17 - Networking	1998

Introduction.....	1998
What's new in FortiOS 6.0.....	1998
Interfaces.....	1999
Administrative access.....	1999
Aggregate interfaces.....	2000
DHCP addressing mode on an interface.....	2001
DHCP servers and relays.....	2002
Interface MTU packet size.....	2010
Interface settings.....	2011
Loopback interfaces.....	2016
One-armed sniffer.....	2017
Physical ports.....	2020
PPPoE addressing mode on an interface.....	2021
Probing interfaces.....	2023
Redundant interfaces.....	2024
Dual Internet connections.....	2025
Secondary IP addresses to an interface.....	2028
Software switch.....	2028
Soft switch example.....	2029
Virtual switch.....	2030
Zones.....	2033
Virtual domains.....	2034
Wireless.....	2035
VLANs.....	2035
Enhanced MAC VLANs.....	2049
Virtual wire pairs.....	2052
Botnet and command-and-control protection.....	2053
DNS.....	2055
DNS settings.....	2055
Additional DNS CLI configuration.....	2055
DDNS.....	2056
DNS servers.....	2057
Advanced static routing.....	2062
Routing concepts.....	2062
Static routing tips.....	2078
Policy routing.....	2078
Static routing in transparent mode.....	2083
Static routing example.....	2084
Dynamic routing.....	2093
Overview.....	2093
Comparison of dynamic routing protocols.....	2096
Choosing a routing protocol.....	2101

Dynamic routing terminology.....	2102
Controlling how routing changes affect active sessions.....	2108
IPv6 in dynamic routing.....	2109
RIP.....	2110
OSPF.....	2146
BGP.....	2187
IS-IS.....	2224
Multicast forwarding.....	2241
Sparse mode.....	2241
Dense mode.....	2242
PIM support.....	2243
Multicast forwarding and FortiGate devices.....	2244
Configuring FortiGate multicast forwarding.....	2245
Multicast routing examples.....	2248
SD-WAN.....	2273
Application control settings in SD-WAN rules.....	2273
Internet services in SD-WAN rules.....	2273
Bandwidth and custom profile options in SD-WAN rules.....	2274
SLA management.....	2275
Multiple server support for health checks.....	2276
IPv6 support for SD-WAN.....	2277
DSCP tagging of forwarded packets in SD-WAN rules.....	2278
SD-WAN and dynamic routing.....	2278
Link priority in SD-WAN rules.....	2279
SD-WAN rule for address negation.....	2279
SD-WAN CLI changes.....	2280
Troubleshooting.....	2281
Netflow support.....	2281
sFlow support.....	2281
Packet capture.....	2283
Chapter 18 - Parallel Path Processing (Life of a Packet).....	2284
Parallel Path Processing.....	2285
High-level list of processes that affect packets.....	2286
Packet flow ingress and egress: FortiGates without network processor offloading.....	2287
Ingress.....	2287
Admission control.....	2288
Kernel.....	2288
UTM/NGFW.....	2290
Content processors (CP8 and CP9).....	2290
Kernel.....	2292
Egress.....	2292
Packet flow: FortiGates with NP6 processors first packet of a new session.....	2293

Network processors (NP6).....	2294
Packet flow: FortiGates with NP6 processors - packets in an offloaded session.....	2295
Packet flow: FortiGates with NP6 processors - packets in an NTurbo session.....	2296
UTM/NGFW packet flow: flow-based inspection.....	2298
UTM/NGFW packet flow: proxy-based inspection.....	2300
UTM/NGFW packet flow: explicit web proxy.....	2302
Comparison of inspection types.....	2304
Mapping security functions to inspection types.....	2304
More information about inspection methods.....	2304
Chapter 19 - Sandbox Inspection.....	2306
An Overview of Sandbox Inspection.....	2307
What is Sandbox Inspection?.....	2307
FortiSandbox Appliance vs FortiSandbox Cloud.....	2307
Sending Files for Sandbox Inspection.....	2308
Using FortiSandbox with a FortiGate.....	2309
Connecting a FortiGate to FortiSandbox.....	2309
FortiSandbox Console.....	2310
Sandbox Integration.....	2311
Overview.....	2311
Example Configuration.....	2312
Sandbox Inspection FAQ.....	2315
Chapter 20 - Fortinet Security Fabric.....	2316
Introduction.....	2316
What's new in FortiOS 6.0.2.....	2316
What's new in FortiOS 6.0.1.....	2316
What's new in FortiOS 6.0.0.....	2317
Fortinet Security Fabric overview.....	2318
Access security.....	2319
Client security.....	2319
Application security.....	2319
Cloud security.....	2319
NOC and SOC security.....	2320
Advanced threat intelligence.....	2320
Partner API.....	2320
The Security Fabric solution components.....	2321
Devices in the Security Fabric.....	2321
Security Fabric topology views.....	2324
Security Fabric Rating.....	2325
FortiTelemetry.....	2325
Configuring the Fortinet Security Fabric.....	2326
Forming the Security Fabric.....	2326
Setting up data collection with FortiAnalyzer.....	2331

Adding a FortiSandbox to the Security Fabric.....	2333
Adding a FortiManager to the Security Fabric.....	2334
Adding FortiClient EMS to the Security Fabric.....	2335
Using the Fortinet Security Fabric.....	2337
Understanding the Security Fabric dashboard widgets.....	2337
Viewing the Security Fabric topology.....	2339
Running a Security Fabric Rating.....	2344
Automation stitches.....	2349
Trigger events.....	2349
Response actions.....	2351
Creating automation stitches.....	2353
Configuring an automation, trigger, and action in the CLI.....	2355
Chaining and delaying actions for AWS Lambda and webhook.....	2359
Diagnose commands for automation stitches.....	2359
Fabric Connectors.....	2362
Available services for Fabric Connectors.....	2362
Configuring Fabric Connectors.....	2363
Verifying Fabric Connector status.....	2366
Central management with FortiManager.....	2368
Configuring the FortiManager.....	2368
FortiGuard.....	2370
Firmware updates.....	2377
Administrative domains.....	2377
Backing up and restoring configurations.....	2377
FortiManager in backup mode.....	2377
Related resources.....	2379
Chapter 21 - Security Profiles.....	2380
What's new in FortiOS 6.0.1.....	2381
What's new in FortiOS 6.0.....	2381
Inside FortiOS: AntiVirus.....	2382
Advanced protection against malware and APTs.....	2382
Features.....	2382
Inside FortiOS: Application Control.....	2386
Enhance control and network visibility.....	2386
Features.....	2387
Recipes.....	2389
Inside FortiOS: Intrusion Prevention System (IPS).....	2390
World class next generation IPS capabilities.....	2390
Features.....	2390
Inside FortiOS: Web Filtering.....	2395
Intelligent and effective content control.....	2395
Features.....	2396

Security profiles overview.....	2400
Traffic inspection.....	2400
Content inspection and filtering.....	2402
Security profile components.....	2405
Security profiles/lists/sensors.....	2407
Inspection modes.....	2408
Proxy-based inspection.....	2408
Flow-based inspection.....	2408
Changing between proxy and flow mode.....	2409
Comparison of inspection types.....	2410
Individual security profile considerations.....	2411
Proxy mode and flow mode antivirus and web filter profile options.....	2411
AntiVirus.....	2416
Antivirus concepts.....	2416
Enabling AntiVirus scanning.....	2428
Testing your antivirus configuration.....	2434
Example scenarios.....	2434
Web filter.....	2441
Web filter concepts.....	2441
Inspection modes.....	2443
FortiGuard Web Filtering Service.....	2444
Configuring web filter profiles.....	2450
Overriding FortiGuard website categorization.....	2455
Using cookies to authenticate users in a Web Filter override.....	2462
Web Profile Overrides.....	2463
SafeSearch.....	2464
YouTube Education Filter.....	2465
Static URL filter.....	2466
Web content filter.....	2471
Web filtering example.....	2474
Advanced web filter configurations.....	2477
DNS filter.....	2482
Application control.....	2485
Application control concepts.....	2485
Enabling application control in profile-based modes.....	2486
Application control actions.....	2489
Application considerations.....	2490
Application control monitor.....	2490
Application control examples.....	2491
Intrusion prevention.....	2495
IPS concepts.....	2495
Enabling IPS scanning.....	2498

IPS processing in an HA cluster.....	2501
Configure IPS options.....	2501
Enabling IPS packet logging.....	2506
Other IPS examples.....	2506
Anti-spam filter.....	2513
Anti-spam concepts.....	2513
Anti-spam techniques.....	2513
Configuring Anti-spam.....	2517
Order of spam filtering.....	2519
Spam actions.....	2520
Anti-spam examples.....	2521
Data leak prevention.....	2523
Data leak prevention concepts.....	2523
Enable data leak prevention.....	2528
Creating/editing a DLP sensor.....	2529
DLP archiving.....	2531
DLP examples.....	2532
ICAP support.....	2537
The protocol.....	2537
Offloading using ICAP.....	2538
Configuring ICAP.....	2538
Example ICAP sequence.....	2539
Example ICAP scenario.....	2539
FortiClient Compliance Profiles.....	2541
Endpoint protection overview.....	2541
Configuring endpoint protection.....	2543
Configuring endpoint registration over a VPN.....	2548
Assigning FortiClient Profiles using Microsoft AD user groups.....	2550
Modifying the endpoint protection replacement messages.....	2552
Monitoring endpoints.....	2552
Proxy options.....	2554
The use of different proxy profiles and profile options.....	2554
Proxy Options profile components.....	2554
SSL/SSH inspection.....	2557
SSL inspection.....	2557
Why use SSL inspection.....	2560
SSL certificate inspection.....	2561
Creating or editing an SSL/SSH Inspection profile.....	2562
Secure white list database.....	2564
SSH MITM deep inspection.....	2564
SSL server table for SSL offloading.....	2568
Custom Application & IPS Signatures.....	2569

Creating a custom IPS signature.....	2569
Custom signature syntax.....	2569
Custom signature keywords.....	2570
Creating a custom signature to block access to example.com.....	2582
Creating a custom signature to block the SMTP “vrfy” command.....	2584
Creating a custom signature to block files according to the file's hash value.....	2585
Other security profiles considerations.....	2587
Global security profiles across Virtual domains (VDOMs).....	2587
Conserve mode.....	2587
Using wildcards and Perl regular expressions.....	2589
Control how sessions are distributed to Fortinet processes.....	2592
CPU allocation and tuning commands to survive reboot.....	2592
Excluding industrial IP signatures.....	2592
Chapter 22 - Server Load Balancing.....	2594
Inside FortiOS: Server Load Balancing.....	2594
Server Load Balancing combined with NGFW and UTM protection.....	2594
SSL/TLS offloading.....	2595
SSL/TLS content inspection.....	2596
Health Check.....	2596
Server Monitoring and Management.....	2596
HTTP Multiplexing.....	2596
Basic load balancing configuration example.....	2597
Configuring load balancing.....	2601
Load balancing and other FortiOS features.....	2603
Configuring load balancing from the GUI.....	2603
Configuring load balancing from the CLI.....	2605
Load balancing methods.....	2606
Session persistence.....	2607
Real servers.....	2607
Health check monitoring.....	2609
Load balancing limitations.....	2611
Monitoring load balancing.....	2612
Load balancing diagnose commands.....	2613
HTTP and HTTPS load balancing, multiplexing, and persistence.....	2614
HTTP and HTTPS multiplexing.....	2614
HTTP and HTTPS persistence.....	2615
HTTP host-based load balancing.....	2617
SSL/TLS load balancing.....	2619
SSL/TLS offloading.....	2619
Separate virtual-server client and server TLS version and cipher configuration.....	2621
Setting the SSL/TLS versions to use for server and client connections.....	2621
Setting the SSL/TLS cipher choices for server and client connections.....	2622

Protection from TLS protocol downgrade attacks.....	2623
Setting 3072- and 4096-bit Diffie-Hellman values.....	2623
Additional SSL load balancing and SSL offloading options.....	2623
SSL offloading support for Internet Explorer 6.....	2624
Selecting the cipher suites available for SSL load balancing.....	2625
Disabling SSL/TLS re-negotiation.....	2625
IP, TCP, and UDP load balancing.....	2629
Example HTTP load balancing to three real web servers.....	2629
GUI configuration.....	2630
CLI configuration.....	2633
Example Basic IP load balancing configuration.....	2634
Example Adding a server load balance port forwarding virtual IP.....	2635
Example Weighted load balancing configuration.....	2636
GUI configuration.....	2636
CLI configuration.....	2638
Example HTTP and HTTPS persistence configuration.....	2639
CLI configuration: adding persistence for a specific domain.....	2642
Chapter 23 - SSL VPN.....	2644
What's new in FortiOS 6.0.1.....	2644
What's new in FortiOS 6.0.....	2644
Overview.....	2645
SSL VPN modes of operation.....	2646
Port forwarding mode.....	2647
SSL VPN conserve mode.....	2649
Traveling and security.....	2650
SSL VPN and IPv6.....	2650
Basic configuration.....	2651
User accounts and groups.....	2651
Configuring SSL VPN web portals.....	2656
Configuring security policies.....	2665
Configuring encryption key algorithms.....	2671
Additional configuration options.....	2672
The SSL VPN client.....	2683
FortiClient.....	2683
Tunnel mode client configuration.....	2683
The SSL VPN web portal.....	2685
Connecting to the FortiGate unit.....	2685
Web portal overview.....	2685
Portal configuration.....	2687
Using the Bookmarks widget.....	2692
Using the Quick Connection Tool.....	2694
Using FortiClient.....	2698

Setup examples	2699
Secure Internet browsing	2699
Split tunnel	2701
Multiple user groups with different access permissions	2704
Client device certificate authentication with multiple groups	2709
Troubleshooting	2710
Chapter 24 - System Administration	2713
What's new in FortiOS 6.0	2713
Administrators	2714
Administrator profiles	2714
Adding a local administrator	2715
LDAP authentication for administrators	2716
Other methods of administrator authentication	2717
Administrator lockout	2718
Monitoring administrators	2719
Management access	2719
Security precautions	2720
Monitoring	2723
Dashboard	2723
sFlow support	2723
Monitor menus	2725
Logging	2725
Alert email	2726
SNMP	2727
SNMP get command syntax	2735
Replacement messages	2737
Administration for schools	2743
PPTP and L2TP	2746
How PPTP VPNs work	2746
FortiGate unit as a PPTP server	2748
Configuring the FortiGate unit for PPTP VPN	2751
Configuring the FortiGate unit for PPTP passthrough	2751
Testing PPTP VPN connections	2753
Logging VPN events	2753
Configuring L2TP VPNs	2754
L2TP configuration overview	2756
Session helpers	2760
Viewing the session helper configuration	2760
Changing the session helper configuration	2761
DCE-RPC session helper (dcerpc)	2763
DNS session helpers (dns-tcp and dns-udp)	2764
File transfer protocol (FTP) session helper (ftp)	2764

H.323 and RAS session helpers (h323 and ras).....	2764
H.245 session helper (h245).....	2765
Media Gateway Controller Protocol (MGCP) session helper (mgcp).....	2765
ONC-RPC portmapper session helper (pmap).....	2766
PPTP session helper for PPTP traffic (pptp).....	2766
Remote shell session helper (rsh).....	2767
Real-Time Streaming Protocol (RTSP) session helper (rtsp).....	2767
Session Initiation Protocol (SIP) session helper (sip).....	2768
Trivial File Transfer Protocol (TFTP) session helper (tftp).....	2768
Oracle TNS listener session helper (tns).....	2768
Advanced concepts.....	2769
Single firewall vs. multiple virtual domains.....	2769
Modem.....	2771
Assigning IP address by MAC address.....	2774
IP addresses for self-originated traffic.....	2775
Disk.....	2775
CLI scripts.....	2776
Rejecting PING requests.....	2778
Opening TCP 113.....	2778
Obfuscate HTTP responses from SSL VPN.....	2779
Blocking land attacks in transparent mode.....	2779
Multi-dimension tagging.....	2779
Chapter 25 - Traffic Shaping.....	2781
What's new in FortiOS 6.0.....	2781
The purpose of traffic shaping.....	2782
QoS.....	2782
Traffic policing.....	2783
Bandwidth guarantee, limit, and priority interactions.....	2784
FortiGate traffic.....	2785
Through traffic.....	2785
Important considerations.....	2789
Traffic shaping methods.....	2791
Traffic shaping options.....	2791
Shared policy traffic shaping.....	2792
Per-IP traffic shaping.....	2797
Application control shaping.....	2800
Reverse direction traffic shaping.....	2802
Enabling traffic shaping in the security policy.....	2803
Scheduling traffic shaping policies.....	2803
ToS priority.....	2804
Interface-based traffic shaping.....	2805
Differentiated services.....	2811

DSCP examples.....	2812
Traffic mapping.....	2816
Traffic shaper monitor.....	2817
Examples.....	2818
QoS using priority from security policies.....	2818
QoS using priority from ToS or DiffServ.....	2822
Example setup for VoIP.....	2823
Troubleshooting traffic shaping.....	2829
Interface diagnosis.....	2829
Traffic shaper diagnose commands.....	2829
Packet lost with the debug flow.....	2831
Session list details with dual traffic shaper.....	2831
Additional information.....	2831
Chapter 26 - Transparent Mode.....	2833
What's new in FortiOS 6.0.....	2833
Transparent mode overview.....	2834
What is transparent mode?.....	2834
Transparent mode features.....	2834
Installation.....	2836
Installing a FortiGate in transparent mode.....	2836
Using a virtual wire pair to simplify transparent mode.....	2837
Management IP configuration.....	2838
Networking in transparent mode.....	2840
Static routing.....	2840
Packet forwarding.....	2841
Network address translation (NAT).....	2846
VLANs and forwarding domains.....	2848
Inter-VDOM links between NAT/route and transparent VDOMs.....	2851
Replay traffic scenario.....	2851
Packet forwarding using Cisco protocols.....	2852
Configuration example.....	2853
Firewalls and security in transparent mode.....	2856
Firewall policy look up.....	2856
Firewall session list.....	2856
Security scanning.....	2857
IPsec VPN in transparent mode.....	2858
Using IPsec VPNs in transparent mode.....	2858
Example 1: Remote sites with different subnets.....	2859
Example 2: Remote sites on the same subnet.....	2865
Using FortiManager and FortiAnalyzer.....	2872
High availability in transparent mode.....	2873
Virtual clustering.....	2873

MAC address assignment	2874
Best practices	2875
Chapter 27 - Troubleshooting	2876
Troubleshooting methodologies	2877
Ensure you have administrator-level access to required equipment	2877
Establish a baseline	2877
Define the problem	2878
Create a troubleshooting plan	2879
Obtain any required equipment	2880
Consult Fortinet resources	2880
Troubleshooting tools	2881
FortiOS diagnostics	2881
FortiOS ports	2903
FortiAnalyzer and FortiManager ports	2904
FortiGuard troubleshooting	2904
Troubleshooting tips	2908
How to check hardware connections	2909
How to check FortiOS network settings	2910
How to check CPU and memory resources	2911
How to check modem status	2917
How to run ping and traceroute	2917
How to check the logs	2921
How to verify the contents of the routing table (in NAT mode)	2922
How to verify the correct route is being used	2923
How to verify the correct firewall policy is being used	2924
How to check the bridging information in transparent mode	2924
How to check the number of sessions that UTM proxy uses	2925
How to examine the firewall session list	2929
How to check wireless information	2930
How to verify connectivity to FortiGuard	2931
How to perform a sniffer trace (CLI and packet capture)	2931
How to debug the packet flow	2934
Troubleshooting resources	2936
Technical documentation	2936
Fortinet video library	2936
Release notes	2936
Knowledge base	2936
Fortinet technical discussion forums	2936
Fortinet training services online campus	2936
Fortinet customer support	2936
Chapter 28 - Virtual Domains	2937
What's new in FortiOS 6.0	2937

VDOMs overview.....	2938
Benefits of virtual domains.....	2938
Enabling and accessing VDOMs.....	2939
Configuring additional VDOMs.....	2943
VDOMs in NAT mode.....	2949
Using a VDOM in NAT/route mode.....	2949
Example configuration: VDOM in NAT/route mode.....	2953
VDOMs in transparent mode.....	2964
Transparent mode overview.....	2964
Operation mode differences in VDOMs.....	2965
Using a VDOM in transparent mode.....	2966
Example configuration: VDOM in transparent mode.....	2967
Security profiles and VDOMs.....	2981
VDOM-level security profiles.....	2981
Global security profiles.....	2981
Inter-VDOM routing.....	2982
Benefits of inter-VDOM routing.....	2982
Inter-VDOM configurations.....	2983
Configuring VDOM links.....	2986
Dynamic routing over inter-VDOM links.....	2989
HA virtual clusters and VDOM links.....	2990
Example configuration: inter-VDOM routing.....	2991
Troubleshooting VDOMs.....	3014
VDOM admin having problems gaining access.....	3014
FortiGate running very slowly.....	3014
General VDOM tips and troubleshooting.....	3015
Virtual FortiOS (Private Cloud Administration Guide).....	3019
What's new in virtual FortiOS 6.0.1.....	3019
What's new in virtual FortiOS 6.0.....	3019
Virtual FortiOS overview.....	3021
FortiGate VM models and licensing.....	3021
Registering FortiGate VM.....	3022
Downloading the FortiGate VM deployment package.....	3022
Deployment package contents.....	3023
Deploying the FortiGate VM appliance.....	3025
Performance and optimization.....	3025
Other virtual FortiOS products.....	3026
Deployment example – VMware.....	3037
Open the FortiGate VM OVF file with the vSphere client.....	3037
Configure FortiGate VM hardware settings.....	3042
Transparent mode VMware configuration.....	3043
High availability VMware configuration.....	3043

Power on your FortiGate VM.....	3044
Deployment example – MS Hyper-V.....	3045
Create the FortiGate VM virtual machine.....	3045
Configure FortiGate VM hardware settings.....	3052
High availability Hyper-V configuration.....	3063
Start the FortiGate VM.....	3064
Deployment example – KVM.....	3065
Create the FortiGate VM virtual machine.....	3065
Configure FortiGate VM hardware settings.....	3067
Start the FortiGate VM.....	3068
Deployment example – Open Xen.....	3069
Create the FortiGate VM virtual machine.....	3069
Deployment example – Citrix XenServer.....	3075
Create the FortiGate VM virtual machine (XenCenter).....	3075
Configure virtual hardware.....	3078
FortiGate VM initial configuration.....	3082
Set FortiGate VM port1 IP address.....	3082
Connect to the FortiGate VM web-based manager.....	3085
Upload the FortiGate VM license file.....	3085
Validate the FortiGate VM license with FortiManager.....	3087
Configure your FortiGate VM.....	3089
Chapter 30 - VoIP Solutions: SIP.....	3090
What's new in FortiOS 6.0.1.....	3091
What's new in FortiOS 6.0.....	3091
Inside FortiOS: Voice over IP (VoIP) protection.....	3092
Advanced voice over IP protection.....	3092
Carrier grade protection.....	3094
NAT/NAPT.....	3094
SIP ALG activation.....	3096
SIP over IPv6.....	3097
Platform support and hardware acceleration.....	3097
Common SIP VoIP configurations.....	3098
Peer to peer configuration.....	3098
SIP proxy server configuration.....	3098
SIP redirect server configuration.....	3099
SIP registrar configuration.....	3100
SIP with a FortiGate.....	3101
SIP messages and media protocols.....	3104
Hardware accelerated RTP processing.....	3106
SIP request messages.....	3106
SIP response messages.....	3107
SIP message start line.....	3109

SIP headers	3109
The SIP message body and SDP session profiles	3111
Example SIP messages	3114
The SIP session helper	3116
SIP session helper configuration overview	3116
Viewing, removing, and adding the SIP session helper configuration	3117
Changing the port numbers that the SIP session helper listens on	3117
Configuration example: SIP session helper in transparent mode	3118
SIP session helper diagnose commands	3121
The SIP ALG	3122
Enabling VoIP support from the GUI	3124
SIP ALG configuration overview	3124
VoIP profiles	3124
Changing the port numbers that the SIP ALG listens on	3126
Disabling the SIP ALG in a VoIP profile	3126
SIP ALG diagnose commands	3126
Conflicts between the SIP ALG and the session helper	3128
Stateful SIP tracking, call termination, and session inactivity timeout	3129
Adding a media stream timeout for SIP calls	3129
Adding an idle dialog setting for SIP calls	3130
Changing how long to wait for call setup to complete	3130
SIP and RTP/RTCP	3131
How the SIP ALG creates RTP pinholes	3132
Configuration example: SIP in transparent mode	3134
General configuration steps	3134
Configuration steps - GUI	3134
Configuration steps - CLI	3136
RTP enable/disable (RTP bypass)	3137
Opening and closing SIP register, contact, via and record-route pinholes	3138
Accepting SIP register responses	3139
How the SIP ALG performs NAT	3140
SIP ALG source address translation	3140
SIP ALG destination address translation	3141
SIP call re-invite messages	3141
How the SIP ALG translates IP addresses in SIP headers	3141
How the SIP ALG translates IP addresses in the SIP body	3144
SIP NAT scenario: source address translation (source NAT)	3145
SIP NAT scenario: destination address translation (destination NAT)	3147
SIP NAT configuration example: source address translation (source NAT)	3150
SIP NAT configuration example: destination address translation (destination NAT)	3152
SIP and RTP source NAT	3156
SIP and RTP destination NAT	3156

Source NAT with an IP pool.....	3158
Different source and destination NAT for SIP and RTP.....	3158
NAT with IP address conservation.....	3159
Controlling how the SIP ALG NATs SIP contact header line addresses.....	3160
Controlling NAT for addresses in SDP lines.....	3161
Translating SIP session destination ports.....	3161
Translating SIP sessions to multiple destination ports.....	3163
Adding the original IP address and port to the SIP message header after NAT.....	3164
Enhancing SIP pinhole security.....	3165
Hosted NAT traversal.....	3168
Configuration example: Hosted NAT traversal for calls between SIP Phone A and SIP Phone B.....	3169
Hosted NAT traversal for calls between SIP Phone A and SIP Phone C.....	3173
Restricting the RTP source IP.....	3173
SIP over IPv6.....	3174
Deep SIP message inspection.....	3175
Actions taken when a malformed message line is found.....	3176
Logging and statistics.....	3176
Deep SIP message inspection best practices.....	3176
Configuring deep SIP message inspection.....	3177
Blocking SIP request messages.....	3180
SIP rate limiting.....	3182
Limiting the number of SIP dialogs accepted by a security policy.....	3184
SIP logging.....	3185
Inspecting SIP over SSL/TLS (secure SIP).....	3186
Adding the SIP server and client certificates.....	3188
Adding SIP over SSL/TLS support to a VoIP profile.....	3188
SIP and HA—session failover and geographic redundancy.....	3190
SIP geographic redundancy.....	3190
Supporting geographic redundancy when blocking OPTIONS messages.....	3191
Support for RFC 2543-compliant branch parameters.....	3192
SIP and IPS.....	3193
SIP debugging.....	3194
SIP debug log format.....	3194
SIP-proxy filter per VDOM.....	3195
SIP-proxy filter command.....	3195
SIP debug setting.....	3195

Chapter 1 - What's New for FortiOS 6.0

Fortinet Security Fabric

This section introduces new Security Fabric features in FortiOS 6.0.

Security Fabric automation

User-defined Automations allow you to improve response times to security events by automating the activities between devices in the Security Fabric. You can monitor events from any source in the Security Fabric and set up action responses to any destination. To create an Automation, you can set up a Trigger event and response Actions that cause the Security Fabric to respond in a predetermined way. From the root FortiGate, you can set up event triggers for the following event types: compromised host, event log, reboot, conserve mode, high CPU, license expiry, High Availability (HA) failover, and configuration changes. The workflows have the means to launch the following actions in response: email, FortiExplorer notification, AWS Lambda and webhook. Additional actions are available for compromised hosts, such as: access layer quarantine, quarantine FortiClient via EMS, and IP ban.

FortiOS 6.0.2 adds the ability to test automation stitches using the `diagnose automation test` command.

For more information, see [Using the Fortinet Security Fabric on page 2337](#).

Security rating

The Security Rating feature (previously called the Security Fabric Audit) includes new security checks that can help you make improvements to your organization's network, such as enforce password security, apply recommended login attempt thresholds, encourage two factor authentication, and more.

For more information, see the [Fortinet Recommended Security Best Practices](#) document.

Security rating FortiGuard service

Security Rating is now a subscription service that FortiGuard offers when you purchase a Security Rating license. This service allows you to:

- Dynamically receive updates from FortiGuard.
- Run Security Rating checks for each licensed device in a Security Fabric.
- Run Security Rating checks in the background or on demand.
- Submit rating scores to FortiGuard and receive rating scores from FortiGuard, for ranking customers by percentile.

For more information, see [Using the Fortinet Security Fabric on page 2337](#).

Solution and service integration

In FortiOS 6.0, the Security Fabric extends to include more Fortinet products.

Wireless user quarantine

When you create or edit an SSID, you can enable the **Quarantine Host** option to quarantine devices that are connected in Tunnel-mode. The option to quarantine a device is available from the **Topology** and **FortiView** WiFi pages.

When a host is put into the quarantine VLAN, it gets an IP address from the quarantine VLAN DHCP server, and becomes part of the quarantined network.

For more information, see [Features for high-density deployments on page 1131](#).

Fortinet products can join the Security Fabric by serial number

Fortinet products can now easily and securely join the Security Fabric using an authorized device serial number.

For more information, see [Using the Fortinet Security Fabric on page 2337](#).

FortiMail integration

You can now add a FortiMail stats widget to the FortiGate Dashboard page to show mail detection stats from FortiMail. Other FortiMail integrations include the following:

- A FortiMail section that displays the FortiMail name, IP address, login and password is now available in the Security Fabric Settings page.
- FortiMail is now shown as a node in the topology tree view in the Fabric Settings page and in the Physical Topology and Logical Topology views.
- The topology views now show the number of FortiMail devices in the Security Fabric in the device summary.

For more information, see [Using the Fortinet Security Fabric on page 2337](#).

Synchronize the FortiManager IP address among all Security Fabric members

When you add a FortiManager to the root FortiGate of the Security Fabric, its configuration is now automatically synchronized with all devices in the Security Fabric. Central management features are now configured from the Security Fabric Settings page.

For more information, see [Using the Fortinet Security Fabric on page 2337](#).

Improve FortiAP and FortiSwitch support in Security Fabric views

The Security Fabric widget on the dashboard and the Security Fabric Settings page now show the FortiAP and FortiSwitch devices in the Security Fabric.

- You can now use new shortcuts to easily authorize any newly discovered devices and manage them.
- Switch stacking is now supported in the Physical and Logical topology views, and Inter-switch Link (ISL-LAG) is now identified by a thicker single line.

For more information, see [Using the Fortinet Security Fabric on page 2337](#).

EMS server support in Security Fabric topology

The FortiClient Endpoint Management System (EMS) can be enabled in FortiClient Endpoint profiles. This feature allows you to maintain FortiClient endpoint protection from FortiClient EMS and dynamically push configuration changes from the EMS to FortiClient endpoints. EMS server support is also integrated with Security Fabric Automation.

For more information, see [Using the Fortinet Security Fabric on page 2337](#).

Multi-cloud support (Security Fabric connectors)

Security Fabric multi-cloud support adds Security Fabric connectors to the Security Fabric configuration. Security Fabric connectors allow you to integrate Application Centric Infrastructure (ACI), Amazon Web Services (AWS), Microsoft Azure, VMware NSX, and Nuage Virtualized Services Platform configurations into the Security Fabric.

Additionally Cloud init support for Azure is now native to the cloud. FortiGate VM for Azure also supports bootstrapping.

For more information, see [Fabric Connectors on page 2362](#) and [Other virtual FortiOS products on page 3026](#).

Azure regional support

The Azure Security Fabric connector supports connecting to regional Azure public clouds. This change allows organizations in different regions to connect to their regional Azure public cloud if required for compliance or performance reasons.

For more information, see [Fabric Connectors on page 2362](#) and [Other virtual FortiOS products on page 3026](#).

GUI change for single sign-on configuration

In FortiOS 6.0.1, the options to configure single sign-on in the FortiGate GUI are now located in the **Security Fabric > Fabric Connectors** menu.

Manageability

This section introduces new manageability features in FortiOS 6.0.

Asset tagging

You can use the new Asset Tagging system to create tags to separate and categorize network objects, interfaces, and devices. Tags are flexible, easy to configure, and useful for comprehensive monitoring, audit reporting, and more.

For more information, see [Multi-dimension tagging on page 2779](#).

FortiSwitch network assisted device detection and destination name resolution

Device detection now extends to managed FortiSwitches since some devices may not be visible to the FortiGate that manages them. Devices that are connected to a FortiSwitch are more visible to the FortiGate that manages them and to the Security Fabric.

FortiSwitch destination name resolution clearly presents destination objects and the aggregation of related IP addresses with domains. It also applies Internet Service Database (ISDB) mapping for destination data.

For more information, see [Managing “bring your own device” on page 1892](#) and [FortiLink configuration using the FortiGate GUI on page 1921](#).

Global security profiles

Global Security Profiles can be used by multiple VDOMs instead of creating identical profiles for each VDOM. You can create global security profiles for the following security features:

- Antivirus
- Application control
- Data leak prevention
- Intrusion protection
- Web filtering

For more information, see [Global security profiles on page 2981](#).

Networking

This section introduces new networking features in FortiOS 6.0.

SD-WAN improvements

FortiOS 6.0 introduces the following SD-WAN features:

- Multiple server support for health checks
- Internet service groups
- Bandwidth options in SD-WAN rules
- Custom profiles in SD-WAN rules
- DSCP tagging of forwarded packets in SD-WAN rules

For more information, see [SD-WAN on page 2273](#).

Multipath intelligence and performance SLAs

SD-WAN performance Service-Level Agreements (SLAs) incorporate multilayer SLA monitoring of link selection. To help handle emergency load or outages you can select links based on weight and SLA priority and then return to defaults once the network stabilizes. Also, traffic shaping and application intelligence have been added to the SD-WAN configuration, which gives you more control of SD-WAN traffic.

For more information, see [SD-WAN on page 2273](#).

Application awareness

You can now use application control and application control group options in SD-WAN rules.

Internet Service support is also increased from a single Internet Service to Internet Service groups.

For more information, see [Application control settings in SD-WAN rules on page 2273](#).

BGP dynamic routing and IPv6 support for SD-WAN

FortiOS 6.0 introduces support for dynamic router for an SD-WAN configuration. You can set up a route map and add a route tag to the route map. Then, you can create an SD-WAN configuration, a health check, and a service for it. When you create the service, you add the configured route tag that you created in the route map to the service.

For more information, see [SD-WAN on page 2273](#).

Interface-based traffic shaping

In FortiOS 6.0, you can now enable traffic shaping on an interface. Interface-based traffic shaping allows you to enforce bandwidth limits by traffic type for individual interfaces.

For more information, see [Interface-based traffic shaping on page 2805](#).

Cloud-assisted one-click VPN

One-click VPN (OCVPN) is a cloud-based solution that greatly simplifies the provisioning and configuration of IPsec VPN. The administrator enables OCVPN with a single click, adds the required subnets, and then the configuration is complete. The OCVPN updates each FortiGate automatically as devices join and leave the VPN, as subnets are added and removed, when dynamic external IP addresses change (for example, DHCP or PPPoE), and when WAN interface bindings change (as in the case of dual WAN redundancy).

For more information, see [One-Click VPN \(OCVPN\) on page 1719](#).

IPv6 enhancements

The following new IPv6 features have been added.

- IPv6 captive portal
- IPv6 FQDN and wildcard firewall addresses
- IPv6 ISIS dynamic routing
- DHCPv6 server prefix delegation
- IPv6 DFD and VRRP

For more information, see [IPv6 on page 613](#).

NAT enhancements

The following new NAT features have been added.

- Central source NAT (SNAT) policies now include a comment field
- Port block allocation timeout is configurable
- NAT46 IP pools
- VRRP HA supports firewall virtual IPs (VIPs) and IP pools

For more information, see [NAT on page 559](#).

EMAC-VLAN support

The media access control (MAC) virtual local area network (VLAN) feature in Linux allows you to configure multiple virtual interfaces with different MAC addresses (and therefore different IP addresses) on a physical interface.

For more information, see [Enhanced MAC VLANs on page 2049](#).

Security

This section introduces new security features in FortiOS 6.0.

FortiGuard virus outbreak prevention

FortiGuard virus outbreak prevention is an additional layer of protection that keeps your network safe from newly emerging malware. Quick virus outbreaks can infect a network before signatures can be developed to stop them. Outbreak protection stops these virus outbreaks until signatures become available in FortiGuard.

For more information, see [FortiGuard virus outbreak prevention on page 2432](#).

FortiGuard content disarm and reconstruction

Content Disarm and Reconstruction (CDR) removes exploitable content and replaces it with content that's known to be safe. As files are processed through an enabled AntiVirus profile, content that's found to be malicious or unsafe is replaced with content that allows the traffic to continue, but doesn't put the recipient at risk.

Content that can be scanned includes PDF and Microsoft Office files leaving the network on CDR-supported protocols (such as, HTTP web download, SMTP email send, IMAP and POP3 email retrieval—MAPI isn't supported).

This feature works even if FortiSandbox is not configured, but only if you want to discard the original file. If FortiSandbox is configured and it responds that the file is clean, it passes the content unmodified.

For more information, see [Content Disarm and Reconstruction \(CDR\) on page 2429](#).

Application groups for NGFW policies

When a FortiGate operates in NGFW policy mode, you can create application groups when you add NGFW policies. Then, when you add IPv4 or IPv6 policies you can create application groups to simplify policy creation.

For more information, see [Application groups for NGFW policies on page 532](#).

Application control rule sequencing

To have more control over application control outcomes, you can control the order that application signatures appear in application control sensors. Signatures for applications that are more sensitive can appear higher in the list so they get matched first.

For more information, see [Application control on page 2485](#).

Threat Feeds (external dynamic block lists)

This feature introduces the ability to dynamically import external block lists from an HTTP server. You can use the block lists to enforce special security requirements that your organization has. This can include long term policies to always block access to some websites or short time requirements to block access to known compromised locations. Since the lists are dynamically imported any changes made to the list are instantly imported by FortiOS. Dynamic block lists can be added to:

- Web Filter profiles and SSL inspection exemptions.
- DNS Filter profiles and "Source/Destination" addresses in proxy policies.

In each profile, the administrator can configure multiple external block lists.

For more information, see [Threat Feed Connectors on page 2462](#).

FortiAP-S bridge mode security profiles

If you have enabled bridge mode for a managed FortiAP-S, you can add a UTM profile to the wireless controller configuration that allows you to apply the following security profile features to all traffic accepted by the managed FortiAP-S:

- AntiVirus (including Botnet protection),
- IPS,
- Application control, and
- Web Filtering.

For more information, see [FortiAP-S bridge mode security profiles on page 1144](#).

Chapter 2 - Getting Started

- [Installation](#) discusses installing a FortiGate in your network.
- [Using the GUI](#) highlights features of the graphical user interface (GUI).
- [Using the CLI](#) provides a high level overview of the command line interface (CLI) for FortiOS.
- [FortiExplorer for iOS](#) provides instructions for connecting to a FortiGate using the FortiExplorer for iOS app.
- [LED Specifications](#) presents a short guide to LED status indicators.
- [Inspection Mode](#) summarizes proxy-based and flow-based inspection modes.
- [Basic administration](#) explains basic tasks for setting up a new FortiGate and for updating firmware.
- [Troubleshooting your FortiGate installation](#) provides troubleshooting tips if your FortiGate installation is unsuccessful.
- [Resources](#) provides a list of documents to help you with more advanced FortiGate configurations.

Differences between models

Before you get started, note that not all FortiGate models have the same features. This is especially true of the desktop or entry-level models: FortiGate / FortiWiFi models 30 to 90. If you are using one of these FortiGate models, you may have some difficulties accessing certain features.

The entry-level, or desktop, models can connect to the internet in two simple steps. They also have a number of features that are only available using the CLI, rather than appearing in the GUI.

- [Quick installation using DHCP](#)
- [CLI-only features](#)

Consult your model's Quick Start Guide, [hardware manual](#), or the [Feature / Platform Matrix](#) for further information about features that vary by model.

The Fortinet Cookbook site has a section on [hardware](#) that provides how-to recipes and articles on features that are unique to certain models.

FortiGate models differ principally by the names used and the features available:

- Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called **lan**, while on other units it is called **internal**.
- Certain features are not available on all models. Additionally, a particular feature may be available only through the CLI on some models, while that same feature may be viewed in the GUI on other models.

If you believe your FortiGate model supports a feature that does not appear in the GUI, go to **System > Feature Visibility** and confirm that the feature is enabled. For more information, see [Feature Visibility on page 69](#).

What's new in FortiOS 6.0

The following list contains new getting started features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- [New dashboard widget for "Botnet Activity" on page 68](#)
- [Dashboard widget improvements for "Administrators" on page 67](#)
- ["Modifying dashboard widget titles" on page 68](#)

Installation

This section discusses how to install your FortiGate and use it in your network, after completion of the initial setup outlined in the FortiGate model's Quick Start Guide.

The following topics are included in this section:

- [Quick installation using DHCP](#)
- [Installing a FortiGate in NAT/Route mode](#)
- [Using a virtual wire pair](#)

Quick installation using DHCP

Most of the FortiGate desktop models have a default configuration that includes a DHCP server on the **lan** (or **internal**) interface and a security policy that securely allows all sessions from the internal network to reach the Internet. Because of this, you can connect your desktop FortiGate to the Internet in two simple steps:

Note that, in order to use this installation method, your ISP must provide connectivity with DHCP and accept DHCP requests without authentication. You must also use IPv4 to connect your FortiGate to the Internet.

1. Connect the **wan** interface on your FortiGate to your ISP-supplied equipment, and connect the internal network to the default **lan** interface on your FortiGate. Turn on the ISP's equipment, the FortiGate, and the computers on the internal network.
2. For computers on the internal network:
 - a. **Windows Vista/7/8/10 users:**
 - i. Go to **Network and Sharing Center** and select **Change adapter settings**.
 - ii. Open the **Local Area Connection** (Ethernet or WiFi, whichever applies) and select **Properties**.
 - iii. Select **Internet Protocol Version 4 (TCP/IPv4)** and then select **Properties**.
 - iv. Select **Obtain an IP address automatically** and **Obtain DNS server address automatically**.
 - v. Click **OK**.
 - b. **Mac OS X users:**
 - i. Go to **System Preferences > Network** and select your Ethernet connection.
 - ii. Set **Configure IPv4** to **Using DHCP**.

Results

To confirm successful Internet connectivity from any computer on the internal network, open a web browser and browse to any website.

Installing a FortiGate in NAT/route mode

There are two main ways to install a FortiGate using network address translation (NAT)/route mode: [Standard installation in NAT/route mode](#), where Internet access is provided by a single Internet service provider (ISP), and [Redundant Internet installation](#), where two ISPs are used.

NAT/Route mode vs. transparent mode

A FortiGate can operate in one of two modes: NAT/route or transparent.

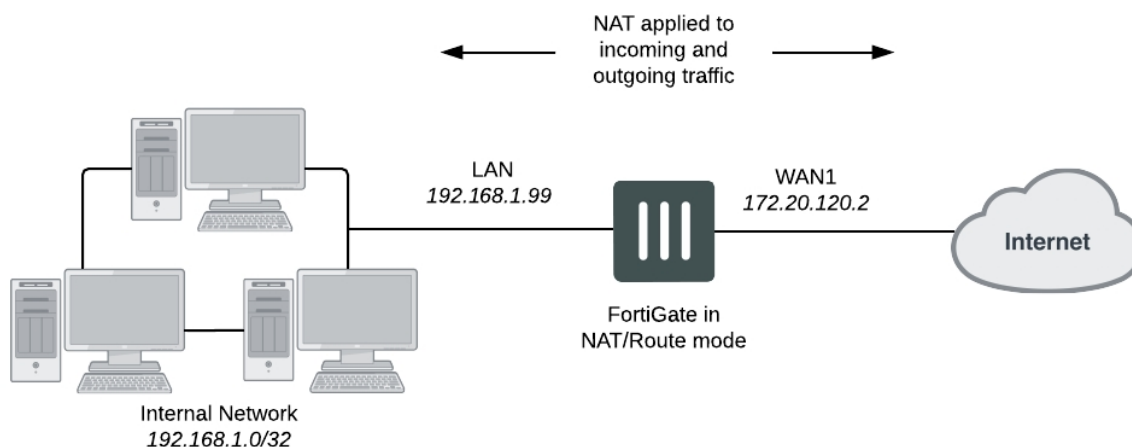

The most common of the two operating modes is NAT/route mode, where a FortiGate is installed as a gateway or router between two networks. In most cases, it is used between a private network and the Internet. This allows the FortiGate to hide the IP addresses of the private network using NAT. NAT/route mode is also used when two or more ISPs provide the FortiGate with redundant Internet connections.

A FortiGate in transparent mode is installed between the internal network and the router. In this mode, the FortiGate does not make any changes to IP addresses and only applies security scanning to traffic. When a FortiGate is added to a network in transparent mode, no network changes are required, except to provide the FortiGate with a management IP address. Transparent mode is used primarily when there is a need to increase network protection but changing the configuration of the network itself is impractical.

For more information about transparent mode, see the [Transparent Mode](#) chapter of the handbook.

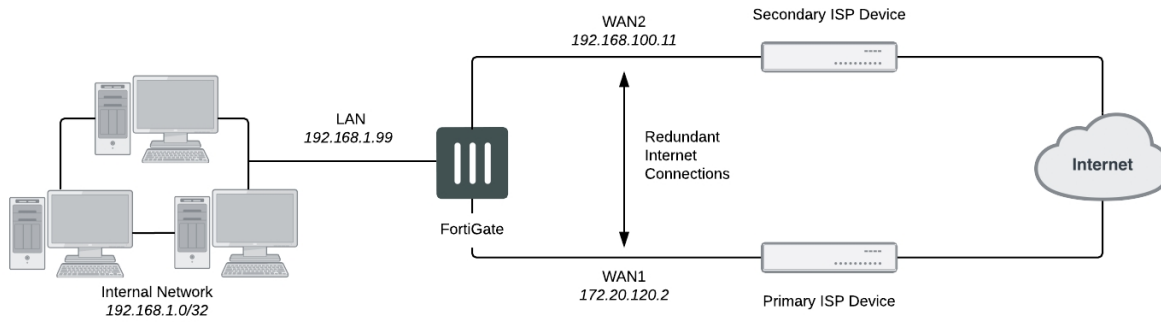

Standard installation in NAT/route mode

In this configuration, a FortiGate is installed as a gateway or router between a private network and the Internet. By using NAT mode, the FortiGate is able to hide the IP addresses of the private network.

Redundant Internet installation

In this configuration, a WAN link interface is created that provides the FortiGate with redundant Internet connections from two ISPs. The WAN link interface combines these two connections, allowing the FortiGate to treat them as a single interface.

Installing a FortiGate with redundant Internet

If you have previously configured your FortiGate using the standard installation, you will have to delete all routes and policies referring to an interface that will be used to provide redundant Internet. This includes the default Internet access policy that is included on many FortiGate models.

1. Connect your ISP devices to your FortiGate's Internet-facing interfaces (typically WAN1 and WAN2).
2. Go to **Network > Interfaces** to create a WAN link interface, which is used to group multiple Internet connections together so that the FortiGate can treat them as a single interface.
3. Set the interface **Status** to **Enable**.
4. Under **SD-WAN Interface Members**, click on the plus sign and then on the down arrow to open the dropdown menu. Select WAN1 as the **Interface** and enter the **Gateway** IP provided by your primary ISP. Do the same for WAN2, but use the Gateway IP provided by your secondary ISP.
5. Select an appropriate method for the **SD-WAN Usage** from the following options, and **Apply** your changes when finished:
 - **Bandwidth** - A bandwidth cap is defined for active members of the SD WAN link.
 - **Volume** - A volume ratio is set for each active member.
 - **Sessions** - A sessions ratio is set for each active member.
6. Go to **Network > Static Routes** and create a new default route. Set **Interface** to the SD-WAN link.
7. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet.

Using a virtual wire pair

A virtual wire pair consists of two interfaces that do not have IP addressing and are treated similar to a transparent mode VDOM. All traffic received by one interface in the virtual wire pair can only be forwarded out the other interface, provided that a virtual wire pair firewall policy allows this traffic. Traffic from other interfaces cannot be routed to the interfaces in a virtual wire pair.

Virtual wire pairs are useful for atypical topologies where MAC addresses do not behave normally. For example, port pairing can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

Virtual wire pairing replaces the port pairing feature available in earlier firmware versions. Unlike port pairing, virtual wire pairing can be used for FortiGate in both NAT/Route and Transparent modes.

In the example configuration below, a virtual wire pair (consisting of port3 and port4) makes it easier to protect a web server that is behind a FortiGate operating as an Internal Segmentation Firewall (ISFW). Users on the internal network will access the web server through the ISFW over the virtual wire pair.

Adding a virtual wire pair and virtual wire pair policy

Interfaces used in a virtual wire pair cannot be used to access the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

1. Go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**.
2. Select the interfaces to add to the virtual wire pair. These interfaces cannot be part of a switch, such as the default **lan/internal** interface.
3. (Optional) If desired, enable **Wildcard VLAN**.
4. Select **OK**.
5. Go to **Policy & Objects > IPv4 Virtual Wire Pair Policy**, select the virtual wire pair, and select **Create New**.
6. Select the direction that traffic is allowed to flow.
7. Configure the other firewall options as desired.
8. Select **OK**.
9. If necessary, create a second virtual wire pair policy to allow traffic to flow in the opposite direction.

If you have a USB-wan interface, it will not be included in the interface list when building a wired-pair.

Results

Traffic can now flow through the FortiGate using the virtual wire pair. For more information on this feature, see the [Networking](#) chapter.

Using the GUI

This section presents an introduction to the graphical user interface (GUI) on your FortiGate, also called the web-based manager.

The following topics are included in this section:

- [Connecting to the GUI](#)
- [Menus](#)
- [Dashboard](#)
- [Feature Visibility](#)
- [Tables](#)
- [Text strings](#)

Connecting to the GUI using a web browser

The graphical user interface is best displayed using a 1280 x 1024 resolution. Check the [FortiOS Release Notes](#) for information about browser compatibility.

In order to connect to the GUI using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access, with the IP address 192.168.1.99.

Browse to <https://192.168.1.99> and enter your username and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now be displayed in your browser.

If you wish to use a different interface to access the GUI, do the following:

1. Go to **Network > Interfaces** and edit the interface you wish to use for access. Take note of its assigned IP address.
2. Beside **Administrative Access**, select **HTTPS**, and any other protocol you require. You can also select **HTTP**, although this is not recommended as the connection will be less secure.
3. Select **OK**.
4. Browse to the IP address using your chosen protocol.

Results

The GUI will now be displayed in your browser.

Menus

If you believe your FortiGate model supports a menu that does not appear in the GUI as expected, go to **System > Feature Visibility** and ensure the feature is enabled. For more information, see ["Feature Visibility" on page 1](#).

The GUI contains the following main menus, which provide access to configuration options for most FortiOS features:

Dashboard	<p>The dashboard displays various widgets that display important system information and allow you to configure some system options.</p> <p>For more information, see "Dashboard" on page 1.</p>
Security Fabric	<p>Access the physical topology, logical topology, audit, and settings features of the Fortinet Security Fabric.</p> <p>For more information, see the Fortinet Security Fabric handbook.</p>
FortiView	<p>A collection of dashboards and logs that give insight into network traffic, showing which users are creating the most traffic, what sort of traffic it is, when the traffic occurs, and what kind of threat the traffic may pose to the network.</p> <p>For more information, see the FortiView handbook.</p>
Network	<p>Options for networking, including configuring system interfaces and routing options.</p> <p>For more information, see the Networking handbook.</p>
[[[Undefined variable FortiOSGUIVariables.Kee]]]	<p>Configure system settings, such as administrators, FortiGuard, and certificates.</p> <p>For more information, see the System Administration handbook.</p>
Policy & Objects	<p>Configure firewall policies, protocol options, and supporting content for policies, including schedules, firewall addresses, and traffic shapers.</p> <p>For more information, see the Firewall handbook.</p>
Security Profiles	<p>Configure your FortiGate's security features, including AntiVirus, Web Filtering, and Application Control.</p> <p>For more information, see the Security Profiles handbook.</p>
VPN	<p>Configure options for IPsec and SSL virtual private networks (VPNs).</p> <p>For more information, see the IPsec VPN and SSL VPN handbooks.</p>

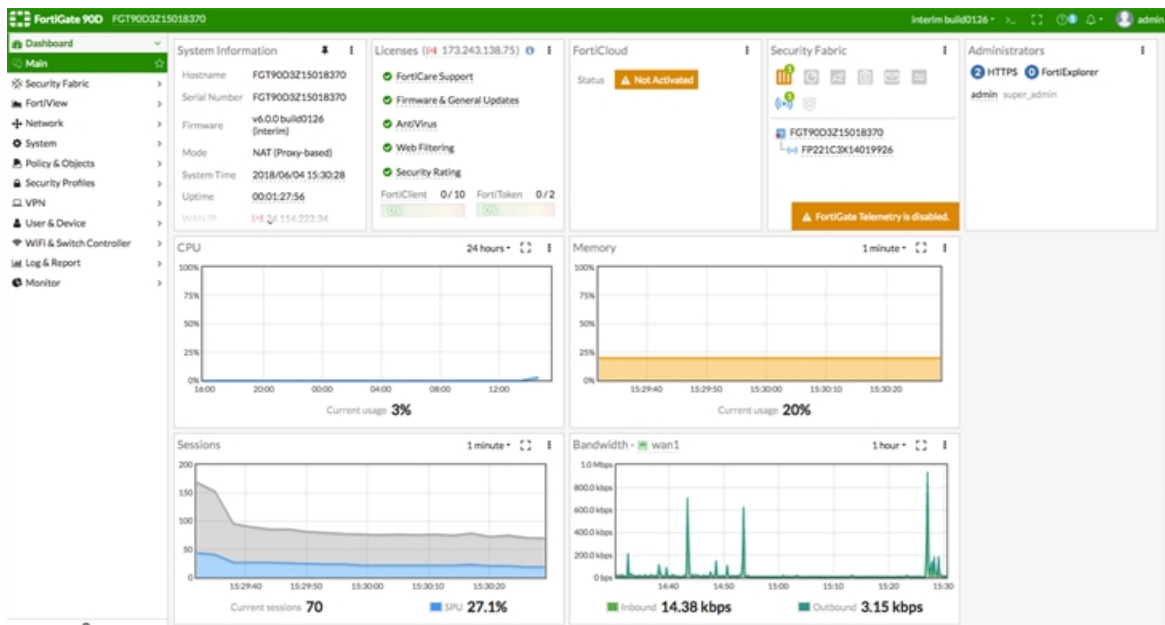

User & Device	Configure user accounts, groups, and authentication methods, including external authentication and single sign-on (SSO).
WiFi & Switch Controller	<p>Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units.</p> <p>On certain FortiGate models, this menu has additional features allowing for FortiSwitch units to be managed by the FortiGate.</p> <p>For more information, see the FortiWiFi and FortiAP Configuration Guide.</p>
Log & Report	<p>Configure logging and alert email as well as reports.</p> <p>For more information, see the Logging and Reporting handbook.</p>
Monitor	View a variety of monitors, including the Routing Monitor, VPN monitors for both IPsec and SSL, monitors relating to wireless networking, and more.

Dashboard

The FortiOS **Dashboard** consists of a Network Operations Center (NOC) view with a focus on alerts. Widgets are interactive. By clicking or hovering over most widgets, the user can see additional information or follow links to other pages.

The dashboard and its widgets include:

- Multiple dashboard support
- VDOM and global dashboards
- Widget resize control
- Notifications on the top header bar

The following widgets are displayed by default:

Widget	Description
System Information	The System Information widget lists information relevant to the FortiGate system, including hostname, serial number, and firmware.
Security Fabric	The Security Fabric widget displays a visual summary of many of the devices in the Security Fabric. For more information, see the Security Fabric handbook.
CPU	The real-time CPU usage is displayed for different timeframes.

Widget	Description
Licenses	<p>Hovering over the Licenses widget results in the display of status information (and, where applicable, database information) on the licenses for FortiCare Support, Firmware & General Updates, AntiVirus, Web Filtering, Security Rating, FortiClient, and FortiToken. Note that Mobile Malware is not a separate service in FortiOS 6.0.0. The Mobile Malware subscription is included with the AntiVirus subscription.</p> <p>Clicking in the Licenses widget provides you with links to other pages, such as System > FortiGuard or contract renewal pages.</p>
FortiCloud	This widget displays FortiCloud status and provides a link to activate FortiCloud.
Administrators	<p>This widget allows you to view:</p> <ul style="list-style-type: none"> • which administrators are logged in and how many sessions are active (a link directs you to a page displaying active administrator sessions) • all connected administrators and the protocols used by each
Memory	Real-time memory usage is displayed for different time frames. Hovering over any point on the graph displays percentage of memory used along with a timestamp.
Sessions	<p>Hovering over the Sessions widget allows you to view memory usage data over time. Click on the down arrow to change the timeframe displayed.</p> <p>Security processing unit, or SPU, percentage is displayed if your FortiGate includes an SPU. Likewise, nTurbo percentage is displayed if supported by your FortiGate. See the Hardware Acceleration chapter for details.</p>
Bandwidth	<p>Hover over the Bandwidth widget to display bandwidth usage data over time. Click on the down arrow to change the timeframe displayed. Bandwidth is displayed for both incoming and outgoing traffic.</p>
Virtual Machine	<p>The VM widget (shown by default in the dashboard of a FortiOS VM device) includes:</p> <ul style="list-style-type: none"> • License status and type • CPU allocation usage • License RAM usage • VMX license information (if the VM supports VMX) <p>If the VM license specifies 'unlimited' the progress bar is blank. If the VM is in evaluation mode, it is yellow (warning style) and the dashboard shows the number of evaluation days used.</p>

The following optional widgets are also available:

- FortiView
- Host Scan Summary

- Vulnerabilities Summary
- Botnet Activity
- HA Status
- Log Rate
- Session Rate
- Security Fabric Score
- Advanced Threat Protection Statistics
- Interface Bandwidth

Modifying dashboard widget titles

Dashboard widget titles can be modified so that widgets with different filters applied can be easily differentiated. The widget has a default title unless you set a new title.

Syntax

```
config system admin
  edit <name>
    config gui-dashboard
      config widget
        edit 9
          set type fortiview
          ...
          set title "test source by bytes"
        end
      end
    end
  end
```

Feature Visibility

Feature Visibility is used to control which features are visible in the GUI. This allows you to hide features that are not being used. Some features are also disabled by default and must be enabled in order to configure them through the GUI.

Feature Visibility only alters the visibility of these features, rather than their functionality. For example, disabling web filtering on the **Feature Visibility** page does not remove web filtering from the FortiGate, but removes the option of configuring web filtering from the GUI. Configuration options will still be available using the CLI.

Enabling/disabling features

Feature Visibility can be found at **System > Feature Visibility**. Ensure that all features you wish to configure in the GUI are turned on, and that features you wish to hide are turned off. When you have finished, select **Apply**.

Security feature presets

The main security features can be toggled individually, however six system presets (or **Feature Sets**) are available:

- **NGFW** should be chosen for networks that require application control and protection from external attacks.
- **ATP** should be chosen for networks that require protection from viruses and other external threats.
- **WF** should be chosen for networks that require web filtering.
- **NGFW + ATP** should be chosen for networks that require protection from external threats and attacks.
- **UTM** should be chosen for networks that require protection from external threats and wish to use security features that control network usage. This is the default setting.
- **Custom** should be chosen for networks that require customization of available features (including the ability to select all features).

Tables

Many of the GUI pages contain tables of information that you can filter to display specific information. Administrators with read and write access can define the filters.

Navigation

Some tables contain information and lists that span multiple pages. Navigation controls appear at the bottom of the page.

Filters

Filters are used to locate a specific set of information or content within multiple pages. These are especially useful in locating specific log entries. The specific filtering options vary, depending on the type of information in the log.

To create a filter, select **Add Filter** at the top of the page. A list of the available fields for filtering will be shown.

Column settings

Column settings are used to select the types of information displayed on a certain page. Some pages have large amounts of information available and not all content can be displayed on a single screen. Some pages may even contain content that is irrelevant to you. Using column settings, you can choose to display only relevant content.

To view configure column settings, right-click the header of a column and select the columns you wish to view and deselect any you wish to hide. After you have finished making your selections, click **Apply** (you may need to scroll down the list to do so).

Any changes that you make to the column settings are stored in the unit's configuration. To return columns to the default state for any given page, right-click any header and select **Reset Table**.

Copying objects

In tables containing configuration objects, such as the policy table found at **Policy & Objects > IPv4 Policy**, you have the option to copy an object. This allows you to create a copy of that object, which you can then configure as needed. You can also reverse copy a policy to change the direction of the traffic impacted by that policy.

To copy an object:

1. Select that object, then right-click to make a menu appear and select the **Copy** option.
2. Right-click the row in the table that is either above or below where you want the copied object to be placed, select the **Paste** option and indicate **Above** or **Below**.

Reverse cloning works much the same way. Instead of selecting **Copy**, select **Clone Reverse**.

Once the policy is copied, you must give it a name, configure as needed, and enable it.

Editing objects

Some tables allow you to edit parts of the configuration directly on the table itself. For example, security features can be added to an existing firewall policy from the policy list by clicking on the plus sign in the **Security Profiles** column and selecting the desired profiles.

If this option is not immediately available, check to see that the column is not hidden (see [Column settings](#)). Otherwise, you must select the object and open the policy by selecting the **Edit** option found at the top of the page.

Text strings

The configuration of a FortiGate is stored in the FortiOS configuration database. To change the configuration, you can use the GUI or CLI to add, delete, or change configuration settings. These changes are stored in the database as you make them. Individual settings in the configuration database can be text strings, numeric values, selections from a list of allowed options, or on/off (enable/disable) settings.

Entering text strings (names)

Text strings are used to name entities in the configuration. For example, the name of a firewall address, the name of an administrative user, and so on. You can enter any character in a FortiGate configuration text string, except the following characters that present cross-site scripting (XSS) vulnerabilities:

- “ (double quote)
- & (ampersand)
- ' (single quote)
- < (less than)
- > (greater than)

Most GUI text string fields make it easy to add an acceptable number of characters and prevent you from adding the XSS vulnerability characters.

There is a different character limitation for VDOM names and hostnames. The only valid characters are numbers (0-9), letters (a-z, A-Z), and special characters - (dash) and _ (underscore).

You can also use the `tree` command in the CLI to view the number of characters allowed in a name field. For example, firewall address names can contain up to 64 characters. When you add a firewall address to the GUI, you are limited to entering 64 characters in the firewall address name field. From the CLI you can enter the following `tree` command to confirm that the firewall address `name` field allows 64 characters.

```
config firewall address
  tree
  -- [address] --*name (64)
  |- uuid
  |- subnet
  |- type
  |- start-ip
  |- end-ip
  |- fqdn (256)
  |- country (3)
  |- cache-ttl (0,86400)
  |- wildcard
  |- comment
  |- visibility
  |- associated-interface (36)
  |- color (0,32)
  |- [tags] --*name (65)
  +- allow-routing
```

The `tree` command output also shows the number of characters allowed for other firewall address name settings. For example, the fully qualified domain name (`fqdn`) field can contain up to 256 characters.

Entering numeric values

Numeric values set various sizes, rates, addresses, and other numeric values (e.g. a static routing priority of 10, a port number of 8080, an IP address of 10.10.10.1). Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or, as in the case of MAC or IPv6 addresses, separated by colons (e.g. the MAC address 00:09:0F:B7:37:00). Most numeric values are standard base 10 numbers, but some fields, such as MAC addresses, require hexadecimal numbers.

Most GUI numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help text includes information about allowed numeric value ranges. Both the GUI and the CLI prevent you from entering invalid numbers.

Using the CLI

The command line interface (CLI) is an alternative configuration tool to the GUI or web-based manager. While the configuration of the GUI uses a point-and-click method, the CLI requires typing commands or uploading batches of commands from a text file, like a configuration script.

This section explains common CLI tasks that an administrator performs on a regular basis and includes the topics:

- [Connecting to the CLI](#)
- [Command syntax](#)
- [Sub-commands](#)
- [Permissions](#)
- [Tips](#)

Connecting to the CLI

You can access the CLI in three ways:

- [Locally with a console cable](#) — Connect your computer directly to the console port of your FortiGate. Local access is required in some cases:
 - If you are installing your FortiGate for the first time and it is not yet configured to connect to your network, you may only be able to connect to the CLI using a local serial console connection, unless you reconfigure your computer's network settings for a peer connection.
 - Restoring the firmware utilizes a boot interrupt. Network access to the CLI is not available until after the boot process has completed, making local CLI access the only viable option.
- [Through the network](#) — Connect your computer through any network interface attached to one of the network ports on your FortiGate. The network interface must have enabled Telnet or SSH administrative access if you connect using an SSH/Telnet client, or HTTP/HTTPS administrative access if you connect by accessing the **CLI Console** in the GUI. The CLI console can be accessed from the upper-right hand corner of the screen and appears as a slide-out window.
- [Locally with FortiExplorer for iOS](#) — Use the FortiExplorer app on your iOS device to configure, manage, and monitor your FortiGate.

Connecting to the CLI using a local console

Local console connections to the CLI are formed by directly connecting your management computer or console to the FortiGate unit, using its DB-9 or RJ-45 console port. To connect to the local console you need:

- A computer with an available serial communications (COM) port.
- The RJ-45-to-DB-9 or null modem cable included in your FortiGate package.
- Terminal emulation software such as HyperTerminal for Microsoft Windows.

The following procedure describes the connection using Microsoft HyperTerminal software; steps may vary with other terminal emulators.

To connect to the CLI using a local serial console connection

1. Using the null modem or RJ-45-to-DB-9 cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.
2. On your management computer, start HyperTerminal.
3. For the **Connection Description**, enter a **Name** for the connection, and select **OK**.
4. On the **Connect using** drop-down, select the communications (COM) port on your management computer you are using to connect to the FortiGate unit.
5. Select **OK**.
6. Select the following **Port** settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

7. Press **Enter** or **Return** on your keyboard to connect to the CLI.
8. Type a valid administrator account name (such as `admin`) and press **Enter**.
9. Type the password for that administrator account and press **Enter**. (In its default state, there is no password for the `admin` account.)

The CLI displays the following text:

```
Welcome!
Type ? to list available commands.
```

You can now enter CLI commands, including configuring access to the CLI through SSH or Telnet.

Enabling access to the CLI through the network (SSH or Telnet)

SSH or Telnet access to the CLI is accomplished by connecting your computer to the FortiGate unit using one of its RJ-45 network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH/Telnet client and you have access to the web-based manager, you can alternatively access the CLI through the network using the **CLI Console** widget in the web-based manager.

You must enable SSH and/or Telnet on the network interface associated with that physical network port. If your computer is not connected directly or through a switch, you must also configure the FortiGate unit with a static route to a router that can forward packets from the FortiGate unit to your computer. You can do this using either a local console connection or the web-based manager.

Requirements

- A computer with an available serial communications (COM) port and RJ-45 port
- Terminal emulation software such as HyperTerminal for Microsoft Windows

- The RJ-45-to-DB-9 or null modem cable included in your FortiGate package
- A network cable
- Prior configuration of the operating mode, network interface, and static route.

To enable SSH or Telnet access to the CLI using a local console connection

1. Using the network cable, connect the FortiGate unit's network port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate unit.
2. Note the number of the physical network port.
3. Using a local console connection, connect and log into the CLI.
4. Enter the following command:

```
config system interface
  edit <interface_str>
    set allowaccess <protocols_list>
  end
```

where:

- <interface_str> is the name of the network interface associated with the physical network port and containing its number, such as `port1`.
- <protocols_list> is the complete, space-delimited list of permitted administrative access protocols, such as `https ssh telnet`.

For example, to exclude HTTP, HTTPS, SNMP, and PING, and allow only SSH and Telnet administrative access on `port1`, enter the following:

```
config system interface
  edit port1
    set allowaccess ssh telnet
  end
```

5. To confirm the configuration, enter the command to display the network interface's settings.

```
show system interface <interface_str>
```

The CLI displays the settings, including the allowed administrative access protocols, for the network interfaces.

Connecting to the CLI using SSH

Once the FortiGate unit is configured to accept SSH connections, you can use an SSH client on your management computer to connect to the CLI.

Secure Shell (SSH) provides both secure authentication and secure communications to the CLI. FortiGate units support 3DES and Blowfish encryption algorithms for SSH.

Before you can connect to the CLI using SSH, you must first configure a network interface to accept SSH connections. The following procedure uses PuTTY. Steps may vary with other SSH clients.

To connect to the CLI using SSH

1. On your management computer, start an SSH client.
2. In **Host Name (or IP address)**, enter the IP address of a network interface on which you have enabled SSH administrative access.
3. Set a **Port** of 22.

4. For the **Connection type**, select **SSH**.

5. Select **Open**.

The SSH client connects to the FortiGate unit.

The SSH client may display a warning if this is the first time you are connecting to the FortiGate unit and its SSH key is not yet recognized by your SSH client, or if you have previously connected to the FortiGate unit but used a different IP address or SSH key. This is normal if your management computer is directly connected to the FortiGate unit with no network hosts between them.

6. Click **Yes** to verify the fingerprint and accept the FortiGate unit's SSH key. You will not be able to log in until you have accepted the key.
7. The CLI displays a login prompt.
8. Type a valid administrator account name (such as `admin`) and press **Enter**.
9. Type the password for this administrator account and press **Enter**.

The FortiGate unit displays a command prompt (its hostname followed by a #). You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

Connecting to the CLI using Telnet

Once the FortiGate unit is configured to accept Telnet connections, you can use a Telnet client on your management computer to connect to the CLI.

Telnet is not a secure access method. SSH should be used to access the CLI from the Internet or any other untrusted network.

Before you can connect to the CLI using Telnet, you must first configure a network interface to accept Telnet connections.

To connect to the CLI using Telnet

1. On your management computer, start a Telnet client.
2. Connect to a FortiGate network interface on which you have enabled Telnet.
3. Type a valid administrator account name (such as `admin`) and press **Enter**.
4. Type the password for this administrator account and press **Enter**.

The FortiGate unit displays a command prompt (its hostname followed by a #). You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

CLI-only features

As you can see in the [Feature / Platform Matrix](#), the entry level models have a number of features that are only available using the CLI, rather than appearing in the GUI.

You can open the CLI console so that it automatically opens to the object you wish to configure. For example, to edit a firewall policy, right-click on the policy in the policy list (**Policy & Objects > IPv4 Policy**) and select **Edit in CLI**. The CLI console will appear, with the commands to access this part of the configuration added automatically.

Once you have access to the CLI, you can enter instructions for specific tasks that can be found throughout the FortiOS Handbook. Options are also available at the top of the CLI Console to **Clear console**, **Download**, and **Copy to clipboard**.

Refer to the [CLI Reference](#) for a list of the available commands.

Command syntax

When entering a command, the CLI console requires that you use valid syntax and conform to expected input constraints. It will reject invalid commands.

Fortinet documentation uses the conventions below to describe valid command syntax.

Terminology

Each command line consists of a command word that is usually followed by configuration data or other specific item that the command uses or affects.

To describe the function of each word in the command line, especially if that nature has changed between firmware versions, Fortinet uses terms with the following definitions.

Command syntax terminology

- **Command** — A word that begins the command line and indicates an action that the FortiGate should perform on a part of the configuration or host on the network, such as `config` or `execute`. Together with other words, such as fields or values, that end when you press the **Enter** key, it forms a command line. Exceptions include multiline command lines, which can be entered using an escape sequence.
Valid command lines must be unambiguous if abbreviated. Optional words or other command line permutations are indicated by syntax notation.
- **Sub-command** — A `config` sub-command that is available only when nested within the scope of another command. After entering a command, its applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into another sub-command. Indentation is used to indicate levels of nested commands.
Not all top-level commands have sub-commands. Available sub-commands vary by their containing scope.
- **Object** — A part of the configuration that contains tables and /or fields. Valid command lines must be specific enough to indicate an individual object.
- **Table** — A set of fields that is one of possibly multiple similar sets which each have a name or number, such as an administrator account, policy, or network interface. These named or numbered sets are sometimes referenced by other parts of the configuration that use them.
- **Field** — The name of a setting, such as `ip` or `hostname`. Fields in some tables must be configured with values. Failure to configure a required field will result in an invalid object configuration error message, and the FortiGate will discard the invalid table.
- **Value** — A number, letter, IP address, or other type of input that is usually your configuration setting held by a field. Some commands, however, require multiple input values which may not be named but are simply entered in sequential order in the same command line. Valid input types are indicated by constraint notation.
- **Option** — A kind of value that must be one or more words from of a fixed set of options.

Indentation

Indentation indicates levels of nested commands, which indicate what other sub-commands are available from within the scope. The “`next`” and “`end`” lines are used to maintain a hierarchy and flow to CLI commands, especially helping to distinguish those commands with extensive sub-commands.

The “`next`” line is entered at the same indentation-level as the previous “`edit`”, to mark where you would like to finish that table entry and move on to the next table entry; doing so will not mean that you have “left” that sub-command.

next

Below is an example command, with a sub-command of `entries`:

```
config dlp filepattern
edit <1>
    set name <name>
    set comment [comment]
    config entries
        edit <2>
            set filter-type {pattern | type}
        next
    ←
```

After entering settings for <2> and entering `next`, the <2> table entry has been saved, and you be set back one level of indentation so you can continue to create more `entries` (if you wish).

This hierarchy is best indicated in the CLI console, as the example below is what displays in the console after entering `next`:

```
FGT60E1Q23456789 (entries) #
```

To go-back up an indentation-level from this point on (i.e. to finish configuring the `entries` sub-command), you **cannot** enter `next`; you must enter `end`.

end

Below is the same command and sub-command, except `end` has been entered instead of `next` after the sub-command:

```
config dlp filepattern
edit <1>
    set name <name>
    set comment [comment]
    config entries
        edit <2>
            set filter-type {pattern | type}
        end
    ←
```

Entering `end` will save the <2> table entry, but bring you out of the sub-command entirely; in this example, you would enter this when you don't wish to continue creating new `entries`.

Again, your hierarchy is best indicated by the CLI console. Below is what displays in the console after entering `end`:

```
FGT60E1Q23456789 (1) #
```

Notation

Brackets, braces, and pipes are used to denote valid permutations of the syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

All syntax uses the following conventions:

Convention	Description
Square brackets []	<p>An optional word or series of words. For example:</p> <pre>[verbose {1 2 3}]</pre> <p>indicates that you may either omit or type both the word <code>verbose</code> and its accompanying option/s, such as <code>verbose 3</code>.</p> <p>See Optional values and ranges below for more information.</p>
Curly braces { }	<p>A word or series of words that is constrained to a set of options delimited by either vertical bars or spaces. You must enter at least one of the options, unless the set of options is surrounded by square brackets [].</p>
Mutually exclusive options - delimited by vertical bars	<p>Both mutually and non-mutually exclusive commands will use curly braces, as they provide multiple options, however mutually exclusive commands will divide each option with a pipe. This indicates that you are permitted to enter one option or the other:</p> <pre>{enable disable}</pre>
Non-mutually exclusive options - delimited by spaces	<p>Non-mutually exclusive commands do not use pipes to divide their options. In those circumstances, multiple options can be entered at once, as long as they are entered with a space separating each option:</p> <pre>{http https ping snmp ssh telnet}</pre>

Convention	Description
Angle brackets < >	<p>A word constrained by data type. The angled brackets contain a descriptive name followed by an underscore (_) and suffix that indicates the valid data type. For example, <retries_int>, indicates that you should enter a number of retries as an integer.</p> <p>Data types include:</p> <ul style="list-style-type: none"> • <xxx_name>: A name referring to another part of the configuration, such as <code>policy_A</code>. • <xxx_index>: An index number referring to another part of the configuration, such as 0 for the first static route. • <xxx_pattern>: A regular expression or word with wild cards that matches possible variations, such as <code>*@example.com</code> to match all email addresses ending in <code>@example.com</code>. • <xxx_fqdn>: A fully qualified domain name (FQDN), such as <code>mail.example.com</code>. • <xxx_email>: An email address, such as <code>admin@example.com</code>. • <xxx_ipv4>: An IPv4 address, such as <code>192.168.1.99</code>. • <xxx_v4mask>: A dotted decimal IPv4 netmask, such as <code>255.255.255.0</code>. • <xxx_ipv4mask>: A dotted decimal IPv4 address and netmask separated by a space, such as <code>192.168.1.99 255.255.255.0</code>. • <xxx_ipv4/mask>: A dotted decimal IPv4 address and CIDR-notation netmask separated by a slash, such as <code>192.168.1.1/24</code> • <xxx_ipv4range> : A hyphen (-)-delimited inclusive range of IPv4 addresses, such as <code>192.168.1.1-192.168.1.255</code>. • <xxx_ipv6>: A colon (:)-delimited hexadecimal IPv6 address, such as <code>3f2e:6a8b:78a3:0d82:1725:6a2f:0370:6234</code>. • <xxx_v6mask>: An IPv6 netmask, such as <code>/96</code>. • <xxx_ipv6mask>: A dotted decimal IPv6 address and netmask separated by a space. • <xxx_str>: A string of characters that is not another data type, such as <code>P@ssw0rd</code>. Strings containing spaces or special characters must be surrounded in quotes or use escape sequences. • <xxx_int>: An integer number that represents a metric, <code>minutes_int</code> for the number of minutes.

Optional values and ranges

Any field that is optional will use square-brackets, such as `set comment`. This is because it doesn't matter whether it's set or not. The overall config command will still successfully be taken.

Another example of where square-brackets would be used is to show that multiple options can be set, even intermixed with ranges. The example below shows a field that can be set to either a specific value or range, or multiple instances:

```
config firewall service custom
  set iprange <range1> [<range2> <range3> ...]
```

end

Sub-commands

Each command line consists of a command word that is usually followed by configuration data or other specific item that the command uses or affects:

```
get system admin
```

Sub-commands are available from within the scope of some commands. When you enter a sub-command level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin) #
```

Applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into another sub-command.

For example, the `edit` sub-command is available only within a command that affects tables; the `next` sub-command is available only from within the `edit` sub-command:

```
config system interface
  edit port1
    set status up
  next
end
```

Sub-command scope is indicated by indentation.

Available sub-commands vary by command. From a command prompt within `config`, two types of sub-commands might become available:

- commands affecting fields
- commands affecting tables

Commands for tables

clone <table>

Clone (or make a copy of) a table from the current object.

For example, in `config firewall policy`, you could enter the following command to clone security policy 27 to create security policy 30:

```
clone 27 to 30
```

In `config antivirus profile`, you could enter the following command to clone an antivirus profile named `av_pro_1` to create a new antivirus profile named `av_pro_2`:

```
clone av_pro_1 to av_pro_2
```

`clone` may not be available for all tables.

delete <table>

Remove a table from the current object.

For example, in `config system admin`, you could delete an administrator account named `newadmin` by typing `delete newadmin` and pressing Enter. This deletes `newadmin` and all its fields, such as `newadmin's first-name` and `email-address`.

`delete` is only available within objects containing tables.

edit <table>

Create or edit a table in the current object.

For example, in `config system admin`:

- edit the settings for the default `admin` administrator account by typing `edit admin`.
- add a new administrator account with the name `newadmin` and edit `newadmin's` settings by typing `edit newadmin`.

`edit` is an interactive sub-command: further sub-commands are available from within `edit`.

`edit` changes the prompt to reflect the table you are currently editing.

`edit` is only available within objects containing tables.

In objects such as security policies, `<table>` is a sequence number. To create a new entry without the risk of overwriting an existing one, enter `edit 0`. The CLI initially confirms the creation of entry 0, but assigns the next unused number after you finish editing and enter `end`.

end

Save the changes to the current object and exit the `config` command. This returns you to the top-level command prompt.

get

List the configuration of the current object or table.

- In objects, `get` lists the table names (if present), or fields and their values.
- In a table, `get` lists the fields and their values.

For more information on `get` commands, see the [CLI Reference](#).

purge

Remove all tables in the current object.

For example, in `config user local`, you could type `get` to see the list of user names, then type `purge` and then `y` to confirm that you want to delete all users.

`purge` is only available for objects containing tables.

Caution: Back up the FortiGate before performing a `purge`. `purge` cannot be undone. To restore purged tables, the configuration must be restored from a backup.

Caution: Do not purge `system interface` or `system admin` tables. `purge` does not provide default tables. This can result in being unable to connect or log in, requiring the FortiGate to be formatted and restored.

rename <table> to <table>

Rename a table.

For example, in `config system admin`, you could rename `admin3` to `fwadmin` by typing `rename admin3 to fwadmin`.

`rename` is only available within objects containing tables.

show

Display changes to the default configuration. Changes are listed in the form of configuration commands.

Example of table commands

From within the `system admin` object, you might enter:

```
edit admin_1
```

The CLI acknowledges the new table, and changes the command prompt to show that you are now within the `admin_1` table:

```
new entry 'admin_1' added
(admin_1) #
```

Commands for fields**abort**

Exit both the `edit` and/or `config` commands without saving the fields.

append

Add an option to an existing list.

end

Save the changes made to the current table or object fields, and exit the `config` command (to exit without saving, use `abort` instead).

get

List the configuration of the current object or table.

- In objects, `get` lists the table names (if present), or fields and their values.
- In a table, `get` lists the fields and their values.

move	Move an object within a list, when list order is important. For example, rearranging security policies within the policy list.
next	<p>Save the changes you have made in the current table's fields, and exit the <code>edit</code> command to the object prompt (to save and exit completely to the root prompt, use <code>end</code> instead).</p> <p><code>next</code> is useful when you want to create or edit several tables in the same object, without leaving and re-entering the <code>config</code> command each time.</p> <p><code>next</code> is only available from a table prompt; it is not available from an object prompt.</p>
select	<p>Clear all options except for those specified.</p> <p>For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command <code>select member B</code>.</p>
set <field> <value>	<p>Set a field's value.</p> <p>For example, in <code>config system admin</code>, after typing <code>edit admin</code>, you could type <code>set password newpass</code> to change the password of the <code>admin</code> administrator to <code>newpass</code>.</p> <p>Note: When using <code>set</code> to change a field containing a space-delimited list, type the whole new list. For example, <code>set <field> <new-value></code> will replace the list with the <code><new-value></code> rather than appending <code><new-value></code> to the list.</p>
show	Display changes to the default configuration. Changes are listed in the form of configuration commands.
unselect	Remove an option from an existing list.
unset <field>	<p>Reset the table or object's fields to default values.</p> <p>For example, in <code>config system admin</code>, after typing <code>edit admin</code>, typing <code>unset password</code> resets the password of the <code>admin</code> administrator account to the default (in this case, no password).</p>

Example of field commands

To assign the value `my1stExamplePassword` to the `password` field, enter the following command from within the `admin_1` table:

```
set password my1stExamplePassword
```

Next, to save the changes and edit the next administrator's table, enter the `next` command.

Permissions

Access profiles control which CLI commands an administrator account can access. Access profiles assign either read, write, or no access to each area of FortiOS. To view configurations, you must have read access. To make changes, you must have write access. So, depending on the account used to log in to the FortiGate unit, you may not have complete access to all CLI commands. For complete access to all commands, you must log in with the administrator account named `admin`.

Unlike other administrator accounts, the `admin` account exists by default and cannot be deleted. The `admin` account is similar to a root administrator account that always has full permission to view and change all FortiGate configuration options, including viewing and changing all other administrator accounts. Its name and permissions cannot be changed. It is the only administrator account that can reset another administrator's password without being required to enter that administrator's existing password.

Set a strong password for the `admin` account, and change the password regularly. By default, this administrator account has no password. Failure to maintain the password of the `admin` account could compromise the security of your FortiGate.

Tips

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

Help

To display brief help during command entry, press the question mark (?) key.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Type a word or part of a word, then press the question mark (?) key to display a list of valid word completions or subsequent words, and to display a description of each.

Shortcuts and key commands

Keys	Action
?	List valid word completions or subsequent words. If multiple words could complete your entry, display all possible completions with helpful descriptions of each.
Tab	Complete the word with the next available match. Press the Tab key multiple times to cycle through available matches.
Up arrow, or Ctrl + P	Recall the previous command. Command memory is limited to the current session.
Down arrow, or Ctrl + N	Recall the next command.
Left or Right arrow	Move the cursor left or right within the command line.
Ctrl + A	Move the cursor to the beginning of the command line.
Ctrl + E	Move the cursor to the end of the command line.
Ctrl + B	Move the cursor backwards one word.
Ctrl + F	Move the cursor forwards one word.
Ctrl + D	Delete the current character.

Keys	Action
Ctrl + C	<p>Abort current interactive commands, such as when entering multiple lines.</p> <p>If you are not currently within an interactive command such as <code>config</code> or <code>edit</code>, this closes the CLI connection.</p>
\ then Enter	<p>Continue typing a command on the next line for a multiline command.</p> <p>For each line that you want to continue, terminate it with a backslash (\). To complete the command line, terminate it by pressing the spacebar and then the Enter key, without an immediately preceding backslash.</p>

Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy stat`.

Adding and removing options from lists

When adding options to a list, such as a user group, using the `set` command will remove the previous configuration. For example, if you wish to add user D to a user group that already contains members A, B, and C, the command would need to be `set member A B C D`. If only `set member D` was used, then all former members would be removed from the group.

However, there are additional commands which can be used instead of `set` for changing options in a list.

Additional commands for lists

append	<p>Add an option to an existing list.</p> <p>For example, <code>append member</code> would add user D to a user group while all previous group members are retained</p>
select	<p>Clear all options except for those specified.</p> <p>For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command <code>select member B</code>.</p>
unselect	<p>Remove an option from an existing list.</p> <p>For example, <code>unselect member A</code> would remove member A from a group while all previous group members are retained.</p>

Environment variables

The CLI supports the following environment variables. Variable names are case-sensitive.

Environment variables

\$USERFROM	The management access type (<code>ssh</code> , <code>telnet</code> , <code>jsconsole</code> for the CLI Console widget in the web-based manager, and so on) and the IP address of the administrator that configured the item.
\$USERNAME	The account name of the administrator that configured the item.
\$SerialNum	The serial number of the FortiGate unit.

For example, the FortiGate unit's host name can be set to its serial number:

```
config system global
    set hostname $SerialNum
end
```

Special characters

The following special characters, also known as reserved characters, are not permitted in most CLI fields:

< > () # ' “

You may be able to enter special characters as part of a string's value by using a special command, enclosing it in quotes, or preceding it with an escape sequence — in this case, a backslash (\) character.

In other cases, different keystrokes are required to input a special character. If you need to enter **?** as part of config, you first need to input **CTRL-V**. If you enter **?** without first using **CTRL-V**, the question mark has a different meaning in the CLI; it will show available command options in that section.

For example, if you enter **?** without **CTRL-V**:

```
edit "*.xe
token line: Unmatched double quote.
```

If you enter **?** with **CTRL-V**:

```
edit "*.xe?"
new entry '*.xe?' added
```

Entering special characters

Character	Keys
?	Ctrl + V then ?
Tab	Ctrl + V then Tab

Character	Keys
Space (to be interpreted as part of a string value, not to end the string)	Enclose the string in quotation marks: "Security Administrator". Enclose the string in single quotes: 'Security Administrator'. Precede the space with a backslash: Security\ Administrator.
'	\'
(to be interpreted as part of a string value, not to end the string)	
"	\"
(to be interpreted as part of a string value, not to end the string)	
\	\\

Using grep to filter get and show command output

In many cases, the `get` and `show` (and `diagnose`) commands may produce a large amount of output. If you are looking for specific information in a large `get` or `show` command output, you can use the `grep` command to filter the output to only display what you are looking for. The `grep` command is based on the standard UNIX `grep`, used for searching text output based on regular expressions.

Use the following command to display the MAC address of the FortiGate unit internal interface:

```
get hardware nic internal | grep Current_HWaddr
Current_HWaddr           00:09:0f:cb:c2:75
```

Use the following command to display all TCP sessions in the session list and include the session list line number in the output:

```
get system session list | grep -n tcp
```

Use the following command to display all lines in HTTP replacement message commands that contain URL (upper or lower case):

```
show system replacemsg http | grep -i url
```

There are three additional options that can be applied to `grep`:

```
-A <num> After
-B <num> Before
-C <num> Context
```

The option `-f` is also available to support contextual output, in order to show the complete configuration. The following example shows the difference in output when `-f` option is used versus when it is not.

Using -f:

```

show | grep -f ldap-group1
config user group
  edit "ldap-group1"
    set member "pc40-LDAP"
  next
end
config firewall policy
  edit 2
    set srcintf "port31"
    set dstintf "port32"
    set srcaddr "all"
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule "always"
        set groups "ldap-group1"
        set dstaddr "all"
        set service "ALL"
      next
    end
  next
end

```

Without using -f:

```

show | grep ldap-group1
edit "ldap-group1"
  set groups "ldap-group1"

```

Language support and regular expressions

Characters such as ñ, é, symbols, and ideographs are sometimes acceptable input. Support varies by the nature of the item being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values may be input using your language of choice. To use other languages in those cases, you must use the correct encoding.

Input is stored using Unicode UTF-8 encoding but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, your configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using another encoding, or if an HTTP client sends a request in an encoding other than UTF-8, matches may not be what you expect.

For example, with Shift-JIS, backslashes (\) could be inadvertently interpreted as the symbol for the Japanese yen (¥) and vice versa. A regular expression intended to match HTTP requests containing money values with a yen symbol therefore may not work if the symbol is entered using the wrong encoding.

For best results, you should:

- use UTF-8 encoding, or
- use only the characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are also encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS and other encodings, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary by the client's operating system or input language. If you cannot predict the client's encoding, you may only be able to match any parts of the request that are in English, because regardless of the encoding, the values for English characters tend to be encoded identically. For example, English words may be legible regardless of interpreting a web page as either ISO 8859-1 or as GB2312, whereas simplified Chinese characters might only be legible if the page is interpreted as GB2312.

If you configure your FortiGate unit using other encodings, you may need to switch language settings on your management computer, including for your web browser or Telnet/SSH client. For instructions on how to configure your management computer's operating system language, locale, or input method, see its documentation.

If you choose to configure parts of the FortiGate unit using non-ASCII characters, verify that all systems interacting with the FortiGate unit also support the same encodings. You should also use the same encoding throughout the configuration if possible in order to avoid needing to switch the language settings of the web-based manager and your web browser or Telnet/SSH client while you work.

Similarly to input, your web browser or CLI client should normally interpret display output as encoded using UTF-8. If it does not, your configured items may not display correctly in the GUI or CLI. Exceptions include items such as regular expressions that you may have configured using other encodings in order to match the encoding of HTTP requests that the FortiGate unit receives.

To enter non-ASCII characters in the CLI console:

1. On your management computer, start your web browser and go to the URL for the FortiGate unit's GUI.
2. Configure your web browser to interpret the page as UTF-8 encoded.
3. Log in to the FortiGate unit.
4. Open the CLI Console from the upper right-hand corner.
5. In the title bar of the **CLI Console** widget, click **Edit** (the pencil icon).
6. Enable **Use external command input box** and select **OK**.
7. The **Command** field appears below the usual input and display area of the **CLI Console**.
8. Type a command in this field and press **Enter**.

In the display area, the **CLI Console** widget displays your previous command interpreted into its character code equivalent, such as:

```
edit \743\601\613\743\601\652
```

and the command's output.

To enter non-ASCII characters in a Telnet/SSH client

1. On your management computer, start your Telnet or SSH client.
2. Configure your Telnet or SSH client to send and receive characters using UTF-8 encoding.
Support for sending and receiving international characters varies by each Telnet/SSH client. Consult the documentation for your Telnet/SSH client.

3. Log in to the FortiGate unit.
4. At the command prompt, type your command and press **Enter**.

You may need to surround words that use encoded characters with single quotes (').

Depending on your Telnet/SSH client's support for your language's input methods and for sending international characters, you may need to interpret them into character codes before pressing Enter.

For example, you might need to enter:

```
edit '\743\601\613\743\601\652'
```

5. The CLI displays your previous command and its output.

Screen paging

You can configure the CLI to pause after displaying each page's worth of text when displaying multiple pages of output. When the display pauses, the last line displays `--More--`. You can then either:

- press the **spacebar** to display the next page.
- type **q** to truncate the output and return to the command prompt.

This may be useful when displaying lengthy output, such as the list of possible matching commands for command completion, or a long list of settings. Rather than scrolling through or possibly exceeding the buffer of your terminal emulator, you can simply display one page at a time.

To configure the CLI Console to pause display when the screen is full:

```
config system console
  set output more
end
```

Baud rate

You can change the default baud rate of the local console connection.

To change the baud rate enter the following commands:

```
config system console
  set baudrate {9600 | 19200 | 38400 | 57600 | 115200}
end
```

Editing the configuration file on an external host

You can edit the FortiGate configuration on an external host by first backing up the configuration file to a TFTP server. Then edit the configuration file and restore it to the FortiGate unit.

Editing the configuration on an external host can be timesaving if you have many changes to make, especially if your plain text editor provides advanced features such as batch changes.

To edit the configuration on your computer:

1. Use `execute backup` to download the configuration file to a TFTP server, such as your management computer.
2. Edit the configuration file using a plain text editor that supports Unix-style line endings.

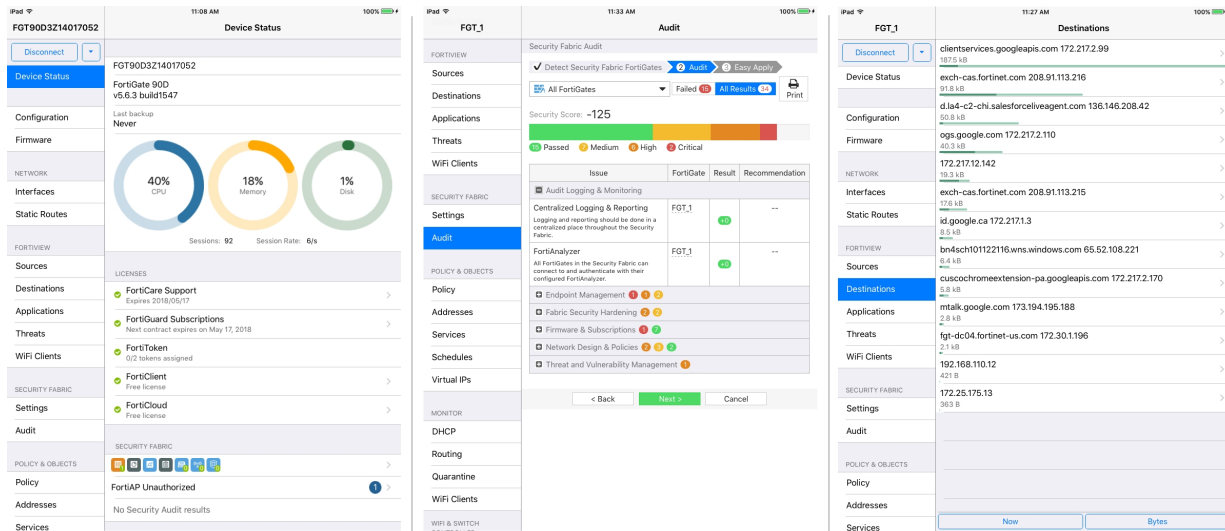

Do not edit the first line. The first line(s) of the configuration file (preceded by a # character) contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate unit will reject the configuration file when you attempt to restore it.

3. Use `execute restore` to upload the modified configuration file back to your FortiGate.

The FortiGate downloads the configuration file and checks that the model information is correct. If it is correct, the FortiGate unit loads the configuration file and checks each command for errors. If a command is invalid, the FortiGate unit ignores the command. If the configuration file is valid, the FortiGate unit restarts and loads the new configuration.

FortiExplorer for iOS

FortiExplorer for iOS is a user-friendly application that helps you to quickly and easily configure, manage, and monitor FortiGate appliances using an iOS device. FortiExplorer lets you rapidly provision, deploy, and monitor Security Fabric components including FortiGate, FortiWiFi, and FortiAP devices.

FortiExplorer for iOS requires iOS 9.3 or later and is compatible with iPhone, iPad, and iPod Touch. It is supported by FortiOS 5.6+ and is [only available on the App Store](#) for iOS devices.

Advanced features are available with the purchase of FortiExplorer Pro. Paid features include the ability to add more than two devices and the ability to download firmware images from FortiCare.

Up to six members can use this app with 'Family Sharing' enabled in the App Store.

Getting started with FortiExplorer

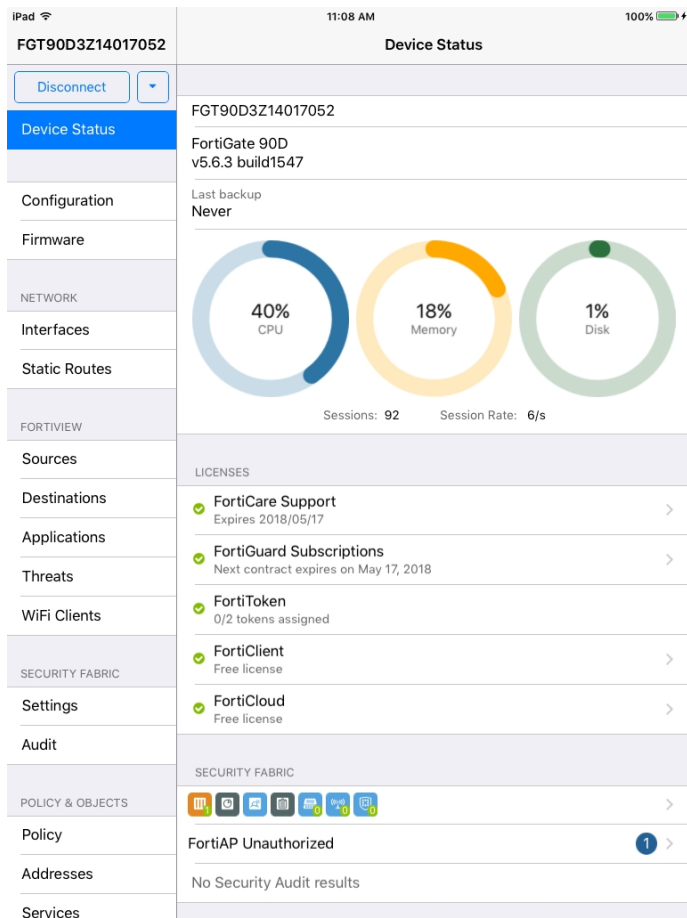

If your FortiGate is accessible on the wireless network, you can connect to it using FortiExplorer provided that your iOS device is on the same network (see [Connecting FortiExplorer to a FortiGate via WiFi](#)). Otherwise, you will need to physically connect your iOS device to the FortiGate using a USB cable (see below).

Connecting FortiExplorer to a FortiGate via USB

For the purpose of this document, we assume that you are just getting started; you do not have access to the FortiGate over the wireless network, and the FortiGate is in its factory configuration.

1. Connect your iOS device to your FortiGate's USB management port.
If prompted on your iOS device, **Trust** this 'computer'.
2. Open the FortiExplorer app and select your FortiGate from the list under **USB Attached Device**.
3. On the **Login** screen, select **USB**.
4. Enter the default **Username** (`admin`) and leave the **Password** field blank.
5. You can opt to **Remember Password**. Tap **Done** when you are ready.

FortiExplorer opens the FortiGate management interface to the **Device Status** page:

6. Go to **Network > Interfaces** and configure the WAN interface(s).
 In the example, the **wan1** interface **Address** mode is set to **DHCP** by default. Set it to **Manual** and enter its **Address**, **Netmask**, and **Default Gateway**, and then **Apply** your changes.

7. (Optional) Configure **Administrative Access** to allow **HTTP** and **HTTPS** access.
 This will allow administrators to access the FortiGate web-based manager using a web browser.

8. Go to **Network > Interfaces** and configure the local network (internal) interface. Set the **Address** mode as before and configure **Administrative Access** if desired.
9. Configure a **DHCP Server** for the internal network subnet.

Return to the internal interface using the button at the top of the screen.

10. Go to **Network > Static Routes** and configure the static route to the gateway.

11. Go to **Policy & Objects > Policy** and edit the Internet access policy. As a best practice, provide a **Name** for the policy, enable the desired **Security Profiles**, and configure **Logging Options**. Select **OK** to finalize.

Running a Security Fabric Rating

The FortiGate is now configured in a very basic state. Once you've configured the other potential elements of your network, such as other **Interfaces**, **Schedules**, or **Managed FortiAPs**, it is recommended that you run a **Security Fabric Rating** to identify potential vulnerabilities and highlight best practices that could be used to improve your network's overall security and performance.

Go to **Security Fabric > Security Rating** and follow the steps to determine a **Security Score** for the selected device(s). The results should identify issues ranging from Medium to Critical importance, and may provide recommended actions where possible.

Connecting FortiExplorer to a FortiGate via WiFi

If your FortiGate is accessible on the wireless network, you can connect to it using FortiExplorer provided that your iOS device is on the same network. Assuming this is the case:

1. Open the FortiExplorer app and select **Add** from the **Devices** page.
2. Enter the **Host** information and appropriate **Username** and **Password** credentials. If necessary, change the default **Port** number, and opt to **Remember Password**.

The screenshot shows the FortiExplorer app login screen. At the top, there are buttons for 'Cancel', 'Login', and 'Done'. Below these are input fields for 'Host' (172.25.176.56), 'Port' (443), 'Username' (admin), and 'Password'. There is also a 'Remember Password' toggle switch.

3. If the FortiGate device identity cannot be verified, click **Connect** at the prompt. FortiExplorer opens the FortiGate management interface to the **Device Status** page.

Upgrading to FortiExplorer Pro

Paid features provided with the purchase of FortiExplorer Pro include the ability to add more than two devices and the ability to download firmware images from FortiCare.

- To upgrade to FortiExplorer Pro, open the FortiExplorer app, go to **Settings** and select **Upgrade to FortiExplorer Pro**. Follow the on-screen prompts.

LED specifications

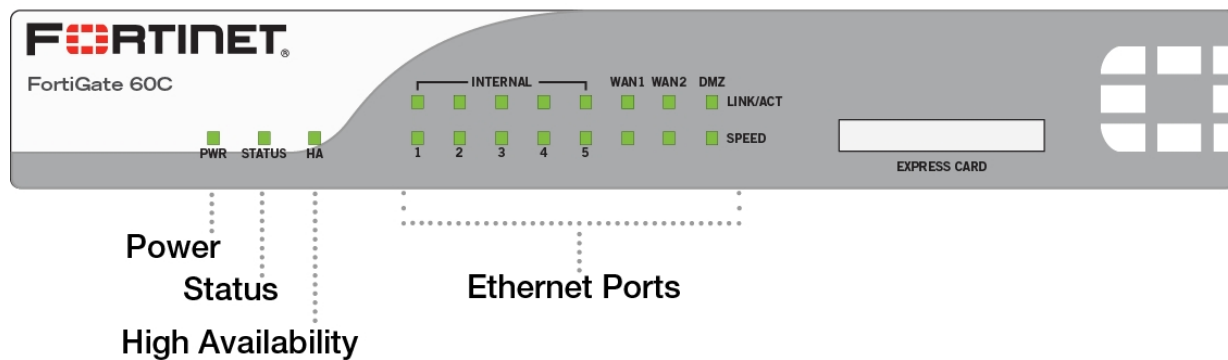

The following section includes information regarding FortiGate LED status indicators.

- [Sample FortiGate faceplates](#)
- [LED status codes](#)
- [About alarm levels](#)
- [LED status codes for ports](#)

Sample FortiGate faceplates

The faceplates indicate where the LEDs are typically found on desktop and mid-range FortiGate models.

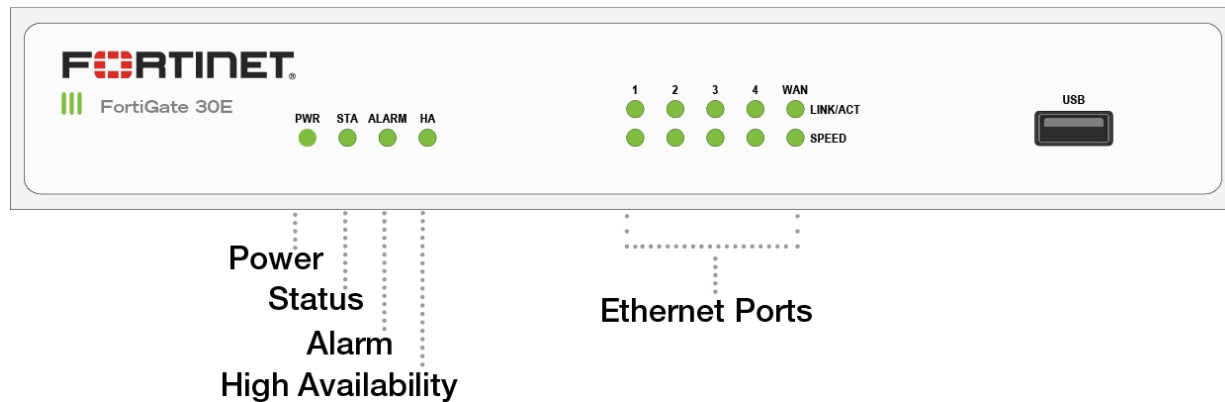

FortiGate 60C

FortiGate 100D

FortiGate 30E

LED status codes

LABEL	STATE	MEANING
PWR	Green	Power is On.
	Off	Power is Off.
STA	Green	Normal status.
	Flashing Green	Booting Up. If the FortiGate has a reset button, Flashing Green also means that the reset button was used.
	Red	The FortiGate has a critical alarm (see About Alarm Levels).
ALARM	Off	No alarms or the FortiGate has a minor alarm.
	Amber	The FortiGate has a major alarm.
	Red	The FortiGate has a critical alarm. The status LED will also be red.
		More information at About Alarm Levels .
HA	Green	FortiGate is operating in an FGCP HA cluster.
	Red	A failover has occurred.
	Off	HA not configured.
		Failover operation feature not available in all units.

LABEL	STATE	MEANING
WIFI	Green	Wireless port is active.
	Flashing Green	Wireless interface is transmitting and receiving data.
	Off	Wireless interface is down.

About alarm levels

Minor, major, and critical alarms are defined based on IPMI, ATCA, and Telco standards for naming alarms.

- A minor alarm (also called an IPMI non-critical (NC) alarm) indicates a temperature or a power level outside of the normal operating range that is not considered a problem. In the case of a minor temperature alarm, the system could respond by increasing fan speed. A non-critical threshold can be an upper non-critical (UNC) threshold (for example, a high temperature or a high power level) or a lower non-critical (LNC) threshold (for example, a low power level). The LEDs do not indicate minor alarms since user intervention is not required.
- A major alarm (also called an IPMI critical or critical recoverable (CR) alarm) indicates that the system itself cannot correct the cause for the alarm and that intervention is required. For example, the cooling system cannot provide enough cooling to reduce the temperature. It could also mean that conditions (e.g. temperature) are approaching the outside limit of the allowed operating range. A critical threshold can also be an upper critical (UC) threshold (e.g. a high temperature or a high power level) or a lower critical (LC) threshold (e.g. a low power level).
- A critical alarm (also called an IPMI non-recoverable (NR) alarm) indicates detection of a temperature or power level that is outside of the allowed operating range and could potentially cause physical damage.

LED status codes for ports

TYPE OF PORT	STATE	MEANING
Ethernet Ports Link / Activity	Green	Connected.
	Flashing Green	Transmitting and receiving data.
	Off	No link established.
		On FortiGate models with front-facing ports, this LED is to the left of the port. On FortiGate models with ports at the back of the device, this LED is in the upper row.
SFP Ports	Green	Connected.
	Flashing Green	Transmitting and receiving data.
	Off	No link established.

TYPE OF PORT	STATE	MEANING
Ethernet Ports Speed	Green	Connected at 1Gbps.
	Amber	Connected at 100Mbps.
	Off	Not connected or connected at 10Mbps.
		On FortiGate models with front-facing ports, this LED is to the right of the port. On FortiGate models with ports at the back of the device, this LED is in the lower row.

Inspection mode

To control your FortiGate's security profile inspection mode in FortiOS 6.0, you can select **Flow-based** or **Proxy** inspection modes from **System > Settings**. Having control over flow and proxy mode is helpful if you want to ensure that only flow inspection mode is used.

In most cases proxy mode is preferred because more security profile features are available along with more configuration options for these individual features. Some implementations, however, may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used.

Setting up the FortiGate to operate in these new modes (or to operate in the other available operating modes) involves going to **System > Settings** and changing the **Inspection Mode** and **NGFW Mode**.

NGFW mode simplifies applying application control and web filtering to traffic by allowing you to add applications and web filtering profiles directly to policies.

Transparent proxy allows you to apply web authentication to HTTP traffic without using the explicit proxy.

Changing inspection and policy modes

To change inspection modes, go to **System > Settings**. You can select **Flow-based** or **Proxy** inspection modes.

NGFW mode

When you select **Flow-based** as the **Inspection Mode**, you have the option to select an **NGFW Mode**. In **NGFW Profile-based** mode, you configure Application Control and Web-Filtering profiles in **Security Profiles** and then apply them to a policy.

In **Policy-based** mode, you add applications and web filtering profiles directly to a policy without having to first create and configure Application Control or Web Filtering profiles.

When you change to **Flow-based** inspection, all proxy mode profiles are converted to flow mode, and proxy settings are removed. In addition, proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Go to **System > VDOM**. Click **Edit** for the VDOM you want to change and select the **Inspection Mode**.

CLI syntax

You can use the following CLI command to configure NGFW mode:

```
config system settings
  set inspection-mode flow
  set ngfw-mode {profile-based | policy-based}
  set ssl-ssh-profile "certificate-inspection"
end
```

Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

Security Profile Feature	Flow-based inspection	Proxy-based inspection
AntiVirus	x	x
Web Filter	x	x
DNS Filter	x	x
Application Control	x	x
Intrusion Protection	x	x
Anti-Spam		x
Data Leak Protection		x
VoIP		x
ICAP		x
Web Application Firewall		x
FortiClient Profiles	x	x
Proxy Options	x	x
SSL Inspection	x	x
SSH Inspection		x
Web Rating Overrides	x	x
Web Profile Overrides		x

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI, you can configure flow-based antivirus profiles, web filter profiles, and DLP profiles and they will appear on the GUI and include their inspection mode setting. Flow-based profiles created when in flow mode are still available when you switch to proxy mode.

In flow mode, antivirus and web filter profiles only include flow-mode features. Web filtering and virus scanning is still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

Antivirus features in proxy and flow mode

Feature	Proxy	Flow
Scan Mode (Quick or Full)		x
Detect viruses (Block or Monitor)	x	x
Inspected protocols	x	(all relevant protocols are inspected)
Inspection Options	x	x (not available for quick scan mode)
Treat Windows Executables in Email Attachments as Viruses	x	x
Send Files to FortiSandbox Appliance for Inspection	x	x
Use FortiSandbox Database	x	x
Include Mobile Malware Protection	x	x

Web filter features in proxy and flow mode

Feature	Proxy	Flow
FortiGuard category based filter	x	x (show, allow, monitor, block)
Category Usage Quota	x	
Allow users to override blocked categories (on some models)	x	
Search Engines	x	

Feature		Proxy	Flow
	Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex	x	
	Restrict YouTube Access	x	
	Log all search keywords	x	
Static URL Filter		x	x
	Block invalid URLs	x	
	URL Filter	x	x
	Block malicious URLs discovered by FortiSandbox	x	x
	Web Content Filter	x	x
Rating Options		x	x
	Allow websites when a rating error occurs	x	x
	Rate URLs by domain and IP Address	x	x
	Block HTTP redirects by rating	x	
	Rate images by URL	x	
Proxy Options		x	
	Restrict Google account usage to specific domains	x	
	Provide details for blocked HTTP 4xx and 5xx errors	x	
	HTTP POST Action	x	
	Remove Java Applets	x	
	Remove ActiveX	x	
	Remove Cookies	x	
	Filter Per-User Black/White List	x	

Basic administration

This section contains information about basic FortiGate administration that can be done after you have installed the unit in your network.

While this section mainly focuses on accomplishing tasks with the GUI, some tasks include instructions to use the CLI. You can access the CLI using the GUI or FortiExplorer, or via SSH or Telnet connection. For more information about the CLI, see [Using the CLI](#).

Registration

In order to have full access to Fortinet Support and FortiGuard Services, you must register your FortiGate.

Registering your FortiGate:

1. Go to the **Dashboard** and locate the **Licenses** widget.
2. Click on **FortiCare Support** to display a pop-up window and **Register**.
3. In the pop-up window, either use an existing Fortinet Support account or create a new one. Select your **Country** and **Reseller**.
4. Select **OK**.

FortiGate platforms do not impose any limitations on the number or type of customers, users, devices, IP addresses, or number of VPN clients being served by the platform. Such factors are limited solely by the hardware capacity of each given model.

System Settings

There are several system settings that should be configured once your FortiGate is installed:

- [Default administrator password](#)
- [Settings](#)
 - [Changing the host name](#)
 - [System Time](#)
 - [Administration Settings](#)
 - [Password Policy](#)
 - [View Settings](#)
- [Administrator password retries and lockout time](#)

Default administrator password

By default, your FortiGate has an administrator account set up with the username `admin` and no password. In order to prevent unauthorized access to the FortiGate, it is highly recommended that you add a password to this account.

To change the default password:

1. Go to **System > Administrators**.
2. Edit the **admin** account.

3. Select **Change Password**.
4. Enter the **New Password** and re-enter the password for confirmation.
5. Select **OK**.

For details on selecting a password and password best practices, see the section on [Passwords](#).

It is also recommended to change the user name of this account; however, since you cannot change the user name of an account that is currently in use, a second administrator account will need to be created in order to do this. For more information about creating and using administrator accounts, see the Administrators section of the [System Administration](#) chapter.

Settings

Settings can be accessed by going to **System > Settings**. On this page, you can change the **Host name**, set the system time and identify time zone in **System Time**, configure HTTP, HTTPS, SSH, and Telnet ports as well as idle timeout in **Administration Settings**, designate the **Password Policy**, and manage display options and designate inspection mode in **View Settings**.

Changing the host name

The host name of your FortiGate appears in the **Hostname** row in the **System Information** widget on the Dashboard. The host name also appears at the CLI prompt when you are logged in to the CLI, and as the SNMP system name.

To change the host name on the FortiGate

Go to **System > Settings** and type in the new name in the **Host name** row. The only administrators that can change a FortiGate's host name are administrators whose admin profiles permit system configuration write access. If the FortiGate is part of an HA cluster, you should use a unique host name to distinguish the FortiGate from others in the cluster.

System Time

For effective scheduling and logging, the FortiGate system time and date should be accurate. You can either manually set the system time and date or configure the FortiGate to automatically synchronize with a Network Time Protocol (NTP) server.

NTP enables you to keep the FortiGate time synchronized with other network systems. By enabling NTP on the FortiGate, FortiOS will check with the NTP server you select at the configured intervals. This will also ensure that logs and other time-sensitive settings on the FortiGate are correct.

The FortiGate maintains its internal clock using a built-in battery. At start up, the time reported by the FortiGate will indicate the hardware clock time, which may not be accurate. When using NTP, the system time might change after the FortiGate has successfully obtained the time from a configured NTP server.

By default, FortiOS has the daylight savings time configuration enabled. The system time must be manually adjusted after daylight saving time ends. To disable DST, enter the following commands in the CLI:

```
config system global
  set dst disable
end
```

To set the date and time

1. Go to the **System > Settings**.
2. Under **System Time**, select your **Time Zone** by using the drop-down menu.
3. **Set Time** by either selecting **Synchronize with NTP Server** or **Manual settings**. If you select synchronization, you can either use the default FortiGuard servers or specify a custom server. You can also set the **Sync interval**.
4. If you use an NTP server, you can identify a specific interface for this self-originating traffic by enabling **Setup device as local NTP server**.
5. Select **Apply**.

Administration Settings

In order to improve security, you can change the default port configurations for administrative connections to the FortiGate. When connecting to the FortiGate when the port has changed, the port must be included, such as `https://<ip_address>:<port>`. For example, if you are connecting to the FortiGate using port 99, the URL would be `https://192.168.1.99:99`.

To configure the port settings:

1. Go to **System > Settings**.
2. Under **Administration Settings**, change the port numbers for HTTP, HTTPS, SSH, and/or Telnet as needed. You can also select **Redirect to HTTPS** in order to avoid HTTP being used for the administrators.
3. Select **Apply**.

When you change the default port number for HTTP, HTTPS, SSH, or Telnet, ensure that the port number is unique. If a conflict exists with a particular port, a warning message will appear.

By default, the GUI disconnects administrative sessions if no activity occurs for five minutes. This prevents someone from using the GUI if the management PC is left unattended.

To change the idle timeout

1. Go to **System > Settings**.
2. In the **Administration Settings** section, enter the time in minutes in the **Idle timeout** field.
3. Select **Apply**.

Password Policy

The FortiGate includes the ability to create a password policy for administrators and IPsec pre-shared keys. With this policy, you can enforce regular changes and specific criteria for a password including:

- minimum length between 8 and 64 characters.
- if the password must contain uppercase (A, B, C) and/or lowercase (a, b, c) characters.
- if the password must contain numbers (1, 2, 3).
- if the password must contain special or non-alphanumeric characters (!, @, #, \$, %, ^, &, *, (, and)).
- where the password applies (admin or IPsec or both).
- the duration of the password before a new one must be specified.

To create a password policy - GUI

1. Go to **System > Settings**.
2. Configure **Password Policy** settings as required.
3. Click **Apply**.

If you add a password policy or change the requirements on an existing policy, the next time that administrator logs into the FortiGate, they are prompted to update their password to meet the new requirements before proceeding to log in.

For information about recovering a lost password and enhancements to the process, see: [Resetting a lost Admin password](#) on the Fortinet Cookbook site.

View Settings

Three settings can change the presentation of information in the GUI: **Language**, **Lines per page**, and **Theme**.

To change the language, go to **System > Settings**. Select the language you want from the **Language** drop-down list: English (the default), French, Spanish, Portuguese, Japanese, Traditional Chinese, Simplified Chinese, or Korean. For best results, you should select the language that is used by the management computer.

To change the number of lines per page displayed in the GUI tables, set **Lines per page** to a value between 20 and 1,000. The default is 50 lines per page.

Five color themes are currently available: Green (the default), Red, Blue, Melongene, and Mariner. To change your theme, select the color from the **Theme** drop-down list.

This is also where you select either **Flow-based** or **Proxy Inspection Mode**. If you select Flow-based mode, then you need to specify if it is **NGFW Profile-based** or **NGFW Policy-based** inspection.

Administrator password retries and lockout time

By default, the FortiGate sets the number of password retries at three, allowing the administrator a maximum of three attempts to log into their account before locking the account for a set amount of time.

Both the number of attempts (`admin-lockout-threshold`) and the wait time before the administrator can try to enter a password again (`admin-lockout-duration`) can be configured within the CLI.

To configure the lockout options:

```
config system global
    set admin-lockout-threshold <failed_attempts>
    set admin-lockout-duration <seconds>
end
```

The default value of `admin-lockout-threshold` is 3 and the range of values is between 1 and 10. The `admin-lockout-duration` is set to 60 seconds by default and the range of values is between 1 and 4294967295 seconds.

Keep in mind that the higher the lockout threshold, the higher the risk that someone may be able to break into the FortiGate.

Example:

To set the `admin-lockout-threshold` to one attempt and the `admin-lockout-duration` to a five minute duration before the administrator can try to log in again, enter the commands:

```
config system global
  set admin-lockout-threshold 1
  set admin-lockout-duration 300
end
```

If the time span between the first failed login attempt and the `admin-lockout-threshold` failed login attempt is less than `admin-lockout-duration`, the lockout will be triggered.

Passwords

Using secure passwords are vital for preventing unauthorized access to your FortiGate. When changing the password, consider the following to ensure better security:

- Do not make passwords that are obvious, such as the company name, administrator names, or other obvious words or phrases.
- Use numbers in place of letters, for example, `passw0rd`.
- Administrator passwords can be up to 64 characters.
- Include a mixture of letters, numbers, and upper and lower case.
- Use multiple words together, or possibly even a sentence, for example `keytothehighway`.
- Use a password generator.
- Change the password regularly and always make the new password unique and not a variation of the existing password, such as changing from `password` to `password1`.
- Make note of the password and store it in a safe place away from the management computer, in case you forget it or ensure that at least two people know the password in the event that one person becomes ill, is away on vacation, or leaves the company. Alternatively, have two different admin logins.

Downgrades will typically maintain the administrator password. If you need to downgrade to FortiOS 4.3, remove the password before the downgrade, then log in after the downgrade and re-configure the password.

Password policy

The FortiGate includes the ability to create a password policy for administrators and IPsec pre-shared keys. With this policy, you can enforce regular changes and specific criteria for a password including:

- minimum length between 8 and 64 characters.
- if the password must contain uppercase (A, B, C) and/or lowercase (a, b, c) characters.
- if the password must contain numbers (1, 2, 3).
- if the password must contain special or non-alphanumeric characters (!, @, #, \$, %, ^, &, *, (, and)).
- where the password applies (admin or IPsec or both).
- the duration of the password before a new one must be specified.

To create a password policy - GUI

1. Go to **System > Settings**.
2. Configure **Password Policy** settings as required.
3. Click **Apply**.

If you add a password policy or change the requirements on an existing policy, the next time that administrator logs into the FortiGate, they are prompted to update their password to meet the new requirements before proceeding to log in.

For information about recovering a lost password and enhancements to the process, see: [Resetting a lost Admin password](#) on the Fortinet Cookbook site.

Firmware

Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues. After you have registered your FortiGate unit, you can download firmware updates from the support web site, <https://support.fortinet.com>.

Before you install any new firmware, be sure to follow the steps below:

- Review the [Release Notes](#) for a new firmware release.
- Review the [Supported Upgrade Paths](#) Sys Admin note on the Fortinet Cookbook site to make sure the upgrade from your current image to the desired new image is supported.
- Backup the current configuration, including local certificates.
- Test the new firmware until you are satisfied that it applies to your configuration.

Installing new firmware without reviewing release notes or testing the firmware may result in changes to settings or unexpected issues.

Only FortiGate admin users and administrators whose access profiles contain system read and write privileges can change the FortiGate firmware.

Backing up the current configuration

You should always back up the configuration before installing new firmware, in case you need to restore your FortiGate configuration.

To create a local backup:

1. Open to the administrator's dropdown menu in the top-right corner of the GUI and select **Configuration > Backup**.
2. Choose either **Local PC** or **USB Disk** to save the configuration file. The USB option will not be available if there is no USB drive in the USB port.
3. If desired, select **Encryption**.
4. Select **OK**.

For more information, see [Configuration Backups](#).

Restoring configuration

Rather than reconfigure the FortiGate manually, it is possible to upload a saved configuration file.

To restore your FortiGate configuration:

1. Open to the administrator's dropdown menu in the top-right corner of the GUI and select **Configuration > Restore**.
2. Choose either **Local PC** or **USB Disk** to restore the configuration file from.
3. Select **Upload** beside **File**.
4. Locate and then select the correct file in the file manager window.
5. If a password was associated with the configuration file, enter it in the **Password** field.
6. Select **OK**.

Troubleshooting

During the installation, some possible errors may occur, but the solutions are usually straightforward.

Error message	Reason and Solution
Configuration file error	<p>This error occurs when attempting to upload a configuration file that is incompatible with the device. This may be due to the configuration file being for a different model or being saved from a different version of firmware.</p> <p>Solution: Upload a configuration file that is for the correct model of FortiGate device and the correct version of the firmware.</p>
Invalid password	<p>When the configuration file is saved, it can be protected by a password. The password entered during the upload process is not matching the one associated with the configuration file.</p> <p>Solution: Use the correct password if the file is password protected.</p>

Downloading firmware

Firmware images for all FortiGate units are available on the Fortinet Customer Support website, <https://support.fortinet.com>.

To download firmware:

1. Log into the site using your user name and password.
2. Go to **Download > Firmware Images**.
3. A list of Release Notes is shown. If you have not already done so, download and review the Release Notes for the firmware you wish to upgrade your FortiGate unit to.
4. Select **Download**.

Firmware can also be downloaded using FTP; however, as FTP is not an encrypted file transferring protocol, HTTPS downloading is recommended.

5. Navigate to the folder for the firmware version you wish to use.
6. Select your FortiGate model from the list. If your unit is a FortiWiFi, the firmware will have a filename starting with 'FWF'.
7. Save the firmware image to your computer.

Testing new firmware

The integrity of firmware images downloaded from Fortinet's support portal can be verified using a file checksum. A file checksum that does not match the expected value indicates a corrupt file. The corruption could be caused by errors in transfer or by file modification. A list of expected checksum values for each build of released code is available on Fortinet's support portal.

Image integrity is also verified when the FortiGate is booting up. This integrity check is done through a cyclic redundancy check (CRC). If the CRC fails, the FortiGate unit will encounter an error during the boot process.

Lastly, firmware images are signed and the signature is attached to the code as it is built. When upgrading an image, the running OS will generate a signature and compare it with the signature attached to the image. If the signatures do not match, the new OS will not load.

Testing before installation

FortiOS lets you test a new firmware image by installing the firmware image from a system reboot and saving it to system memory. After completing this procedure, the FortiGate unit operates using the new firmware image with the current configuration. This new firmware image is not permanently installed. The next time the FortiGate unit restarts, it operates with the originally installed firmware image using the current configuration. If the new firmware image operates successfully, you can install it permanently using the procedure explained in [Testing new firmware on page 117](#).

To use this procedure, you must connect to the CLI using the FortiGate console port and an RJ-45 to DB-9 or null modem cable. This procedure temporarily installs a new firmware image using your current configuration.

For this procedure, you must install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

To test the new firmware image:

1. Connect to the CLI using an RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the FortiGate unit can connect to the TFTP server using the `execute ping` command.
5. Enter the following command to restart the FortiGate unit:
`execute reboot`
6. As the FortiGate unit reboots, press any key to interrupt the system startup. As the FortiGate unit starts, a series of system startup messages appears:
Press any key to display configuration menu....
7. Immediately press any key to interrupt the system startup.

You have only three (3) seconds to press any key. If you do not press a key quickly enough, the FortiGate unit reboots and you must log in and repeat the `execute reboot` command.

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.
[F]: Format boot device.
[B]: Boot with backup firmware and set as default
[C]: Configuration and information
[Q]: Quit menu and continue to boot with default firmware.
[H]: Display this list of options.
Enter G, F, Q, or H:
```

8. Type **G** to get the new firmware image from the TFTP server. The following message appears:

```
Enter TFTP server address [192.168.1.168]:
```

9. Type the address of the TFTP server and press **Enter**. The following message appears:

```
Enter Local Address [192.168.1.188]:
```

10. Type an IP address of the FortiGate unit to connect to the TFTP server. The IP address must be on the same network as the TFTP server.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image file name and press **Enter**. The TFTP server uploads the firmware image file to the FortiGate unit and the following appears.

```
Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]
```

12. Type **R**. The FortiGate image is installed to system memory and the FortiGate unit starts running the new firmware image, but with its current configuration.

You can test the new firmware image as required. When done testing, you can reboot the FortiGate unit, and the FortiGate unit will resume using the firmware that was running before you installed the test firmware.

Upgrading the firmware

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date. You can also use the CLI command `execute update-now` to update the antivirus and attack definitions. For more information, see the [System Administration](#) handbook.

Always remember to back up your configuration before making any changes to the firmware.

Be sure to read the topics on [downloading](#) and [testing](#) firmware before upgrading.

To upgrade the firmware - GUI:

1. Log into the GUI as the admin administrative user.
2. Go to **System > Firmware**.
3. Under **Upload Firmware**, select **Browse** and locate the firmware image file.
4. Select **OK**.

The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, restarts, and displays the FortiGate login. This process takes a few minutes.

To upgrade the firmware - CLI:

Before you begin, ensure you have a TFTP server running and accessible to the FortiGate unit.

1. Make sure the TFTP server is running.
2. Copy the new firmware image file to the root directory of the TFTP server.
3. Log into the CLI.
4. Make sure the FortiGate unit can connect to the TFTP server. You can use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

```
execute ping 192.168.1.168
```

5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

```
execute restore image tftp <filename> <tftp_ipv4>
```

Where `<name_str>` is the name of the firmware image file and `<tftp_ipv4>` is the IP address of the TFTP server. For example, if the firmware image file name is `image.out` and the IP address of the TFTP server is `192.168.1.168`, enter:

```
execute restore image tftp image.out 192.168.1.168
```

The FortiGate unit responds with the message:

```
This operation will replace the current firmware version!  
Do you want to continue? (y/n)
```

6. Type `y`. The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, and restarts. This process takes a few minutes.
7. Reconnect to the CLI.
8. Update antivirus and attack definitions, by entering:

```
execute update-now
```

Reverting to a previous firmware version

The following procedure reverts the FortiGate unit to its factory default configuration and deletes any configuration settings. If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Always remember to back up your configuration before making any changes to the firmware.

To revert to a previous firmware version - GUI:

1. Log into the GUI as the admin user.
2. Go to **System > Firmware**.
3. Under **Upload Firmware**, select **Browse** and locate the firmware image file.
4. Select **OK**.

The FortiGate unit uploads the firmware image file, reverts to the old firmware version, resets the configuration, restarts, and displays the FortiGate login. This process takes a few minutes.

To revert to a previous firmware version - CLI:

Before beginning this procedure, it is recommended that you:

- Backup the FortiGate unit system configuration using the command

```
execute backup config.
```
- Backup the IPS custom signatures using the command

```
execute backup ipsuserdefs sig.
```
- Backup web content and email filtering lists.

To use the following procedure, you must have a TFTP server the FortiGate unit can connect to.

1. Make sure the TFTP server is running.
2. Copy the firmware image file to the root directory of the TFTP server.

3. Log into the FortiGate CLI.
4. Make sure the FortiGate unit can connect to the TFTP server by using the `execute ping` command.
5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

```
execute restore image tftp <name_str> <tftp_ipv4>
```

Where `<name_str>` is the name of the firmware image file and `<tftp_ipv4>` is the IP address of the TFTP server. For example, if the firmware image file name is `imagev28.out` and the IP address of the TFTP server is `192.168.1.168`, enter:

```
execute restore image tftp image28.out 192.168.1.168
```

The FortiGate unit responds with this message:

```
This operation will replace the current firmware version!
Do you want to continue? (y/n)
```

6. Type `y`. The FortiGate unit uploads the firmware image file. After the file uploads, a message similar to the following appears:

```
Get image from tftp server OK.
Check image OK.
This operation will downgrade the current firmware version!
Do you want to continue? (y/n)
```

7. Type `y`. The FortiGate unit reverts to the old firmware version, resets the configuration to factory defaults, and restarts. This process takes a few minutes.
8. Reconnect to the CLI.
9. To restore your previous configuration, if needed, use the command:

```
execute restore config <name_str> <tftp_ipv4>
```

10. Update antivirus and attack definitions using the command:

```
execute update-now
```

Installing firmware from a system reboot - CLI

In the event that the firmware upgrade does not load properly and the FortiGate unit will not boot, or continuously reboots, it is best to perform a fresh install of the firmware from a reboot using the CLI.

This procedure installs a firmware image and resets the FortiGate unit to default settings. You can use this procedure to upgrade to a new firmware version, revert to an older firmware version, or re-install the current firmware.

To use this procedure, you must connect to the CLI using the FortiGate console port and a RJ-45 to DB-9, or null modem cable. This procedure reverts the FortiGate unit to its factory default configuration.

For this procedure you install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

Before beginning this procedure, ensure you backup the FortiGate unit configuration.

If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

To install firmware from a system reboot:

1. Connect to the CLI using the RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the internal interface is connected to the same network as the TFTP server.
5. To confirm the FortiGate unit can connect to the TFTP server, use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

```
execute ping 192.168.1.168
```

6. Enter the following command to restart the FortiGate unit.

```
execute reboot
```

The FortiGate unit responds with the following message:

```
This operation will reboot the system!  
Do you want to continue? (y/n)
```

7. Type **y**. As the FortiGate unit starts, a series of system startup messages appears. When the following messages appears:

```
Press any key to display configuration menu.....
```

Immediately press any key to interrupt the system startup.

You have only three (3) seconds to press any key. If you do not press a key quickly enough, the FortiGate unit reboots and you must log in and repeat the `execute reboot` command.

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.  
[F]: Format boot device.  
[B]: Boot with backup firmware and set as default  
[C]: Configuration and information  
[Q]: Quit menu and continue to boot with default firmware.  
[H]: Display this list of options.  
Enter G, F, Q, or H:
```

8. Type **G** to get to the new firmware image from the TFTP server. The following message appears:

```
Enter TFTP server address [192.168.1.168]:
```

9. Type the address of the TFTP server and press **Enter**. The following message appears:

```
Enter Local Address [192.168.1.188]:
```

10. Type an IP address the FortiGate unit can use to connect to the TFTP server. The IP address can be any IP address that is valid for the network to which the interface is connected.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image filename and press **Enter**.

The TFTP server uploads the firmware image file to the FortiGate unit and a message similar to the following

appears:

```
Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]
```

12. Type **D**. The FortiGate unit installs the new firmware image and restarts. The installation might take a few minutes to complete.

Restore from a USB key - CLI

1. Log into the CLI.
2. Enter the following command to restore an unencrypted configuration file:

```
exec restore image usb <filename>
```

If your configuration file was encrypted, enter the following command:

```
execute restore config usb-mode <password>
```

The FortiGate unit responds with the following message:

```
This operation will replace the current firmware version!  
Do you want to continue? (y/n)
```

3. Type **y**.

Controlled upgrade

Using a controlled upgrade, you can upload a new version of the FortiOS firmware to a separate partition in the FortiGate memory for later upgrade. The FortiGate unit can also be configured so that when it is rebooted, it will automatically load the new firmware (CLI only). Using this option, you can stage a number of FortiGate units to do an upgrade simultaneously to all devices using FortiManager or script.

To load the firmware for later installation - CLI:

```
execute restore secondary-image {ftp | tftp | usb} <filename_str>
```

To set the FortiGate unit so that when it reboots, the new firmware is loaded, use the CLI command . . .

```
execute set-next-reboot {primary | secondary}
```

where {primary | secondary} is the partition with the preloaded firmware.

Configuration backups

Once you successfully configure the FortiGate, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it. You should also backup the local certificates, as the unique SSL inspection CA and server certificates that are generated by your FortiGate by default are not saved in a system backup.

It is also recommended that you backup the configuration after *any* future changes are made, to ensure you have the most current configuration available. Also, backup the configuration before any upgrades of the FortiGate's firmware. Should anything happen to the configuration during the upgrade, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP, and TFTP server. The last two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

Backing up the configuration using the GUI

1. Click on **admin** in the upper right-hand corner of the screen and select **Configuration > Backup**.
2. Direct the backup to your **Local PC** or to a **USB Disk**.
The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
3. If VDOMs are enabled, indicate whether the scope of the backup is for the entire FortiGate configuration (**Global**) or only a specific VDOM configuration (**VDOM**).
4. If backing up a VDOM configuration, select the VDOM name from the list.
5. Select **Encryption**.
Encryption must be enabled on the backup file to back up VPN certificates.
6. Enter a password and enter it again to confirm it. You will need this password to restore the file.
7. Select **OK**.
8. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

Backing up the configuration using the CLI

Use one of the following commands:

```
execute backup config management-station <comment>
```

or:

```
execute backup config usb <backup_filename> [<backup_password>]
```

or for FTP, note that port number, username are optional depending on the FTP site:

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]
[<password>]
```

or for TFTP:

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
edit <vdom_name>
```

Backup and restore the local certificates

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate before you enter the command.

To back up the local certificates:

Connect to the CLI and use the following command:

```
execute vpn certificate local export tftp <cert_name> <filename> <tftp_ip>
```

where:

- <cert_name> is the name of the server certificate.
- <filename> is a name for the output file.
- <tftp_ip> is the IP address assigned to the TFTP server host interface.

To restore the local certificates - GUI:

1. Move the output file from the TFTP server location to the management computer.
2. Go to **System > Certificates** and select **Import**.
3. Select the appropriate type of certificate from the dropdown menu and fill in any required fields.
4. Select **Upload**. Browse to the location on the management computer where the exported file has been saved, select the file and select **Open**.
5. If required, enter the **Password** needed to upload the exported file.
6. Select **OK**.

To restore the local certificates - CLI:

Connect to the CLI and use the following command:

```
execute vpn certificate local import tftp <filename> <tftp_ip>
```

Backup and restore a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for an administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate. SCP is enabled using the CLI commands:

```
config system global
set admin-scp enable
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
    set admin-scp enable
end
config vdom
    edit <vdom_name>
```

Enable SSH access on the interface

SCP uses the SSH protocol to provide secure file transfer. The interface you use for administration must allow SSH access.

To enable SSH - GUI:

1. Go to **Network > Interfaces**.
2. Select the interface you use for administrative access and select **Edit**.
3. In the **Administrative Access** section, select **SSH**.
4. Select **OK**.

To enable SSH - CLI:

```
config system interface
    edit <interface_name>
        set allowaccess ping https ssh
    end
```

When adding to, or removing a protocol, you must type the entire list again. For example, if you have an access list of HTTPS and SSH, and you want to add PING, typing:

```
set allowaccess ping
```

will only set PING. To add all three, you must type:

```
set allowaccess https ssh ping
```

Using the SCP client

The FortiGate downloads the configuration file as `sys_conf`. Use the following syntax to download the file:

Linux

```
scp admin@<FortiGate_IP>:fgt-config <location>
```

Windows

```
pscp admin@<FortiGate_IP>:fgt-config <location>
```

The following examples show how to download the configuration file from a FortiGate-100D, at IP address 172.20.120.171, using Linux and Windows SCP clients.

Linux client example

To download the configuration file to a local directory called `~/config`, enter the following command:

```
scp admin@172.20.120.171:fgt-config ~/config
```

Enter the admin password when prompted.

Windows client example

To download the configuration file to a local directory called c:\config, enter the following command in a Command Prompt window:

```
pscp admin@172.20.120.171:fgt-config c:\config
```

Enter the admin password when prompted.

SCP public-private key authentication

SCP authenticates itself to the FortiGate in the same way as an administrator using SSH accesses the CLI. Instead of using a password, you can configure the SCP client and the FortiGate with a public-private key pair.

To configure public-private key authentication:

1. Create a public-private key pair using a key generator compatible with your SCP client.
2. Save the private key to the location on your computer where your SSH keys are stored.
This step depends on your SCP client. The Secure Shell key generator automatically stores the private key.

3. Copy the public key to the FortiGate using the CLI commands:

```
config system admin
  edit admin
    set ssh-public-key1 "<key-type> <key-value>"
  end
```

<key-type> must be the ssh-dss for a DSA key or ssh-rsa for an RSA key. For the <key-value>, copy the public key data and paste it into the CLI command.

If you are copying the key data from Windows Notepad, copy one line at a time and ensure that you paste each line of key data at the end of the previously pasted data. Also:

- Do not copy the end-of-line characters that appear as small rectangles in Notepad.
- Do not copy the ---- BEGIN SSH2 PUBLIC KEY ---- or Comment: "[2048-bit dsa,...]" lines.
- Do not copy the ---- END SSH2 PUBLIC KEY ---- line.

4. Type the closing quotation mark and press **Enter**.

Your SCP client can now authenticate to the FortiGate based on SSH keys rather than the administrator password.

Restoring a configuration using SCP

To restore the configuration using SCP, use the commands:

```
scp <local_file> <admin_user>@<FGT_IP>:fgt-restore-config
```

To use this command/method of restoring the FortiGate configuration, you need to log in as the "admin" administrator.

Restoring a configuration

Should you need to restore a configuration file, use the following steps:

To restore the FortiGate configuration - GUI:

1. Click on **admin** in the upper right-hand corner of the screen and select **Configuration > Restore**.
2. Identify the source of the configuration file to be restored : your **Local PC** or a **USB Disk**.
The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can restore from the FortiManager using the CLI.
3. Enter the path and file name of the configuration file, or select **Browse** to locate the file.
4. Enter a password if required.
5. Select **Restore**.

To back up the FortiGate configuration - CLI:

```
execute restore config management-station normal 0
```

or:

```
execute restore config usb <filename> [<password>]
```

or for FTP, note that port number, username are optional depending on the FTP site:

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>] [<password>]
```

or for TFTP:

```
execute backup config tftp <backup_filename> <tftp_server> <password>
```

The FortiGate will load the configuration file and restart. Once the restart has completed, verify that the configuration has been restored.

Configuration revision

You can manage multiple versions of configuration files on models that have a 512MB flash memory and higher. Revision control requires either a configured central management server or the local hard drive, if your FortiGate has this feature. Typically, configuration backup to local drive is not available on lower-end models.

The central management server can either be a FortiManager unit or FortiCloud.

If central management is not configured on your FortiGate unit, a message appears instructing you to either:

- Enable central management, **or**
- obtain a valid license.

When revision control is enabled on your FortiGate unit, and configuration backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration revisions are viewed by clicking on **admin** in the upper right-hand corner of the screen and selecting **Configuration > Revisions**.

Restore factory defaults

There may be a need to reset the FortiGate to its original defaults; for example, to begin with a fresh configuration. There are two options when restoring factory defaults. The first resets the entire device to the original out-of-the-box configuration.

You can reset using the CLI by entering the command:

```
execute factoryreset
```

When prompted, type `y` to confirm the reset.

Alternatively, in the CLI you can reset the factory defaults but retain the interface and VDOM configuration. Use the following command:

```
execute factoryreset2
```

FortiGuard

The FortiGuard Distribution Network (FDN) of servers provides updates to antivirus, antispyware, and IPS definitions to your FortiGate. FortiGuard Subscription Services provides comprehensive Unified Threat Management (UTM) security solutions to enable protection against content and network level threats.

The FortiGuard team can be found around the globe, monitoring virus, spyware and vulnerability activities. As vulnerabilities are found, signatures are created and pushed to the subscribed FortiGates. The Global Threat Research Team enables Fortinet to deliver a combination of multi-layered security intelligence and provide true zero-day protection from new and emerging threats. The FortiGuard Network has data centers around the world located in secure, high availability locations that automatically deliver updates to the Fortinet security platforms to protect the network with the latest information.

FortiGuard provides a number of services to monitor world-wide activity and provide the best possible security, including:

- **Intrusion Prevention System (IPS)** - IPS uses a customizable database of more than 4000 known threats to stop attacks that evade conventional firewall defenses. It also provides behavior-based heuristics, enabling the system to recognize threats when no signature has yet been developed. It also provides more than 1000 application identity signatures for complete application control.
- **Application Control** - Application Control allows you to identify and control applications on networks and endpoints regardless of port, protocol, and IP address used. It gives you unmatched visibility and control over application traffic, even traffic from unknown applications and sources. Application Control is a free FortiGuard service and the database for Application Control signatures is separate from the IPS database (Botnet Application signatures are still part of the IPS signature database since these are more closely related with security issues and less about application detection). Application Control signature database information is displayed under the **System > FortiGuard** page in the FortiCare section.

Please note that while the Application Control profile can be used for free, signature database updates require a valid FortiGuard subscription.

- **AntiVirus** - The FortiGuard AntiVirus Service provides fully automated updates to ensure protection against the latest content level threats. It employs advanced virus, spyware, and heuristic detection engines to prevent both new and evolving threats from gaining access to your network and protects against vulnerabilities.
- **Web Filtering** - Web Filtering provides Web URL filtering to block access to harmful, inappropriate, and dangerous web sites that may contain phishing/pharming attacks, malware such as spyware, or objectionable content that can expose your organization to legal liability. Based on automatic research tools and targeted research analysis, real-time updates enable you to apply highly-granular policies that filter web access based on six major categories and nearly 80 micro-categories, over 45 million rated web sites, and more than two billion web pages - all continuously updated.
- **Email Filtering** - The FortiGuard Antispam Service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools on Fortinet appliances and agents, to detect and block a wide range of spam messages. Updates to the IP reputation and spam signature databases are provided continuously via the FDN.
- **Messaging Services** - Messaging Services allow a secure email server to be automatically enabled on your FortiGate to send alert email or send email authentication tokens. With the SMS gateway, you can enter phone numbers where the FortiGate will send the SMS messages. Note that depending on your carrier, there may be a slight time delay on receiving messages.

- **DNS and DDNS** - The FortiGuard DNS and DDNS services provide an efficient method of DNS lookups once subscribed to the FortiGuard network. This is the default option. The FortiGate connects automatically to the FortiGuard DNS server. If you do not register, you need to configure an alternate DNS server.

Configure the DDNS server settings using the CLI command:

```
config system fortiguard
    set ddns-server-ip
    set ddns-server-port
end
```

Support contract and FortiGuard subscription services

The FDN support **Contract** is available under **System > FortiGuard**.

The License Information area displays the status of your FortiGate's support contract.

You can also manually update the AntiVirus and IPS engines.

Verifying your connection to FortiGuard

If you are not getting FortiGuard web filtering or antispam services, there are a few things to verify that communication to the FDN is working. Before any troubleshooting, ensure that the FortiGate has been registered and subscribed to the FortiGuard services.

Verification - GUI:

The simplest method to check that the FortiGate is communicating with the FDN, is to check the **License Information** dashboard widget. Any subscribed services should have a green check mark beside them indicating that connections are successful. Any other icon indicates a problem with the connection, or you are not subscribed to the FortiGuard services.

You can also view the FortiGuard connection status by going to **System > FortiGuard**.

Verification - CLI:

You can also use the CLI to see what FortiGuard servers are available to your FortiGate. Use the following CLI command to ping the FDN for a connection:

```
execute ping guard.fortinet.net
```

You can also use the following diagnose command to find out what FortiGuard servers are available:

```
diagnose debug rating
```

From this command, you will see output similar to the following:

```
Locale : english
License : Contract
Expiration : Sun Jul 24 20:00:00 2011
Hostname : service.fortiguard.net
== Server List (Tue Nov 2 11:12:28 2010) ==
```

IP	Weight	RTT	Flags	TZ	Packets	Curr	Lost	Total	Lost
69.20.236.180	0	10		-5	77200	0	42		
69.20.236.179	0	12		-5	52514	0		34	
66.117.56.42	0	32		-5	34390	0		62	
80.85.69.38	50	164		0	34430	0		11763	
208.91.112.194	81	223	D	-8	42530	0		8129	
216.156.209.26	286	241	DI	-8	55602	0		21555	

An extensive list of servers are available. Should you see a list of three to five available servers, the FortiGuard servers are responding to DNS replies to service FortiGuard.net, but the INIT requests are not reaching FDS services on the servers.

The rating flags indicate the server status:

D	Indicates the server was found via the DNS lookup of the hostname. If the hostname returns more than one IP address, all of them will be flagged with 'D' and will be used first for INIT requests before falling back to the other servers.
I	Indicates the server to which the last INIT request was sent.
F	The server has not responded to requests and is considered to have failed.
T	The server is currently being timed.

The server list is sorted first by weight and then the server with the smallest RTT is put at the top of the list, regardless of weight. When a packet is lost, it will be resent to the next server in the list.

The weight for each server increases with failed packets and decreases with successful packets. To lower the possibility of using a distant server, the weight is not allowed to dip below a base weight, which is calculated as the difference in hours between the FortiGate and the server, multiplied by 10. The further away the server, the higher its base weight and the lower in the list it will appear.

Port assignment

The FortiGate contacts FDN for the latest list of FDN servers by sending UDP packets with typical source ports of 1027 or 1031, and destination port 8888. The FDN reply packets have a destination port of 1027 or 1031.

If your ISP blocks UDP packets in this port range, the FortiGate cannot receive the FDN reply packets. As a result, the FortiGate will not receive the complete FDN server list.

If your ISP blocks the lower range of UDP ports (around 1024), you can configure your FortiGate to use higher-numbered ports, using the CLI command:

```
config system global
    set ip-src-port-range <start port>-<end port>
end
```

where the <start port> and <end port> are numbers ranging of 1024 to 25000.

For example, you could configure the FortiGate to not use ports lower than 2048 or ports higher than the following range:

```
config system global
    set ip-src-port-range 2048-20000
end
```

Trial and error may be required to select the best source port range. You can also contact your ISP to determine the best range to use. Push updates might be unavailable if:

- there is a NAT device installed between the unit and the FDN, and/or
- your unit connects to the Internet using a proxy server.

Configuring AntiVirus and IPS options

Go to **System > FortiGuard**, and scroll down to the **AntiVirus & IPS Updates** section to configure the antivirus and IPS options for connecting and downloading definition files.

Accept push updates	Select to allow updates to be sent automatically to your FortiGate. New definitions will be added as soon as they are released by FortiGuard.
Use override push	<p>Appears only if Accept push updates is enabled.</p> <p>Enable to configure an override server if you cannot connect to the FDN or if your organization provides updates using their own FortiGuard server. Once enabled, enter the following:</p> <ul style="list-style-type: none"> • Enter the IP address and port of the NAT device in front of your FortiGate. FDS will connect to this device when attempting to reach the FortiGate. • The NAT device must be configured to forward the FDS traffic to the FortiGate on UDP port 9443.
Scheduled Updates	<p>Enable for updates to be sent to your FortiGate at a specific time. For example, to minimize traffic lag times, you can schedule the update to occur on weekends or after work hours.</p> <p>Note that a schedule of once a week means any urgent updates will not be pushed until the scheduled time. However, if there is an urgent update required, select the Update Now button.</p>
Improve IPS quality	Enable to help Fortinet maintain and improve IPS signatures. The information sent to the FortiGuard servers when an attack occurs can be used to keep the database current as variants of attacks evolve.
Use extended IPS signature package	Regular IPS database protects against the latest common and in-the-wild attacks. Extended IPS database includes protection from legacy attacks.
Update AV & IPS Definitions	Select to manually initiate an FDN update.

Manual updates

To manually update the signature definitions file, you need to first go to the Support web site at <https://support.fortinet.com>. Once logged in, select **Download > FortiGuard Service Updates**. The browser will present you the most current IPS and AntiVirus signature definitions which you can download.

Once downloaded to your computer, log into the FortiGate to load the definition file.

To load the definition file onto the FortiGate:

1. Go to **System > FortiGuard**.
2. In the **License Information** table, select the **Upgrade Database** link in either the **Application Control Signature**, **IPS**, or **AntiVirus** row.
3. In the pop-up window, select **Upload** and locate the downloaded file and select **Open**.

The upload may take a few minutes to complete.

Automatic updates

The FortiGate can be configured to request updates from FDN on a scheduled basis, or via push notification.

Scheduling updates

Scheduling updates ensures that the virus and IPS definitions are downloaded to your FortiGate on a regular basis, ensuring that you do not forget to check for the definition files yourself.

Updating definitions can cause a very short disruption in traffic currently being scanned while the FortiGate unit applies the new signature database. Ideally, schedule updates during off-peak hours, such as evenings or weekends, when network usage is minimal, to ensure that the network activity will not suffer from the added traffic of downloading the definition files.

To enable scheduled updates - GUI:

1. Go to **System > FortiGuard** and scroll down to **AntiVirus & IPS Updates**.
2. Enable **Scheduled Updates**.
3. Select the frequency of updates.
4. Select **Apply**.

To enable scheduled updates - CLI:

```
config system autoupdate schedule
  set status enable
  set frequency {every | daily | weekly}
  set time <hh:mm>
  set day <day_of_week>
end
```

Push updates

Push updates enable you to get immediate updates when new viruses or intrusions have been discovered and new signatures created. This ensures that the latest signature will be sent to the FortiGate as soon as possible.

When a push notification occurs, the FortiGuard server sends a notice to the FortiGate that there is a new signature definition file available. The FortiGate then initiates a download of the definition file, similar to the scheduled update.

To ensure maximum security for your network, you should have a scheduled update as well as enable the push update, in case an urgent signature is created, and your cycle of the updates only occurs weekly.

To enable push updates - GUI:

1. Go to **System > FortiGuard** and scroll down to **AntiVirus & IPS Updates**.
2. Enable **Accept push updates**.
3. Select **Apply**.

To enable push updates - CLI:

```
config system autoupdate push-update
  set status enable
```

end

Push IP override

If the FortiGate is behind another NAT device (or another FortiGate), to ensure it receives the push update notifications, you need to use an override IP address for the notifications. To do this, you create a virtual IP to map to the external port of the NAT device.

Generally speaking, if there are two FortiGate devices, the following steps need to be completed on the FortiGate NAT device to ensure the FortiGate on the internal network receives the updates:

- Add a port forwarding virtual IP to the FortiGate NAT device that connects to the Internet by going to **Policy & Objects > Virtual IPs**.
- Add a security policy to the FortiGate NAT device that connects to the Internet that includes the port forwarding virtual IP.
- Configure the FortiGate on the internal network with an override push IP and port.

On the FortiGate internal device, the virtual IP is entered as the **Use push override** IP address.

To enable push update override- GUI:

1. Go to **System > FortiGuard** and scroll down to **AntiVirus & IPS Updates**.
2. Enable **Accept push updates**.
3. Enable **Use override push**.
4. Enter the virtual IP address configured on the NAT device.
5. Select **Apply**.

To enable push updates - CLI:

```
config system autoupdate push-update
    set status enable
    set override enable
    set address <vip_address>
end
```

Sending malware statistics to FortiGuard

To support following malware trends and making zero-day discoveries, FortiGate units send encrypted statistics to FortiGuard about IPS, Application Control, and AntiVirus events detected by the FortiGuard services running on your FortiGate. FortiGuard uses the statistics collected to achieve a balance between performance and security effectiveness by moving inactive signatures to an extended signature database.

The statistics include some non-personal information that identifies your FortiGate and its country. The information is never shared with external parties. You can choose to disable the sharing of this information by entering the following CLI command:

```
config system global
    set fds-statistics disable
end
```

Configuring web filtering and email filtering options

Go to **System > FortiGuard**, and scroll down to **Filtering** to set the size of the caches and ports.

Web Filter Cache	Set the Time To Live (TTL) value. This is the number of seconds the FortiGate will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
Anti-Spam Cache	Set the TTL value (see above).
FortiGuard Filtering Port	Select the port assignments for contacting the FortiGuard servers.
Filtering Service Availability	Indicates the status of the filtering service. Select Check Again if the filtering service is not available.
Request re-evaluation of a URL's category	Select to re-evaluate a URL's category rating on the FortiGuard Web Filter service.

Email filtering

The FortiGuard data centers monitor and update email databases of known spam sources. With FortiGuard Anti-Spam filtering enabled, the FortiGate verifies incoming email sender addresses and IPs against the database, and takes the necessary actions as defined within the antivirus profiles.

Spam source IP addresses can also be cached locally on the FortiGate, providing a quicker response time, while easing load on the FortiGuard servers, aiding in a quicker response time for less common email address requests.

By default, the anti-spam cache is enabled. The cache includes a TTL value, which is the amount of time an email address will stay in the cache before expiring. You can change this value to shorten or extend the time between 5 and 1,440 minutes.

To modify the antispam cache TTL - GUI:

1. Go to **System > FortiGuard**.
2. Under **Filtering**, enable **Anti-Spam Cache**.
3. Enter the TTL value in minutes.
4. Select **Apply**.

To modify the Anti-Spam filter TTL - CLI:

```
config system fortiguard
    set antispam-cache-ttl <integer>
end
```

Further antispam filtering options can be configured to block, allow, or quarantine specific email addresses. These configurations are available through the **Security Profiles > Anti-Spam** menu. For more information, see the [Security Profiles](#) handbook chapter.

Online security tools

The FortiGuard online center provides a number of online security tools, including but not limited to:

- **URL lookup** — By entering a website address, you can see if it has been rated and what category and classification it is filed as. If you find your website or a site you commonly go to has been wrongly categorized, you can use this page to request that the site be re-evaluated.
<https://fortiguard.com/webfilter>
- **Threat Encyclopedia** — Browse the Fortiguard Labs extensive encyclopedia of threats. Search for viruses, botnet C&C, IPS, endpoint vulnerabilities, and mobile malware.
<https://www.fortiguard.com/encyclopedia>
- **Application Control** — Browse the Fortiguard Labs extensive encyclopedia of applications.
<https://fortiguard.com/appcontrol>

FortiCloud

FortiCloud is a hosted security management and log retention service for FortiGate devices. It gives you centralized reporting, traffic analysis, configuration management, and log retention without the need for additional hardware or software.

FortiCloud offers a wide range of features:

- **Simplified central management** — FortiCloud provides a central web-based management console to manage individual or aggregated FortiGate and FortiWiFi devices. Adding a device to the FortiCloud management subscription is straightforward. FortiCloud has detailed traffic and application visibility across the whole network.
- **Hosted log retention with large default storage allocated** — Log retention is an integral part of any security and compliance program but administering a separate storage system is burdensome. FortiCloud takes care of this automatically and stores the valuable log information in the cloud. Each device is allowed up to 200GB of log retention storage. Different types of logs can be stored including Traffic, System Events, Web, Applications, and Security Events.
- **Monitoring and alerting in real time** — Network availability is critical to a good end-user experience. FortiCloud enables you to monitor your FortiGate network in real time with different alerting mechanisms to pinpoint potential issues. Alerting mechanisms can be delivered via email.
- **Customized or pre-configured reporting and analysis tools** — Reporting and analysis are your eyes and ears into your network's health and security. Pre-configured reports are available, as well as custom reports that can be tailored to your specific reporting and compliance requirements. For example, you may want to look closely at application usage or website violations. The reports can be emailed as PDFs and can cover different time periods.
- **Maintain important configuration information uniformly** — The correct configuration of the devices within your network is essential to maintaining an optimum performance and security posture. In addition, maintaining the correct firmware (operating system) level allows you to take advantage of the latest features.
- **Service security** — All communication (including log information) between the devices and the clouds is encrypted. Redundant data centers are always used to give the service high availability. Operational security measures have been put in place to make sure your data is secure — only you can view or retrieve it.

Registration and activation

Before you can activate a FortiCloud account, you must first register your device.

FortiCloud accounts can be registered manually through the FortiCloud website, <https://www.forticloud.com>, but you can easily register and activate your account directly from your FortiGate.

Activating your FortiCloud account

1. On your device's dashboard, in the **FortiCloud** widget, select the **Activate** button in the status field.
2. A dialogue asking you to register your FortiCloud account appears. Select **Create Account**, enter your information, view and accept the terms and conditions, and select **OK**.
3. A second dialogue window appears, asking you to enter your information to confirm your account. This sends a confirmation email to your registered email. The dashboard widget then updates to show that confirmation is required.
4. Open your email, and follow the confirmation link it contains.

Results

A FortiCloud page will open, stating that your account has been confirmed. The Activation Pending message on the dashboard will change to state the type of account you have ('1GB Free' or '200GB Subscription'), and will provide a link to the FortiCloud portal.

Enabling logging to FortiCloud

1. Go to **Log & Report > Log Settings**.
2. Enable **Send Logs to FortiCloud**.
3. Select **Test Connectivity** to ensure that your FortiGate can connect to the registered FortiCloud account.
4. Scroll down to **GUI Preferences**, set **Display Logs/FortiView From**, to see FortiCloud logs within the FortiGate's GUI.

Logging into the FortiCloud portal

Once logging has been configured and you have registered your account, you can log into the FortiCloud portal and begin viewing your logging results. There are two methods to reach the FortiCloud portal:

- If you have direct networked access to the FortiGate, you can simply open your **Dashboard** and check the **License Information** widget. Next to the current FortiCloud connection status will be a link to reach the FortiCloud Portal.
- If you do not currently have access to the FortiGate's interface, you can visit the FortiCloud website (<https://forticloud.com>) and log in remotely, using your email and password. It will ask you to confirm the FortiCloud account you are connecting to and then you will be granted access. Connected devices can be remotely configured using the Scripts page in the Management Tab, useful if an administrator may be away from the unit for a long period of time.

Cloud sandboxing

FortiCloud can be used for automated sample tracking, or sandboxing, for files from a FortiGate. This allows suspicious files to be sent to be inspected without risking network security. If the file exhibits risky behavior, or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database.

Cloud sandboxing is configured by going to **Security Fabric > Settings**. After enabling **Sandbox Inspection**, select the **FortiSandbox type**.

Sandboxing results are shown in a new tab called **AV Submissions** in the FortiCloud portal. This tab only appears after a file has been sent for sandboxing.

For more information about FortiCloud, see the [FortiCloud documentation](#).

Troubleshooting your FortiGate installation

If your FortiGate does not function as desired after installation, try the following troubleshooting tips:

1. Check for equipment issues

Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network. You will also find detailed information about the FortiGate LED indicators.

The FortiGate has multiple LED lights on the faceplate. Check the [FortiGate LED specifications](#) guide to verify if the lights indicate any problems with your FortiGate itself or with connections between your FortiGate and other devices.

2. Check the physical network connections

Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.

3. Verify that you can connect to the internal IP address of the FortiGate

Connect to the GUI from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`.

If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the GUI, check the settings for administrative access on that interface. Alternatively, use SSH to connect to the CLI, and then confirm that HTTPS has been enabled for Administrative Access on the interface.

4. Check the FortiGate interface configurations

Check the configuration of the FortiGate interface connected to the internal network (under **Network > Interfaces**) and check that **Addressing mode** is set to the correct mode.

5. Verify the security policy configuration

Go to **Policy & Objects > IPv4 Policy** and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the **Active Sessions** column to ensure that traffic has been processed (if this column does not appear, right-click on the table header and select **Active Sessions**).

If you are using NAT/Route mode, check the configuration of the policy to make sure that **NAT** is enabled and that **Use Outgoing Interface Address** is selected.

6. Verify the static routing configuration

Go to **Network > Static Routes** and verify that the default route is correct. Go to **Monitor > Routing Monitor** and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as **Connected**, one for each connected FortiGate interface.

7. Verify that you can connect to the Internet-facing interface's IP address

Ping the IP address of the Internet-facing interface of your FortiGate. If you cannot connect to the interface, the FortiGate is not allowing sessions from the internal interface to Internet-facing interface. Verify that **PING** has been enabled for **Administrative Access** on the interface.

8. Verify that you can connect to the gateway provided by your ISP

Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.

9. Verify that you can communicate from the FortiGate to the Internet

Access the FortiGate CLI and use the command `execute ping 8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.

10. Verify the DNS configurations of the FortiGate and the PCs

Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping`

`www.fortinet.com`.

If the name cannot be resolved, the FortiGate or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.

11. Confirm that the FortiGate can connect to the FortiGuard network

Once the FortiGate is on your network, you should confirm that it can reach the FortiGuard network.

First, check the **License Information** widget to make sure that the status of all FortiGuard services matches the services that you have purchased.

Go to **System > FortiGuard**. Scroll down to **Filtering Services Availability** and select **Check Again**. After a minute, the GUI should indicate a successful connection.

Verify that your FortiGate can resolve and reach FortiGuard at *service.fortiguard.net* by pinging the domain name. If you can reach this service, you can then verify the connection to FortiGuard servers by running the command `diagnose debug rating`. This displays a list of FortiGuard IP gateways you can connect to, as well as the following information:

- **Weight:** Based on the difference in time zone between the FortiGate and this server
- **RTT:** Return trip time
- **Flags:** D (IP returned from DNS), I (Contract server contacted), T (being timed), F (failed)
- **TZ:** Server time zone
- **Curr Lost:** Current number of consecutive lost packets
- **Total Lost:** Total number of lost packets

12. Consider changing the MAC address of your external interface

Some ISPs do not want the MAC address of the device connecting to their network cable to change. If you have added a FortiGate to your network, you may have to change the MAC address of the Internet-facing interface using the following CLI command:

```
config system interface
  edit <interface>
    set macaddr <xx:xx:xx:xx:xx:xx>
  end
end
```

13. Check the FortiGate bridge table (transparent mode)

When a FortiGate is in transparent mode, the unit acts like a bridge sending all incoming traffic out on the other interfaces. The bridge is between interfaces on the FortiGate unit. Each bridge listed is a link between interfaces. Where traffic is flowing between interfaces, you expect to find bridges listed. If you are having connectivity issues and there are no bridges listed, that is a likely cause. Check for the MAC address of the interface or device in question.

To list the existing bridge instances on the FortiGate, use the following CLI command:

```
diagnose netlink brctl name host root.b
show bridge control interface root.b host.
fdb: size=2048, used=25, num=25, depth=1
Bridge root.b host table
port no device devname mac addr ttl attributes
3 4 wan1 00:09:0f:cb:c2:77 88
3 4 wan1 00:26:2d:24:b7:d3 0
3 4 wan1 00:13:72:38:72:21 98
4 3 internal 00:1a:a0:2f:bc:c6 6
1 6 dmz 00:09:0f:dc:90:69 0 Local Static
3 4 wan1 c4:2c:03:0d:3a:38 81
3 4 wan1 00:09:0f:15:05:46 89
3 4 wan1 c4:2c:03:1d:1b:10 0
2 5 wan2 00:09:0f:dc:90:68 0 Local Static
```

14. Use FortiExplorer if you can't connect to the FortiGate over Ethernet

If you can't connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer. Refer to the

QuickStart Guide or see the section on [FortiExplorer](#) for more details.

15. Either reset the FortiGate to factory defaults or contact Fortinet Support for assistance

To reset the FortiGate to factory defaults, use the CLI command `execute factoryreset`. When prompted, type `y` to confirm the reset.

You can also contact Fortinet Support for assistance. Read the following article found on the Fortinet Cookbook website: [How to work with Fortinet Support](#) to understand what type of support is available and to determine which level of support is right for you. For further assistance, visit the [Fortinet Support](#) website.

Resources

Here's a list of some resources you can check out next to help you get the most out of your newly installed and configured FortiGate.

Best Practices

The Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGates in a customer environment. It is updated periodically as new issues are identified.

This document can be found at <https://docs.fortinet.com/>.

The Fortinet Cookbook

The Fortinet Cookbook contains a variety of step-by-step examples of how to integrate a FortiGate into your network and apply features such as security profiles, wireless networking, and VPN.

Using the Cookbook, you can go from idea to execution in simple steps, configuring a secure network for better productivity with reduced risk.

The Fortinet Cookbook can be found at <http://cookbook.fortinet.com>.

The Fortinet Video Library

The Fortinet Video Library contains video tutorials showing how to configure various Fortinet products, including FortiGates. Many FortiGate videos are based on recipes from the FortiGate Cookbook.

The Fortinet Video Library can be found at <https://video.fortinet.com>. You can also [subscribe to Fortinet's YouTube channel](#).

The FortiOS Handbook

The FortiOS Handbook is the complete guide to FortiOS, covering a variety of FortiGate configurations. The Handbook is available as a single complete document online. Handbook chapters are also available as standalone documents.

The FortiOS Handbook can be found at <https://docs.fortinet.com/>.

Fortinet Support

You can also contact Fortinet Support for assistance. Read the following article found on the Fortinet Cookbook website: [How to work with Fortinet Support](#) to understand what type of support is available and to determine which level of support is right for you. For further information, go to <https://support.fortinet.com>.

Chapter 3 - Authentication

This Handbook chapter contains the following sections:

[Introduction to authentication](#) describes some basic elements and concepts of authentication.

[Authentication servers](#) describes external authentication servers, where a FortiGate unit fits into the topology, and how to configure a FortiGate unit to work with that type of authentication server.

[Users and user groups](#) describes the different types of user accounts and user groups. Authenticated access to resources is based on user identities and user group membership. Two-factor authentication methods, including FortiToken, provide additional security.

[Managing guest access](#) explains how to manage temporary accounts for visitors to your premises.

[Configuring authenticated access](#) provides detailed procedures for setting up authenticated access in security policies and authenticated access to VPNs.

[Captive portals](#) describes how to authenticate users through a web page that the FortiGate unit presents in response to any HTTP request until valid credentials are entered. This can be used for wired or WiFi network interfaces.

[Certificate-based authentication](#) describes authentication by means of X.509 certificates.

[Single sign-on using a FortiAuthenticator unit](#) describes how to use a FortiAuthenticator unit as an Single Sign-On (SSO) agent that can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit. Users can also log on through a FortiAuthenticator-based web portal or the FortiClient SSO Mobility Agent.

[Single sign-on to Windows AD](#) describes how to set up SSO in a Windows AD network by configuring the FortiGate unit to poll domain controllers for information user logons and user privileges.

[Agent-based FSSO](#) describes how to set up SSO in Windows AD, Citrix, or Novell networks by installing Fortinet Single Sign-On (FSSO) agents on domain controllers. The FortiGate unit receives information about user logons and allows access to network resources based on user group memberships.

[SSO using RADIUS accounting records](#) describes how to set up SSO in a network that uses RADIUS authentication. In this configuration, the RADIUS server send RADIUS accounting records to the FortiGate unit when users log on or off the network. The record includes a user group name that can be used in FortiGate security policies to determine which resources each user can access.

[Monitoring authenticated users](#) describes FortiOS authenticated user monitor screens.

[Examples and troubleshooting](#) provides configuration examples and troubleshooting suggestions.

What's new in FortiOS 6.0.1

The following list contains new authentication features added in FortiOS 6.0.1. Click on a link to navigate to that section for further information.

- [VMware Horizon support for TSSAgent \(for more information, see "Agent-based FSSO" on page 276\).](#)

What's new in FortiOS 6.0

The following list contains new authentication features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["Authentication binds to MAC address" on page 148](#)
- ["RADIUS accounting start message options" on page 160](#)
- ["UPN processing method and filter name" on page 167](#)
- ["IPv6 TACACS+ server IP address" on page 173](#)
- ["FortiToken extension to comply with PCI 3.2" on page 186](#)
- ["Login credentials for guest users shown in clear text on GUI and voucher" on page 196](#)
- ["Kerberos authentication for explicit web and transparent web proxy users" on page 218](#)
- ["IPv6 and captive portals" on page 235](#)
- ["Certificate-related protocols" on page 243](#)
- ["Agentless NTLM support" on page 285](#)
- ["Collector agent installation" on page 286](#)
- ["IPv6 support for FSSO" on page 315](#)

- [New Amazon device category \(for more information, see the \[FortiOS 6.0 CLI Reference\]\(#\)\)](#)

Introduction to authentication

Identifying users and other computers—authentication—is a key part of network security. This section describes some basic elements and concepts of authentication.

The following topics are included in this section:

- [What is authentication?](#)
- [Methods of authentication](#)
- [Types of authentication](#)
- [User's view of authentication](#)
- [FortiGate administrator's view of authentication](#)

What is authentication?

Businesses need to authenticate people who have access to company resources. In the physical world this may be a swipe card to enter the building, or a code to enter a locked door. If a person has this swipe card or code, they have been authenticated as someone allowed in that building or room.

Authentication is the act of confirming the identity of a person or other entity. In the context of a private computer network, the identities of users or host computers must be established to ensure that only authorized parties can access the network. The FortiGate unit enables controlled network access and applies authentication to users of security policies and VPN clients.

Methods of authentication

FortiGate unit authentication is divided into three basic types: password authentication for people, certificate authentication for hosts or endpoints, and two-factor authentication for additional security beyond just passwords. An exception to this is that FortiGate units in an HA cluster and FortiManager units use password authentication.

Password authentication verifies individual user identities, but access to network resources is based on membership in user groups. For example, a security policy can be configured to permit access only to the members of one or more user groups. Any user who attempts to access the network through that policy is then authenticated through a request for their username and password.

Methods of authentication include:

- [Local password authentication](#)
- [Server-based password authentication](#)
- [Certificate-based authentication](#)
- [Two-factor authentication](#)

Local password authentication

The simplest authentication is based on user accounts stored locally on the FortiGate unit. For each account, a username and password is stored. The account also has a disable option so that you can suspend the account without deleting it.

Local user accounts work well for a single-FortiGate installation. If your network has multiple FortiGate units that will use the same accounts, the use of an external authentication server can simplify account configuration and maintenance.

You can create local user accounts in the web-based manager under **User & Device > User Definition**. This page is also used to create accounts where an external authentication server stores and verifies the password.

Server-based password authentication

Using external authentication servers is desirable when multiple FortiGate units need to authenticate the same users, or where the FortiGate unit is added to a network that already contains an authentication server. FortiOS supports the use of LDAP, RADIUS, TACACS+, AD, or POP3 servers for authentication.

When you use an external authentication server to authenticate users, the FortiGate unit sends the user's entered credentials to the external server. The password is encrypted. The server's response indicates whether the supplied credentials are valid or not.

You must configure the FortiGate unit to access the external authentication servers that you want to use. The configuration includes the parameters that authenticate the FortiGate unit to the authentication server.

You can use external authentication servers in two ways:

- Create user accounts on the FortiGate unit. However, instead of storing each user's password, specify the server used to authenticate that user. As with accounts that store the password locally, you add these users to appropriate user groups.
- Add the authentication server to user groups. Any user who has an account on the server can be authenticated and have the access privileges of the FortiGate user group. Optionally, when an LDAP server is a FortiGate user group member, you can limit access to users who belong to specific groups defined on the LDAP server.

Certificate-based authentication

An RSA X.509 server certificate is a small file issued by a certificate authority (CA) that is installed on a computer or FortiGate unit to authenticate itself to other devices on the network. When one party on a network presents the certificate as authentication, the other party can validate that the certificate was issued by the CA. The identification is therefore as trustworthy as the CA that issued the certificate.

To protect against compromised or misused certificates, CAs can revoke any certificate by adding it to a certificate revocation list (CRL). Certificate status can also be checked online using the Online Certificate Status Protocol (OCSP).

RSA X.509 certificates are based on public-key cryptography, in which there are two keys: the private key and the public key. Data encrypted with the private key can be decrypted only with the public key, and the other way round. As the names suggest, the private key is never revealed to anyone and the public key can be freely distributed. Encryption with the recipient's public key creates a message that only the intended recipient can read. Encryption with the sender's private key creates a message whose authenticity is proven because it can be decrypted only with the sender's public key.

Server certificates contain a signature string encrypted with the CA's private key. The CA's public key is contained in a CA root certificate. If the signature string can be decrypted with the CA's public key, the certificate is genuine.

Certificate authorities

A CA can be:

- an organization, such as VeriSign Inc., that provides certificate services
- a software application, such as Microsoft Certificate Services or OpenSSH

For a company web portal or customer-facing SSL VPN, a third-party certificate service has some advantages. The CA certificates are already included in popular web browsers and customers trust the third-party. On the other hand, third-party services have a cost.

For administrators and for employee VPN users, the local CA based on a software application provides the required security at low cost. You can generate and distribute certificates as needed. If an employee leaves the organization, you can simply revoke their certificate.

Certificates for users

FortiGate unit administrators and SSL VPN users can install certificates in their web browsers to authenticate themselves. If the FortiGate unit uses a CA-issued certificate to authenticate itself to the clients, the browser will also need the appropriate CA certificate.

FortiGate IPsec VPN users can install server and CA certificates according to the instructions for their IPsec VPN client software. The FortiClient Endpoint Security application, for example, can import and store the certificates required by VPN connections.

FortiGate units are also compatible with some Public Key Infrastructure systems. For an example of this type of system, see [RSA ACE \(SecurID\) servers on page 176](#).

Two-factor authentication

A user can be required to provide both something they know (their username and password combination) and something they have (certificate or a random token code). Certificates are installed on the user's computer.

Two-factor authentication is available for PKI users. For more information, see [Certificate on page 186](#).

Another type of two-factor authentication is to use a randomly generated token (multi-digit number) along with the username and password combination. One method is a FortiToken — a one-time password (OTP) generator that generates a unique code every 60 seconds. Others use email or SMS text messaging to deliver the random token code to the user or administrator.

When one of these methods is configured, the user enters this code at login after the username and password have been verified. The FortiGate unit verifies the token code after as well as the password and username. For more information, see [Two-factor authentication on page 185](#)

Authentication binds to MAC address

In previous FortiOS versions, firewall authentication was source IP based, thus there was no action in response to a MAC address change. This was a security flaw that allowed an unauthenticated user to access restricted resources, especially in a WiFi environment where the IP and MAC binding changed frequently.

MAC addresses can now be bound with the user identity so that the MAC address is matched while matching an auth logon.

Types of authentication

FortiOS supports two different types of authentication based on your situation and needs: security policy authentication and Virtual Private Network (VPN) authentication.

Security policy authentication is easily applied to all users logging on to a network, or network service. For example if a group of users on your network such as the accounting department who have access to sensitive data need to access the Internet, it is a good idea to make sure the user is a valid user and not someone trying to send company secrets to the Internet. Security policy authentication can be applied to as many or as few users as needed, and it supports a number of authentication protocols to easily fit with your existing network.

VPN authentication enables secure communication with hosts located outside the company network, making them part of the company network while the VPN tunnel is operating. Authentication applies to the devices at both ends of the VPN and optionally VPN users can be authenticated as well.

Security policy authentication

Security policies enable traffic to flow between networks. Optionally, the policy can allow access only to specific originating addresses, device types, users or user groups. Where access is controlled by user or user group, users must authenticate by entering valid username and password credentials.

The user's authentication expires if the connection is idle for too long, five minutes by default but that can be customized.

Security policies are the mechanism for FSSO, NTLM, certificate based, and RADIUS SSO authentication.

FSSO

Fortinet Single Sign on (FSSO) provides seamless authentication support for Microsoft Windows Active Directory (AD) and Novell eDirectory users in a FortiGate environment.

On a Microsoft Windows or Novell network, users authenticate with the Active Directory or Novell eDirectory at login. FSSO provides authentication information to the FortiGate unit so that users automatically get access to permitted resources. See [Introduction to agent-based FSSO on page 276](#).

NTLM

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM is a browser-based method of authentication.

The FSSO software is installed on each AD server and the FortiGate unit is configured to communicate with each FSSO client. When a user successfully logs into their Windows PC (and is authenticated by the AD Server), the FSSO client communicates the user's name, IP address, and group login information to the FortiGate unit. The FortiGate unit sets up a temporary access policy for the user, so when they attempt access through the firewall they do not need to re-authenticate. This model works well in environments where the FSSO client can be installed on all AD servers.

In system configurations where it is not possible to install FSSO clients on all AD servers, the FortiGate unit must be able to query the AD servers to find out if a user has been properly authenticated. This is achieved using the NTLM messaging features of Active Directory and Internet Explorer.

Even when NTLM authentication is used, the user is not asked again for their username and password. Internet Explorer stores the user's credentials and the FortiGate unit uses NTLM messaging to validate them in the Windows AD environment.

Note that if the authentication reaches the timeout period, the NTLM message exchange restarts. For more information on NTLM, see [NTLM authentication on page 217](#) and [FSSO NTLM authentication support on page 282](#).

Certificates

Certificates can be used as part of a policy. All users being authenticated against the policy are required to have the proper certificate. See [Certificate-based authentication on page 241](#)

RADIUS SSO

RADIUS Single Sign-On (RSSO) is a remote authentication method that does not require any local users to be configured, and relies on RADIUS Start records to provide the FortiGate unit with authentication information. That information identifies the user and user group, which is then matched using a security policy. See [SSO using RADIUS accounting records on page 321](#).

FortiGuard web filter override authentication

Optionally, users can be allowed the privilege of overriding FortiGuard Web Filtering to view blocked web sites. Depending on the override settings, the override can apply to the user who requested it, the entire user group to which the user belongs, or all users who share the same web filter profile. As with other FortiGate features, access to FortiGuard overrides is controlled through user groups. Firewall and Directory Services user groups are eligible for the override privilege. For more information about web filtering and overrides, see the UTM chapter of this FortiOS Handbook.

VPN authentication

Authentication involves authenticating the user. In IPsec VPNs authenticating the user is optional, but authentication of the peer device is required.

This section includes:

- [Authenticating IPsec VPN peers \(devices\)](#)
- [Authenticating IPsec VPN users](#)
- [Authenticating SSL VPN users](#)
- [Authenticating PPTP and L2TP VPN users](#)

Authenticating IPsec VPN peers (devices)

A VPN tunnel has one end on a local trusted network, and the other end is at a remote location. The remote peer (device) must be authenticated to be able to trust the VPN tunnel. Without that authentication, it is possible for a malicious hacker to masquerade as a valid VPN tunnel device and gain access to the trusted local network.

The three ways to authenticate VPN peers are with a pre-shared key, RSA X.509 certificate, or a specific peer ID value.

The simplest way for IPsec VPN peers to authenticate each other is through the use of a pre-shared key, also called a shared secret. The pre-shared key is a text string used to encrypt the data exchanges that establish the VPN tunnel. The pre-shared key must be six or more characters. The VPN tunnel cannot be established if the two peers do not use the same key. The disadvantage of pre-shared key authentication is that it can be difficult to securely distribute and update the pre-shared keys.

RSA X.509 certificates are a better way for VPN peers to authenticate each other. Each peer offers a certificate signed by a Certificate Authority (CA) which the other peer can validate with the appropriate CA root certificate. For more information about certificates, see [Certificate-based authentication on page 241](#).

You can supplement either pre-shared key or certificate authentication by requiring the other peer to provide a specific peer ID value. The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating IPsec VPN users

An IPsec VPN can be configured to accept connections from multiple dynamically addressed peers. You would do this to enable employees to connect to the corporate network while traveling or from home. On a FortiGate unit, you create this configuration by setting the **Remote Gateway** to **Dialup User**.

It is possible to have an IPsec VPN in which remote peer devices authenticate using a common pre-shared key or a certificate, but there is no attempt to identify the user at the remote peer. To add user authentication, you can do one of the following:

- require a unique pre-shared key for each peer
- require a unique peer ID for each peer
- require a unique peer certificate for each peer
- require additional user authentication (XAuth)

The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating SSL VPN users

SSL VPN users can be

- user accounts with passwords stored on the FortiGate unit
- user accounts authenticated by an external RADIUS, LDAP or TACACS+ server
- PKI users authenticated by certificate

You need to create a user group for your SSL VPN. Simply create a firewall user group, enable SSL VPN access for the group, and select the web portal the users will access.

SSL VPN access requires an SSL VPN security policy that permits access to members of your user group.

Authenticating PPTP and L2TP VPN users

PPTP and L2TP are older VPN tunneling protocols that do not provide authentication themselves. FortiGate units restrict PPTP and L2TP access to users who belong to one specified user group. Users authenticate themselves to the FortiGate unit by username/password. You can configure PPTP and L2TP VPNs only in the CLI. Before you configure the VPN, create a firewall user group and add to it the users who are permitted to use the VPN. Users are authenticated when they attempt to connect to the VPN. For more information about configuring PPTP or L2TP VPNs, see the FortiGate CLI Reference.

Single sign-on authentication for users

Single sign-on (SSO) means that users logged on to a computer network are authenticated for access to network resources through the FortiGate unit without having to enter their username and password again. FortiGate units directly provide SSO capability for:

- Microsoft Windows networks using either Active Directory or NTLM authentication
- Novell networks, using eDirectory

In combination with a FortiAuthenticator unit, the FortiGate unit can provide SSO capability that integrates multiple external network authentication systems such as Windows Active Directory, Novell e-Directory, RADIUS and LDAP. The FortiAuthenticator unit gathers user logon information from all of these sources and sends it to the FortiGate unit.

Through the SSO feature, the FortiGate unit knows the username, IP address, and external user groups to which the user belongs. When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

For detailed information about SSO, see

- [Single sign-on using a FortiAuthenticator unit on page 263](#)
- [Agent-based FSSO on page 276](#)

User's view of authentication

From the user's point of view, they see a request for authentication when they try to access a protected resource, such as an FTP repository of intellectual property or simply access a website on the Internet. The way the request is presented to the user depends on the method of access to that resource.

VPN authentication usually controls remote access to a private network.

Web-based user authentication

Security policies usually control browsing access to an external network that provides connection to the Internet. In this case, the FortiGate unit requests authentication through the web browser.

The user types a username and password and then selects **Continue** or **Login**. If the credentials are incorrect, the authentication screen is redisplayed with blank fields so that the user can try again. When the user enters valid credentials, access is granted to the required resource. In some cases, if a user tries to authenticate several times without success, a message appears, such as: "Too many bad login attempts. Please try again in a few minutes." This indicates the user is locked out for a period of time. This prevents automated brute force password hacking attempts. The administrator can customize these settings if required.

After a defined period of user inactivity (the authentication timeout, defined by the FortiGate administrator), the user's access expires. The default is 5 minutes. To access the resource, the user will have to authenticate again.

VPN client-based authentication

A VPN provides remote clients with access to a private network for a variety of services that include web browsing, email, and file sharing. A client program such as FortiClient negotiates the connection to the VPN and manages the user authentication challenge from the FortiGate unit.

FortiClient can store the username and password for a VPN as part of the configuration for the VPN connection and pass them to the FortiGate unit as needed. Or, FortiClient can request the username and password from the user when the FortiGate unit requests them.

Social ID data from FortiClient is recorded so that if an email or phone number is changed on FortiClient, the new values are updated on the FortiGate.

The data is sent in KeepAlive messages in the following format:

```
USR_NAME|<full name for the service account>|USR_
EMAIL|<email for the service
account>|SERVICE|<os|custom|linkedin|google|salesforce>|
```

SSL VPN is a form of VPN that can be used with a standard Web browser. There are two modes of SSL VPN operation (supported in NAT/Route mode only):

- web-only mode, for remote clients equipped with a web-browser only
- tunnel mode, for remote computers that run a variety of client and server applications.

After a defined period of user inactivity on the VPN connection (the idle timeout, defined by the FortiGate administrator), the user's access expires. The default is 30 minutes. To access the resource, the user will have to authenticate again.

FortiGate administrator's view of authentication

Authentication is based on user groups. The FortiGate administrator configures authentication for security policies and VPN tunnels by specifying the user groups whose members can use the resource. Some planning is required to determine how many different user groups need to be created. Individual user accounts can belong to multiple groups, making allocation of user privileges very flexible.

A member of a user group can be:

- a user whose username and password are stored on the FortiGate unit
- a user whose name is stored on the FortiGate unit and whose password is stored on a remote or external authentication server
- a remote or external authentication server with a database that contains the username and password of each person who is permitted access

The general process of setting up authentication is as follows:

1. If remote or external authentication is needed, configure the required servers.
2. Configure local and peer (PKI) user identities. For each local user, you can choose whether the FortiGate unit or a remote authentication server verifies the password. Peer members can be included in user groups for use in security policies.
3. Create user groups.
4. Add local/peer user members to each user group as appropriate. You can also add an authentication server to a user group. In this case, all users in the server's database can authenticate. You can only configure peer user groups through the CLI.
5. Configure security policies and VPN tunnels that require authenticated access.

For authentication troubleshooting, see the specific chapter for the topic or for general issues see [Troubleshooting on page 348](#).

General authentication settings

Go to **User & Device > Authentication Settings** to configure authentication timeout, protocol support, and authentication certificates.

When user authentication is enabled within a security policy, the authentication challenge is normally issued for any of the four protocols (depending on the connection protocol):

- HTTP (can also be set to redirect to HTTPS)
- HTTPS
- FTP
- Telnet

The selections made in the **Protocol Support** list of **Authentication Settings** control which protocols support the authentication challenge. Users must connect with a supported protocol first so they can subsequently connect with other protocols. If HTTPS is selected as a method of protocol support, it allows the user to authenticate with a customized Local certificate.

When you enable user authentication within a security policy, the security policy user will be challenged to authenticate. For user ID and password authentication, users must provide their user names and passwords. For certificate authentication (HTTPS or HTTP redirected to HTTPS only), you can install customized certificates on the unit and the users can also have customized certificates installed on their browsers. Otherwise, users will see a warning message and have to accept a default Fortinet certificate.

Authentication Timeout	Enter a length of time in minutes, from 1 to 4320 (72 hours). Authentication timeout controls how long an authenticated firewall connection can be idle before the user must authenticate again. The default value is 5.
Protocol Support	Select the protocols to challenge during firewall user authentication.
Certificate	If using HTTPS protocol support, select the local certificate to use for authentication. Available only if HTTPS protocol support is selected.
Apply	Select to apply the selections for user authentication settings.

Authentication servers

FortiGate units support the use of external authentication servers. An authentication server can provide password checking for selected FortiGate users or it can be added as a member of a FortiGate user group.

If you are going to use authentication servers, you must configure the servers before you configure FortiGate users or user groups that require them.

Mac OS and iOS devices, including iPhones and iPads, can perform user authentication with FortiOS units using RADIUS servers, but not with LDAP or TACACS+ servers.

This section includes the following topics:

- [FortiAuthenticator servers](#)
- [RADIUS servers](#)
- [LDAP servers](#)
- [TACACS+ servers](#)
- [POP3 servers](#)
- [SSO servers](#)
- [RSA ACE \(SecurID\) servers](#)

FortiAuthenticator servers

FortiAuthenticator is an Authentication, Authorization, and Accounting (AAA) server, that includes a RADIUS server, an LDAP server, and can replace the FSSO Collector Agent on a Windows AD network. Multiple FortiGate units can use a single FortiAuthenticator for FSSO, remote authentication, and FortiToken management.

For more information, see the [FortiAuthenticator Administration Guide](#).

RADIUS servers

Remote Authentication and Dial-in User Service (RADIUS) is a broadly supported client-server protocol that provides centralized authentication, authorization, and accounting functions. RADIUS clients are built into gateways that allow access to networks such as Virtual Private Network servers, Network Access Servers (NAS), as well as network switches and firewalls that use authentication. FortiGate units fall into the last category.

RADIUS servers use UDP packets to communicate with the RADIUS clients on the network to authenticate users before allowing them access to the network, to authorize access to resources by appropriate users, and to account or bill for those resources that are used. RADIUS servers are currently defined by RFC 2865 (RADIUS) and RFC 2866 (Accounting), and listen on either UDP ports 1812 (authentication) and 1813 (accounting) or ports 1645 (authentication) and 1646 (accounting) requests. RADIUS servers exist for all major operating systems.

You must configure the RADIUS server to accept the FortiGate unit as a client. FortiGate units use the authentication and accounting functions of the RADIUS server.

FortiOS does not accept all characters from auto generated keys from MS Windows 2008. These keys are very long and as a result RADIUS authentication will not work. Maximum key length for MS Windows 2008 is 128 bytes. In older versions of FSAE, it was 40 bytes.

Microsoft RADIUS servers

Microsoft Windows Server 2000, 2003, and 2008 have RADIUS support built-in. Microsoft specific RADIUS features are defined in RFC 2548. The Microsoft RADIUS implementation can use Active Directory for user credentials.

For details on Microsoft RADIUS server configurations, refer to Microsoft documentation.

RADIUS user database

The RADIUS user database is commonly an SQL or LDAP database, but can also be any combination of:

- usernames and passwords defined in a configuration file
- user account names and passwords configured on the computer where the RADIUS server is installed.

If users are members of multiple RADIUS groups, then the user group authentication timeout value does not apply. See [Membership in multiple groups on page 199](#).

RADIUS authentication with a FortiGate unit

To use RADIUS authentication with a FortiGate unit

- configure one or more RADIUS servers on the FortiGate unit
- assign users to a RADIUS server

When a configured user attempts to access the network, the FortiGate unit will forward the authentication request to the RADIUS server which will match the username and password remotely. Once authenticated the RADIUS server passes the authorization granted message to the FortiGate unit which grants the user permission to access the network.

The RADIUS server uses a “shared secret” key along with MD5 hashing to encrypt information passed between RADIUS servers and clients, including the FortiGate unit. Typically only user credentials are encrypted. Additional security can be configured through IPsec tunnels by placing the RADIUS server behind another VPN gateway.

RADIUS attribute value pairs

RADIUS packets include a set of attribute value pairs (AVP) to identify information about the user, their location and other information. The FortiGate unit sends the following RADIUS attributes.

FortiOS supported RADIUS attributes

RADIUS Attribute	Name	Description	AVP type
1	Acct-Session-ID	Unique number assigned to each start and stop record to make it easy to match them, and to eliminate duplicate records.	44

RADIUS Attribute	Name	Description	AVP type
2	Username	Name of the user being authenticated	1
3	NAS-Identifier	Identifier or IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	32
4	Framed-IP-Address	Address to be configured for the user.	8
5	Fortinet-VSA	See Vendor-specific attributes on page 158	26
6	Acct-Input-Octets	Number of octets received from the port over the course of this service being provided. Used to charge the user for the amount of traffic they used.	42
7	Acct-Output-Octets	Number of octets sent to the port while delivering this service. Used to charge the user for the amount of traffic they used.	43
8	NAS-IP-Address	IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	4
9	Called-Station-Id	Used to send the telephone number the user called as part of the Access-Request packet.	30
10	Framed-IP-Address	IP address to be configured for the user, by sending the IP address of a user to the RADIUS server in the Access-Request packet.	8
11	Event-Timestamp	Records the time that the event occurred on the NAS. The timestamp is measured in seconds since January 1, 1970 00:00 UTC. Before the Event-Timestamp attribute can be sent in a packet, make sure that the correct time is set on the FortiGate.	55
12	Class	Used in accounting packets and requests for firewall, WiFi, and proxy authentication. The attribute is returned in Access-Account message and is added to all accounting packets.	25

The following table describes the supported authentication events and the RADIUS attributes that are sent in the RADIUS accounting message.

RADIUS attributes sent in RADIUS accounting message

Authentication Method	RADIUS Attributes						
	1	2	3	4	5	6	7
Web	X	X	X		X		
XAuth of IPsec (without DHCP)	X	X	X		X		
XAuth of IPsec (with DHCP)	X	X	X	X	X		
PPTP/L2TP (in PPP)	X	X	X	X	X	X	X
SSL-VPN	X	X	X	X	X		

External captive portal POST message

In external RADIUS captive portal, the captive portal web page is a script that gathers the user's logon credentials and sends it back to the FortiGate as a POST message. Session URL parameters are sent from the client in a POST messages, and in the redirect. These parameters are separated by **&** characters (see examples below):

POST message to redirect server:

```
http://<redirectserver>/index2.php/?login&post=http://192.168.200.1:1000/fgtauth&magic=02050f889bc21644&usermac=54:26:96:16:a2:45&apmac=00:09:0f:b9:f4:c0&apip=127.0.0.1&userip=192.168.200.2
```

POST message back to the FortiGate:

```
http://FGT_IP_addr:1000/fgtauth
```

The magic text data, provided in the initial FortiGate request to the web server, contains the username, password parameters:

```
magic=00050c839182f095&username=<username>&password=<password>
```

Vendor-specific attributes

Vendor specific attributes (VSA) are the method RADIUS servers and client companies use to extend the basic functionality of RADIUS. Some major vendors, such as Microsoft, have published their VSAs, however many do not.

In order to support vendor-specific attributes (VSA), the RADIUS server requires a dictionary to define which VSAs to support. This dictionary is typically supplied by the client or server vendor.

The Fortinet RADIUS vendor ID is 12356.

The FortiGate unit RADIUS VSA dictionary is supplied by Fortinet and is available through the Fortinet Knowledge Base (<http://kb.forticare.com>) or through Technical Support. Fortinet's dictionary for FortiOS 4.0 and up is configured this way:

```
##
```

```

Fortinet's VSA's
#
VENDOR fortinet 12356
BEGIN-VENDOR fortinet
ATTRIBUTE Fortinet-Group-Name 1 string
ATTRIBUTE Fortinet-Client-IP-Address 2 ipaddr
ATTRIBUTE Fortinet-Vdom-Name 3 string
ATTRIBUTE Fortinet-Client-IPv6-Address 4 octets
ATTRIBUTE Fortinet-Interface-Name 5 string
ATTRIBUTE Fortinet-Access-Profile 6 string
#
# Integer Translations
#
END-VENDOR Fortinet

```

Note that using the Fortinet-Vdom-Name, users can be tied to a specific VDOM on the FortiGate unit. See the documentation provided with your RADIUS server for configuration details.

RADIUS CoA support

As of FortiOS 5.4, RADIUS Change of Authorization (CoA) settings can be configured via the CLI. CoA is a common feature in user authentication that provides the ability to change authentication attributes for sessions even after they have authenticated.

User, user group, and captive portal authentication supports RADIUS CoA, when the back end authentication server is RADIUS. The main use case of this feature is with external captive portal, where it can be used to disconnect hotspot users when their time, credit, or bandwidth has been used up.

The commands below control CoA settings.

1. Set the name of the FortiAP connected to the FortiGate as a location identifier.

```

config system global
set alias <name>

```

2. Set URL of external authentication logout server.

```

config vdom
edit root
config wireless-controller vap
edit <example>
set security captive-portal
set external-logout

```

3. Set URL of external authentication logout server

```

config vdom
edit root
config system interface
edit <example>
set security captive-portal
set security-external-logout

```

4. Set class name(s) included in an Access-Accept message.

```

config vdom
edit root
config user radius
edit accounting
set class <"A1=aaa" "B2=bbb" "C3=ccc">

```

Role-based access control

In role-based access control (RBAC), network administrators and users have varying levels of access to network resources based on their role, and that role's requirement for access specific resources. For example, a junior accountant does not require access to the sales presentations, or network user account information.

There are three main parts to RBAC: role assignment, role authorization, and transaction authorization. Role assignment is accomplished when someone in an organization is assigned a specific role by a manager or HR. Role authorization is accomplished when a network administrator creates that user's RADIUS account and assigns them to the required groups for that role. Transaction authorization occurs when that user logs on and authenticates before performing a task.

RBAC is enforced when FortiOS network users are remotely authenticated via a RADIUS server. For users to authenticate, a security policy must be matched. That policy only matches a specific group of users. If VDOMs are enabled, the matched group will be limited to a specific VDOM. Using this method network administrators can separate users into groups that match resources, protocols, or VDOMs. It is even possible to limit users to specific FortiGate units if the RADIUS servers serve multiple FortiOS units.

For more information on security policies, see [Authentication in security policies on page 212](#).

RADIUS password encoding

Certain RADIUS servers use ISO-8859-1 password encoding instead of others such as UTF-8. In these instances, the server will fail to authenticate the user, if the user's password is using UTF-8.

CLI syntax

```
config user radius
  edit <example>
    set password-encoding <auto | ISO-8859-1>
  end
```

This option will be skipped if the `auth-type` is neither `auto` nor `pap`.

RADIUS accounting start message options

Administrators can now choose between sending accounting start messages to all configured accounting servers, or just the one server that was previously connected.

Syntax

```
config user radius
  edit <name>
    set acct-interim-interval <seconds>
    set acct-all-servers {enable | disable}
  next
end
```

Configuring the FortiGate unit to use a RADIUS server

The information you need to configure the FortiGate unit to use a RADIUS server includes

- the RADIUS server's domain name or IP address
- the RADIUS server's shared secret key.

You can optionally specify the NAS IP or Called Station ID. When configuring the FortiGate to use a RADIUS server, the FortiGate is a Network Access Server (NAS). If the FortiGate interface has multiple IP addresses, or you want the RADIUS requests to come from a different address you can specify it here. Called Station ID applies to carrier networks. However, if the NAS IP is not included in the RADIUS configuration, the IP of the FortiGate unit interface that communicates with the RADIUS server is used instead.

A maximum of 10 remote RADIUS servers can be configured on the FortiGate unit. One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see [Local and remote users on page 182](#).

On the FortiGate unit, the default port for RADIUS traffic is 1812. Some RADIUS servers use port 1645. If this is the case with your server, you can either:

- Re-configure the RADIUS server to use port 1812. See your RADIUS server documentation for more information on this procedure.

or

- Change the FortiGate unit default RADIUS port to 1645 using the CLI:

```
config system global
    set radius-port 1645
end
```

One wildcard admin account can be added to the FortiGate unit when using RADIUS authentication. This uses the wildcard character to allow multiple admin accounts on RADIUS to use a single account on the FortiGate unit. See [Example — wildcard admin accounts - CLI on page 168](#).

To configure the FortiGate unit for RADIUS authentication - web-based manager:

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**.

Name	A name to identify the RADIUS server on the FortiGate unit.
Authentication method	If you know the RADIUS server uses a specific authentication protocol, select Specify and select it from the list. Otherwise select Default . The Default option will usually work.
NAS IP	Enter the IP address to be used as the NAS-IP-Address attribute in RADIUS access requests.
Include in every user group	When enabled this RADIUS server will automatically be included in all user groups. This is useful if all users will be authenticating with the remote RADIUS server.

Primary Server

IP/Name: Enter the domain name (such as fgt.exmaple.com) or the IP address of the RADIUS server.

Secret: Enter the server secret key, such as radiusSecret. This can be a maximum of 16 characters long. This must match the secret on the RADIUS primary server.

Test Connectivity: Test the validity of the **IP/Name**.

Test User Connectivity: Test the validity of the **Secret**.

Secondary Server

IP/Name: Optionally enter the domain name (such as fgt.exmaple.com) or the IP address of the secondary RADIUS server.

Secret: Optionally, enter the secondary server secret key, such as radiusSecret2. This can be a maximum of 16 characters long. This must match the secret on the RADIUS secondary server.

Test Connectivity: Test the validity of the **IP/Name**.

Test User Connectivity: Test the validity of the **Secret**.

For MAC OS and iOS devices to authenticate, you must use MS-CHAP-v2 authentication. In the CLI, the command is `set auth-type ms_chap_v2`.

3. Select **OK**.

To configure the FortiGate unit for RADIUS authentication - CLI example:

```
config user radius
  edit ourRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret radiusSecret
  end
```

For more information about RADIUS server options, refer to the FortiGate CLI Reference.

Troubleshooting RADIUS

To test the connection to the RADIUS server use the following command:

```
diagnose test authserver radius-direct <server_name or IP> <port number> <secret>
```

For the port number, enter -1 to use the default port. Otherwise enter the port number to check.

Test results show RADIUS server reachability, NAS client rejection, and invalid User/Password. Test also shows RADIUS Attributes returned from the RADIUS server.

LDAP servers

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, and printers. LDAP consists of a data-representation scheme, a set of defined operations, and a request/response network.

The scale of LDAP servers range from big public servers such as BigFoot and Infospace, to large organizational servers at universities and corporations, to small LDAP servers for workgroups that may be using OpenLDAP. This document focuses on the institutional and workgroup applications of LDAP.

This section includes:

- [Components and topology](#)
- [LDAP directory organization](#)
- [Configuring the FortiGate unit to use an LDAP server](#)
- [Example — wildcard admin accounts - CLI](#)
- [Example of LDAP to allow dial-in through member-attribute - CLI](#)
- [Troubleshooting LDAP](#)

Components and topology

LDAP organization starts with directories. A directory is a set of objects with similar attributes organized in a logical and hierarchical way. Generally, an LDAP directory tree reflects geographic and organizational boundaries, with the Domain name system (DNS) names to structure the top level of the hierarchy. The common name identifier for most LDAP servers is `cn`, however some servers use other common name identifiers such as `uid`.

When LDAP is configured and a user is required to authenticate the general steps are:

1. The FortiGate unit contacts the LDAP server for authentication.
2. To authenticate with the FortiGate unit, the user enters a username and password.
3. The FortiGate unit sends this username and password to the LDAP server.
4. If the LDAP server can authenticate the user, the user is successfully authenticated with the FortiGate unit.
5. If the LDAP server cannot authenticate the user, the connection is refused by the FortiGate unit.

Binding

Binding is the step where the LDAP server authenticates the user. If the user is successfully authenticated, binding allows the user access to the LDAP server based on that user's permissions.

The FortiGate unit can be configured to use one of three types of binding:

- anonymous - bind using anonymous user search
- regular - bind using username/password and then search
- simple - bind using a simple password authentication without a search

You can use simple authentication if the user records all fall under one domain name (`dn`). If the users are under more than one `dn`, use the anonymous or regular type, which can search the entire LDAP database for the required username.

If your LDAP server requires authentication to perform searches, use the regular type and provide values for username and password.

Supported versions

The FortiGate unit supports LDAP protocol functionality defined in RFC 2251: Lightweight Directory Access Protocol v3, for looking up and validating user names and passwords. FortiGate LDAP supports all LDAP servers compliant with LDAP v3, including FortiAuthenticator. In addition, FortiGate LDAP supports LDAP over SSL/TLS, which can be configured only in the CLI.

FortiGate LDAP does not support proprietary functionality, such as notification of password expiration, which is available from some LDAP servers. FortiGate LDAP does not supply information to the user about why authentication failed.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

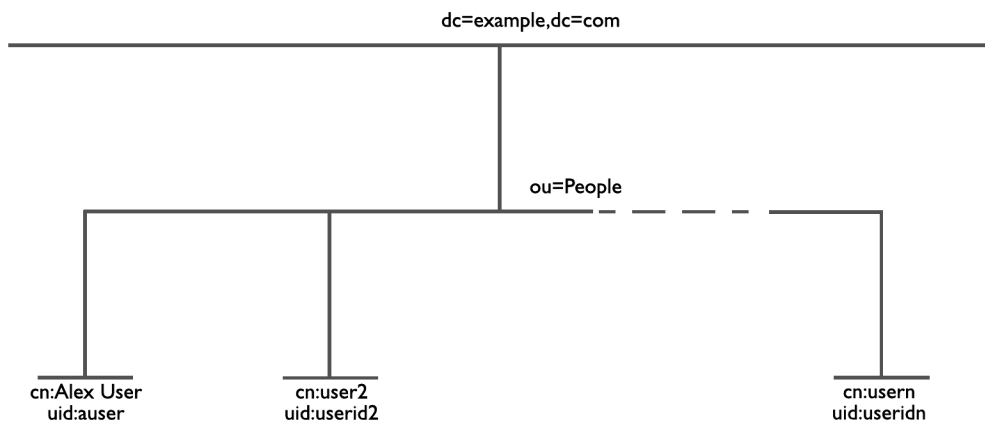

LDAP directory organization

To configure your FortiGate unit to work with an LDAP server, you need to understand the organization of the information on the server.

The top of the hierarchy is the organization itself. Usually this is defined as Domain Component (DC), a DNS domain. If the name contains a dot, such as `example.com`, it is written as two parts separated by a comma: `dc=example,dc=com`.

In this example, Common Name (CN) identifiers reside at the Organization Unit (OU) level, just below DC. The Distinguished Name (DN) is `ou=People,dc=example,dc=com`.

LDAP object hierarchy

In addition to the DN, the FortiGate unit needs an identifier for the individual person. Although the FortiGate unit GUI calls this the Common Name (CN), the identifier you use is not necessarily CN. On some servers, CN is the full name of a person. It might be more convenient to use the same identifier used on the local computer network. In this example, User ID (UID) is used.

Locating your identifier in the hierarchy

You need to determine the levels of the hierarchy from the top to the level that contain the identifier you want to use. This defines the DN that the FortiGate unit uses to search the LDAP database. Frequently used distinguished name elements include:

- uid (user identification)
- pw (password)
- cn (common name)
- ou (organizational unit)
- o (organization)
- c (country)

One way to test this is with a text-based LDAP client program. For example, OpenLDAP includes a client, `ldapsearch`, that you can use for this purpose.

Enter the following at the command line:

```
ldapsearch -x '(objectclass=*)'
```

The output is lengthy, but the information you need is in the first few lines:

```
version: 2
#
# filter: (objectclass=*)
# requesting: ALL

dn: dc=example,dc=com
dc: example
objectClass: top
objectClass: domain

dn: ou=People,dc=example,dc=com
ou: People
objectClass: top
objectClass: organizationalUnit
...
dn: uid=tbrown,ou=People,dc=example,dc=com
uid: tbrown
cn: Tom Brown
```

In the output above, you can see `tbrown` (uid) and `Tom Brown` (cn). Also note the dn is `ou=People, dc=example, dc=com`.

Configuring the FortiGate unit to use an LDAP server

After you determine the common name and distinguished name identifiers and the domain name or IP address of the LDAP server, you can configure the server on the FortiGate unit. The maximum number of remote LDAP servers that can be configured is 10.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see [Local and remote users on page 182](#).

To configure the FortiGate unit for LDAP authentication - web-based manager:

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter a **Name** for the LDAP server.
3. In **Server Name/IP** enter the server's FQDN or IP address.
4. If necessary, change the **Server Port** number. The default is port 389.
5. Enter the **Common Name Identifier** (20 characters maximum).
`cn` is the default, and is used by most LDAP servers.
6. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.
The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.
If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field.
See [Using the query icon on page 167](#).
7. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.
The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.
If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field.
See [Using the query icon on page 167](#).
8. In **Bind Type**, select **Regular**.
9. In **User DN**, enter the LDAP administrator's distinguished name.
10. In **Password**, enter the LDAP administrator's password.
11. Select **OK**.

To verify your Distinguished Name field is correct, you can select the **Test** button. If your DN field entry is valid, you will see the part of the LDAP database it defines. If your DN field entry is not valid, it will display an error message and return no information.

For detailed information about configuration options for LDAP servers, see the Online Help on your FortiGate unit or the FortiGate CLI Reference.

To configure the FortiGate unit for LDAP authentication - CLI example:

```
config user ldap
  edit ourLDAPsrv
    set server 10.11.101.160
    set cnid cn
    set dn cn=users,dc=office,dc=example,dc=com
    set type regular
    set username cn=administrator,cn=users,dc=office,dc=example,dc=com
    set password w5AiGVMLkgyPQ
    set password-expiry-warning enable
    set password-renewal enable
  end
```

password-expiry-warning and password-renewal

In SSLVPN, when an LDAP user is connecting to the LDAP server it is possible for them to receive any pending password expiry or renewal warnings. When the password renewal or expiry warning exists, SSLVPN users will see a prompt allowing them to change their password.

`password-expiry-warning` allows FortiOS to detect from the OpenLDAP server when a password is expiring or has expired using server controls or error codes. Please note that this is currently not supported for Windows AD LDAP.

`password-renewal` allows FortiOS to perform the online LDAP password renewal operations the LDAP server expects.

On an OpenLDAP server, when a user attempts to logon with an expired password they are allowed to logon but only to change their password.

When changing passwords on a Windows AD system, the connection must be SSL-protected.

UPN processing method and filter name

The following CLI commands available under `config user ldap` allow you to keep or strip the domain string of userPrincipalName (UPN) in the token as well as the search name for this kind of UPN.

Principle name peer user mode was only supported with Windows AD, and `fnbamd` has a hard coded `UserAccountControl` when doing LDAP authentication. `UserAccountControl` is a Windows AD specific attribute which doesn't exist in FortiAuthenticator or OpenLDAP.

To make LDAP query more flexible with different LDAP server versions, `account-key-filter` has been introduced to replace `account-key-name`. Enter the UPN attribute as the filter.

CLI syntax:

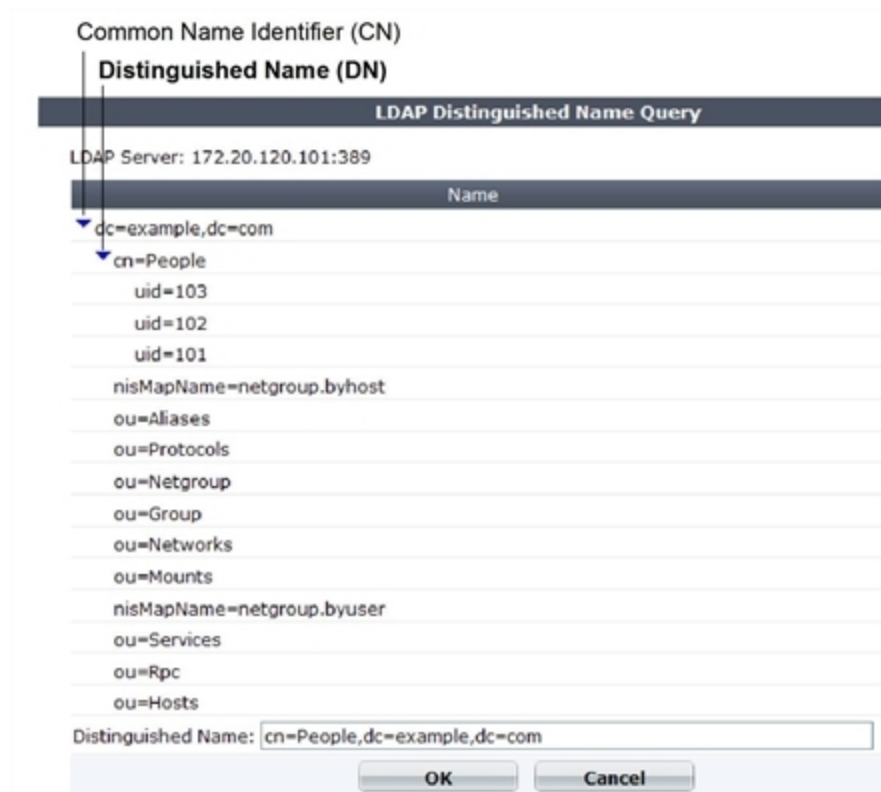

```
config user ldap
  set account-key-processing
  set account-key-filter
end
```

Using the query icon

The LDAP Distinguished Name Query list displays the LDAP directory tree for the LDAP server connected to the FortiGate unit. This helps you to determine the appropriate entry for the DN field. To see the distinguished name associated with the Common Name identifier, select the Expand icon next to the CN identifier. Select the DN from the list. The DN you select is displayed in the Distinguished Name field. Select OK and the Distinguished Name you selected will be saved in the Distinguished Name field of the LDAP Server configuration.

To see the users within the LDAP Server user group for the selected Distinguished Name, expand the Distinguished Name in the LDAP Distinguished Name Query tree.

LDAP server Distinguished Name Query tree

Non-blocking LDAP authentication

To support non-blocking LDAP authentication, fnbamd will create its own event-driven connection with LDAP servers over LDAP/LDAPS/STARTTLS, make it non-blocking, do CRL checking if necessary, and compose all LDAP requests using liblber (including bind, unbind, search, password renewal, password query, send request and receive response, and parse response). The whole process is done in one connection.

This doesn't change any openLDAP implementation but moves some data structure definitions and API definitions from some internal header files to public header files.

Example — wildcard admin accounts - CLI

A wildcard admin account is an administrator account with the wildcard option enabled. This option allows multiple different remote administration accounts to match one local administration account, avoiding the need to set up individual admin accounts on the FortiGate unit. Instead multiple LDAP admin accounts will all be able to use one FortiGate admin account.

The initial benefit of wildcard admin accounts is fast configuration of the FortiGate unit's administration account to work with your LDAP network. The many to one ratio saves on effort, and potential errors.

The ongoing benefit is that as long as the users on the LDAP system belong to that group, and the test admin user settings don't change on the FortiGate unit, no other work is required. This point is important as it can help avoid system updates or changes that would otherwise require changes to the LDAP administrator account

configuration. Even if a user is added to or removed from the LDAP group, no changes are required on the FortiGate unit.

Two potential issues with wildcard admin accounts are that multiple users may be logged on to the same account at the same time. This becomes an issue if they are changing the same information at the same time. The other potential issue is that security is reduced because multiple people have login access for the same account. If each user was assigned their own account, a hijacking of one account would not affect the other users.

Note that wildcard admin configuration also applies to RADIUS. When configuring for RADIUS, configure the RADIUS server, and RADIUS user group instead of LDAP. When using web-based management, wildcard admin is the only type of remote administrator account that does not require you to enter a password on account creation. That password is normally used when the remote authentication server is unavailable during authentication.

In this example, default values are used where possible. If a specific value is not mentioned, it is set to its default value.

Configuring the LDAP server

The important parts of this configuration are the username and group lines. The username is the domain administrator account. The group binding allows only the group with the name `GRP` to access.

The `dn` used here is as an example only. On your network use your own domain name.

To configure LDAP server - CLI:

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=example,DC=com,DC=au"
    set type regular
    set username "CN=Administrator,CN=Users,DC=example,DC=COM"
    set password *
    set group-member-check group-object
    set group-object-filter (&
      (objectcategory=group)member="CN=GRP,OU=training,DC=example,DC=COM")
  next
end
```

To configure the user group and add the LDAP server - CLI:

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap_server"
        set group-name "CN=GRP,OU=training,DC=example,DC=COM"
      next
    end
  next
end
```

Configuring the admin account

The wildcard part of this example is only available in the CLI for admin configuration. When enabled, this allows all LDAP group members to login to the FortiGate unit without the need to create a separate admin account for each user. In effect the members of that group will each be able to login as “test”.

To configure the admin account - CLI:

```
config system admin
  edit "test"
    set remote-auth enable
    set accprofile "super_admin"
    set wildcard enable
    set remote-group "ldap_grp"
  next
end
```

For troubleshooting, test that the admin account is operational, and see [Troubleshooting LDAP on page 171](#).

Example of LDAP to allow dial-in through member-attribute - CLI

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to setup a VPN connection simply based on an attribute that is set to TRUE, instead of based on being part of a specific group.

In AD, the “Allow Dial-In” property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to “TRUE”.

This same procedure can be used for other member attributes, as your system requires.

Configuring LDAP member-attribute settings

To accomplish this with a FortiGate unit, the member attribute must be set. Setting member attributes can only be accomplished through the CLI using the `member-attr` keyword - the option is not available through the web-based manager.

Before configuring the FortiGate unit, the AD server must be configured and have the `msNPAllowDialin` attribute set to “TRUE” for the users in question. If not, those users will not be able to properly authenticate.

The dn used here is as an example only. On your network use your own domain name.

To configure user LDAP member-attribute settings - CLI:

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=fortinet,DC=com,DC=au"
    set type regular
    set username "fortigate@example.com"
    set password *****
    set member-attr "msNPAllowDialin"
  next
end
```

Configuring LDAP group settings

A user group that will use LDAP must be configured. This example adds the member `ldap` to the group which is the LDAP server name that was configured earlier.

To configure LDAP group settings - CLI:

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
    edit 1
      set server-name "ldap"
      set group-name "TRUE"
    next
  end
end
```

Once these settings are in place, users can authenticate.

Troubleshooting LDAP

The examples in this section use the values from the previous example.

LDAP user test

A quick way to see if the LDAP configuration is correct is to run a `diagnose CLI` command with LDAP user information. The following command tests with a user called `netAdmin` and a password of `fortinet`. If the configuration is correct the test will be successful.

```
FGT# diag test authserver ldap ldap_server netAdmin fortinet
```

'ldap_server' is not a valid ldap server name — an LDAP server by that name has not been configured on the FortiGate unit, check your spelling.

authenticate 'netAdmin' against 'ldap_server' failed! — the user `netAdmin` does not exist on `ldap_server`, check your spelling of both the user and sever and ensure the user has been configured on the FortiGate unit.

LDAP authentication debugging

For a more in-depth test, you can use a `diag debug` command. The sample output from a shows more information about the authentication process that may prove useful if there are any problems.

Ensure the “Allow Dial-in” attribute is still set to “TRUE” and run the following CLI command. `fnbamd` is the Fortinet non-blocking authentication daemon.

```
FGT# diag debug enable
FGT# diag debug reset
FGT# diag debug application fnbamd -1
FGT# diag debug enable
```

The output will look similar to:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
```

```
get_member_of_groups-val[0]='TRUE'  
fnbamd_ldap_get_result-Auth accepted  
fnbamd_ldap_get_result-Going to DONE state res=0  
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS  
fnbamd_auth_poll_ldap-Passed group matching
```

If the “Allow Dial-in” attribute is not set but it is expected, the last line of the above output will instead be:

```
fnbamd_auth_poll_ldap-Failed group matching
```

TACACS+ servers

When users connect to their corporate network remotely, they do so through a remote access server. As remote access technology has evolved, the need for security when accessing networks has become increasingly important. This need can be filled using a Terminal Access Controller Access-Control System (TACACS+) server.

TACACS+ is a remote authentication protocol that provides access control for routers, network access servers, and other networked computing devices via one or more centralized servers. TACACS+ allows a client to accept a username and password and send a query to a TACACS+ authentication server. The server host determines whether to accept or deny the request and sends a response back that allows or denies the user access to the network.

TACACS+ offers fully encrypted packet bodies, and supports both IP and AppleTalk protocols. TACACS+ uses TCP port 49, which is seen as more reliable than RADIUS’s UDP protocol.

There are several different authentication protocols that TACACS+ can use during the authentication process:

Authentication protocols

Protocol	Definition
ASCII	Machine-independent technique that uses representations of English characters. Requires user to type a username and password that are sent in clear text (unencrypted) and matched with an entry in the user database stored in ASCII format.
PAP	Password Authentication Protocol (PAP) Used to authenticate PPP connections. Transmits passwords and other user information in clear text.
CHAP	Challenge-Handshake Authentication Protocol (CHAP) Provides the same functionality as PAP, but is more secure as it does not send the password and other user information over the network to the security server.
MS-CHAP	MicroSoft Challenge-Handshake Authentication Protocol v1 (MSCHAP) Microsoft-specific version of CHAP.
default	The default protocol configuration, Auto, uses PAP, MS-CHAP, and CHAP, in that order.

Configuring a TACACS+ server on the FortiGate unit

A maximum of 10 remote TACACS+ servers can be configured for authentication.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see [Local and remote users on page 182](#).

The TACACS+ page in the web-based manager (**User & Device > TACACS+ Servers**) is not available until a TACACS+ server has been configured in the CLI. For more information see the CLI Reference.

To configure the FortiGate unit for TACACS+ authentication - web-based manager:

1. Go to **User & Device > TACACS+ Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter the name of the TACACS+ server.
Server Name/IP	Enter the server domain name or IP address of the TACACS+ server.
Server Key	Enter the key to access the TACACS+ server.
Authentication Type	Select the authentication type to use for the TACACS+ server. Auto tries PAP, MSCHAP, and CHAP (in that order).

To configure the FortiGate unit for TACACS+ authentication - CLI:

```
config user tacacs+
  edit "TACACS-SERVER"
    set server [IP_ADDRESS]
    set key [PASSWORD]
    set authen-type ascii
  next
end
config user group
  edit "TACACS-GROUP"
    set group-type firewall
    set member "TACACS-SERVER"
  next
end
config system admin
  edit TACACS-USER
    set remote-auth enable
    set accprofile "super_admin"
    set vdom "root"
    set wildcard enable
    set remote-group "TACACS-GROUP"
  next
end
```

IPv6 TACACS+ server IP address

IPv6 address support is available for TACACS+ servers.

Syntax

```
config user tacacs+
  edit <name>
    set server <ipv6 address>
    set source-ipv6 <ipv6 address>
  next
```

```
end
```

POP3 servers

FortiOS can authenticate users who have accounts on POP3 or POP3s email servers. POP3 authentication can be configured only in the CLI.

To configure the FortiGate unit for POP3 authentication:

```
config user pop3
  edit pop3_server1
    set server pop3.fortinet.com
    set secure starttls
    set port 110
  end
```

To configure a POP3 user group:

```
config user group
  edit pop3_grp
    set member pop3_server1
  end
```

A user group can list up to six POP3 servers as members.

SSO servers

Novell and Microsoft Windows networks provide user authentication based on directory services: eDirectory for Novell, Active Directory for Windows. Users can log on at any computer in the domain and have access to resources as defined in their user account. The Fortinet Single Sign On (FSSO) agent enables FortiGate units to authenticate these network users for security policy or VPN access without asking them again for their username and password.

When a user logs in to the Windows or Novell domain, the FSSO agent sends to the FortiGate unit the user's IP address and the names of the user groups to which the user belongs. The FortiGate unit uses this information to maintain a copy of the domain controller user group database. Because the domain controller authenticates users, the FortiGate unit does not perform authentication. It recognizes group members by their IP address.

In the FortiOS FSSO configuration, you specify the server where the FSSO Collector agent is installed. The Collector agent retrieves the names of the Novell or Active Directory user groups from the domain controllers on the domains, and then the FortiGate unit gets them from the Collector agent. You cannot use these groups directly. You must define FSSO type user groups on your FortiGate unit and then add the Novell or Active Directory user groups to them. The FSSO user groups that you created are used in security policies and VPN configurations to provide access to different services and resources.

FortiAuthenticator servers can replace the Collector agent when FSSO is using polling mode. The benefits of this is that FortiAuthenticator is a stand-alone server that has the necessary FSSO software pre-installed. For more information, see the [FortiAuthenticator Administration Guide](#).

SSO agent configuration settings

The following are SSO configuration settings in **Security Fabric > Fabric Connectors**.

SSO server List

Lists all the collector agents' lists that you have configured (along with other Security Fabric connectors). On this page, you can create, edit or delete FSSO agents. There are different types of FSSO agents, each with its own settings.

You can create a redundant configuration on your unit if you install a collector agent on two or more domain controllers. If the current (or first) collector agent fails, the Fortinet unit switches to the next one in its list of up to five collector agents.

Create New	Gives you the option to create a new agent. When you select Create New , you are automatically redirected to the New Fabric Connector page. Select an option from under SSO/Identity .
Edit	<p>Modifies the settings for the selected SSO server.</p> <p>To remove multiple entries from the list, for each servers you want removed, select the check box and then select Delete.</p> <p>To remove all agents from the list, on the FSSO Agent page, select the check box at the top of the check box column and then select Delete.</p>
Delete	Removes an agent from the list on the page.

Settings for Poll Active Directory Server

Server IP/Name	The IP address of the domain controller (DC).
User	The user ID used to access the domain controller.
Password	Enter the password for the account used to access the DC.
LDAP Server	Select the check box and select an LDAP server to access the Directory Service.
Enable Polling	Enable to allow the FortiGate unit to poll this DC.
Users/Groups	A list of user and user group names retrieved from the DC.

Settings when Type is RADIUS Single Sign On Agent

Name	Enter a name for the SSO server.
Use RADIUS Shared Secret	Enable and specify the SSO server secret.
Send RADIUS Responses	Enable to send RADIUS responses.

Settings for Fortinet Single Sign On Agent

Name	Enter a name for the SSO server.
Primary FSSO Agent	Enter the IP address or name of the Directory Service server where this SSO agent is installed, along with the password. The maximum number of characters is 63.
FSSO Agent	Optionally, add and configured up to four additional FSSO agents, up to a maximum of five.
Collector Agent AD access mode	Select one of the following options: <ul style="list-style-type: none"> • Standard: Enable and view A list of user and user group names retrieved from the server. • Advanced: Enable and select an LDAP server to access the Directory Service.

RSA ACE (SecurID) servers

SecurID is a two-factor system that uses one-time password (OTP) authentication. It is produced by the company RSA. This system includes portable tokens carried by users, an RSA ACE/Server, and an Agent Host. In our configuration, the FortiGate unit is the Agent Host.

Components

When using SecurID, users carry a small device or “token” that generates and displays a pseudo-random password. According to RSA, each SecurID authenticator token has a unique 64-bit symmetric key that is combined with a powerful algorithm to generate a new code every 60 seconds. The token is time-synchronized with the SecurID RSA ACE/Server.

The RSA ACE/Server is the management component of the SecurID system. It stores and validates the information about the SecurID tokens allowed on your network. Alternately the server could be an RSA SecurID 130 Appliance.

The Agent Host is the server on your network, in this case it is the FortiGate unit, that intercepts user logon attempts. The Agent Host gathers the user ID and password entered from their SecurID token, and sends that information to the RSA ACE/Server to be validated. If valid, a reply comes back indicating it is a valid logon and the FortiGate unit allows the user access to the network resources specified in the associated security policy.

Configuring the SecurID system

To use SecurID with a FortiGate unit, you need:

- to configure the RSA server and the RADIUS server to work with each other (see RSA server documentation)
- [to configure the RSA SecurID 130 Appliance](#)
- or
- [to configure the FortiGate unit as an Agent Host on the RSA ACE/Server](#)
- [to configure the FortiGate unit to use the RADIUS server](#)
- [to create a SecurID user group](#)
- [to configure a security policy with SecurID authentication](#)

The following instructions are based on RSA ACE/Server version 5.1, or RSA SecurID 130 Appliance, and assume that you have successfully completed all the external RSA and RADIUS server configuration steps listed above.

For this example, the RSA server is on the internal network, with an IP address of 192.128.100.100. The FortiGate unit internal interface address is 192.168.100.3, RADIUS shared secret is fortinet123, RADIUS server is at IP address 192.168.100.102.

To configure the RSA SecurID 130 appliance

1. Go to the IMS Console for SecurID and logon.
2. Go to **RADIUS > RADIUS Clients**, and select **Add New**.
3. Enter the following information to configure your FortiGate as a SecurID Client, and select Save.

RADIUS Client Basics	
Client Name	FortiGate
Associated RSA Agent	FortiGate
RADIUS Client Settings	
IP Address	192.168.100.3 The IP address of the FortiGate unit internal interface.
Make / Model	Select Standard Radius
Shared Secret	fortinet123 The RADIUS shared secret.
Accounting	Leave unselected
Client Status	Leave unselected

To configure the FortiGate unit as an Agent Host on the RSA ACE/Server

1. On the RSA ACE/Server computer, go to **Start > Programs > RSA ACE/Server**, and then **Database Administration - Host Mode**.
2. On the **Agent Host** menu, select **Add Agent Host**.
3. Enter and save the following information.

Name	FortiGate
Network Address	192.168.100.3 The IP address of the FortiGate unit.
Secondary Nodes	Optionally enter other IP addresses that resolve to the FortiGate unit.

If needed, refer to the RSA ACE/Server documentation for more information.

To configure the FortiGate unit to use the RADIUS server

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	RSA
Primary Server IP/Name	192.168.100.102 Optionally select Test to ensure the IP address is correct and the FortiGate can contact the RADIUS server.
Primary Server Secret	fortinet123
Authentication Scheme	Select Use Default Authentication Scheme .

To create a SecurID user group

1. Go to **User & Device > User Groups**, and select **Create New**.
2. Enter the following information.

Name	RSA_group
Type	Firewall

3. In **Remote Groups**, select **Add**, then select the RSA server.
4. Select **OK**.

To create a SecurID user:

1. Go to **User & Device > User Definition**, and select **Create New**.
2. Use the wizard to enter the following information, and then select **Create**.

User Type	Remote RADIUS User
User Name	wloman
RADIUS Server	RSA
Contact Info	(optional) Enter Email or SMS information
User Group	RSA_group

To test this configuration, on your FortiGate unit use the CLI command:

```
diagnose test authserver radius RSA auto wloman 111111111
```

The series of 1s is the one time password that your RSA SecurID token generates and you enter.

Using the SecurID user group for authentication

You can use the SecurID user group in several FortiOS features that authenticate by user group including

- [Security policy](#)
- [IPsec VPN XAuth](#)
- [PPTP VPN](#)
- [SSL VPN](#)

The following sections assume the SecurID user group is called `securIDgrp` and has already been configured. Unless otherwise states, default values are used.

Security policy

To use SecurID in a security policy, you must include the SecurID user group in a security policy. This procedure will create a security policy that allows HTTP, FTP, and POP3 traffic from the `internal` interface to `wan1`. If these interfaces are not available on your FortiGate unit, substitute other similar interfaces.

To configure a security policy with SecurID authentication

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter:

Incoming Interface	internal
Source Address	all
Source User(s)	securIDgrp
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Services	HTTP, FTP, POP3
Action	ACCEPT
NAT	On
Shared Shaper	On, if you want to either limit traffic or guarantee minimum bandwidth for traffic that uses the SecurID security policy. Use the default shaper guarantee-100kbps .
Log Allowed Traffic	On, if you want to generate usage reports on traffic authenticated with this policy.

4. Select **OK**.
The SecurID security policy is configured.

For more detail on configuring security policies, see the FortiOS Handbook FortiGate Fundamentals guide.

IPsec VPN XAuth

Extended Authentication (XAuth) increases security by requiring user authentication in addition to the pre-shared key.

When creating an IPsec VPN using the wizard, under **VPN > IPsec Wizard**, select the SecurID **User Group** on the Authentication page. Members of the SecurID group are required to enter their SecureID code to authenticate.

For more on XAuth, see [Configuring XAuth authentication on page 230](#)

PPTP VPN

PPTP VPN is configured in the CLI. In the PPTP configuration (`config vpn pptp`), set `usrgrp` to the SecurID user group.

SSL VPN

You need to map the SecurID user group to the portal that will serve SecurID users and include the SecurID user group in the **Source User(s)** field in the security policy.

To map the SecurID group to an SSL VPN portal:

1. Go to **VPN > SSL-VPN Settings**.
2. In **Authentication/Portal Mapping**, select **Create New**.
3. Enter

Users/Groups	securIDgrp
Portal	Choose the portal.

4. Select **OK**.

Users and user groups

FortiGate authentication controls system access by user group. By assigning individual users to the appropriate user groups you can control each user's access to network resources. The members of user groups are user accounts, of which there are several types. Local users and peer users are defined on the FortiGate unit. User accounts can also be defined on remote authentication servers.

This section describes how to configure local users and peer users and then how to configure user groups. For information about configuration of authentication servers see [Authentication servers on page 155](#).

This section contains the following topics:

- [Users](#)
- [User groups](#)

Users

A user is a user account consisting of username, password, and in some cases other information, configured on the FortiGate unit or on an external authentication server. Users can access resources that require authentication only if they are members of an allowed user group. There are several different types of user accounts with slightly different methods of authentication:

User type	Authentication
Local user	The username and password must match a user account stored on the FortiGate unit. Authentication by FortiGate security policy.
Remote user	The username must match a user account stored on the FortiGate unit and the username and password must match a user account stored on the remote authentication server. FortiOS supports LDAP, RADIUS, and TACACS+ servers.
Authentication server user	A FortiGate user group can include user accounts or groups that exist on a remote authentication server.
FSSO user	With Fortinet Single Sign On (FSSO), users on a Microsoft Windows or Novell network can use their network authentication to access resources through the FortiGate unit. Access is controlled through FSSO user groups which contain Windows or Novell user groups as their members.
PKI or Peer user	A Public Key Infrastructure (PKI) or peer user is a digital certificate holder who authenticates using a client certificate. No password is required, unless two-factor authentication is enabled.
IM Users	IM users are not authenticated. The FortiGate unit can allow or block each IM user name from accessing the IM protocols. A global policy for each IM protocol governs access to these protocols by unknown users.
Guest Users	Guest user accounts are temporary. The account expires after a selected period of time.

This section includes:

- [Local and remote users](#)
- [PKI or peer users](#)
- [Two-factor authentication](#)
- [FortiToken](#)
- [Monitoring users](#)

Local and remote users

Local and remote users are defined on the FortiGate unit in **User & Device > User Definition**.

Create New	Creates a new user account. When you select Create New , you are automatically redirected to the User Creation Wizard.
Edit User	Modifies a user's account settings. When you select Edit , you are automatically redirected to the Edit User page.
Delete	<p>Removes a user from the list. Removing the user name removes the authentication configured for the user.</p> <p>The Delete icon is not available if the user belongs to a user group.</p> <p>To remove multiple local user accounts from within the list, on the User page, in each of the rows of user accounts you want removed, select the check box and then select Delete.</p> <p>To remove all local user accounts from the list, on the User page, select the check box in the check box column and then select Delete.</p>
User Name	The user name. For a remote user, this username must be identical to the username on the authentication server.
Type	Local indicates a local user authenticated on the FortiGate unit. For remote users, the type of authentication server is shown: LDAP, RADIUS, or TACACS+.
Two-factor Authentication	Indicates whether two-factor authentication is configured for the user.
Ref.	<p>Displays the number of times this object is referenced by other objects. Select the number to open the Object Usage window and view the list of referring objects. The list is grouped into expandable categories, such as Firewall Policy. Numbers of objects are shown in parentheses.</p> <p>To view more information about the referring object, use the icons:</p> <ul style="list-style-type: none"> • View the list page for these objects – available for object categories. Goes to the page where the object is listed. For example, if the category is User Groups, opens User Groups list. • Edit this object – opens the object for editing. • View the details for this object – displays current settings for the object.

To create a local or remote user account - web-based manager:

1. Go to **User & Device > User Definition** and select **Create New**.
2. On the **Choose User Type** page select:

Local User	Select to authenticate this user using a password stored on the FortiGate unit.
Remote RADIUS User Remote TACACS+ User Remote LDAP User	To authenticate this user using a password stored on an authentication server, select the type of server and then select the server from the list. You can select only a server that has already been added to the FortiGate unit configuration.

3. Select **Next** and provide user authentication information.
For a local user, enter the **User Name** and **Password**.
For a remote user, enter the **User Name** and the server name.
4. Select **Next** and enter **Contact Information**.
If email or SMS is used for two-factor authentication, provide the email address or SMS cell number at which the user will receive token password codes. If a custom SMS service is used, it must already be configured. See [FortiToken on page 188](#).
5. Select **Next**, then on the **Provide Extra Info** page enter

Two-factor Authentication	Select to enable two-factor authentication. Then select the Token (FortiToken or FortiToken Mobile) for this user account. See Associating FortiTokens with accounts on page 192 .
User Group	Select the user groups to which this user belongs.

6. Select **Create**.

To create a local user - CLI example:

Locally authenticated user

```
config user local
  edit user1
    set type password
    set passwd ljt_pj2gpepfdw
  end
```

To create a remote user - CLI example:

```
config user local
  edit user2
    set type ldap
    set ldap_server ourLDAPsrv
  end
```

For a RADIUS or TACACS+ user, set `type` to `radius` or `tacacs+`, respectively.

To create a user with FortiToken Mobile two-factor authentication - CLI example:

```
config user local
  edit user5
    set type password
    set passwd ljt_pj2gpepfdw
    set two_factor fortitoken
    set fortitoken 182937197
  end
```

Remote users are configured for FortiToken two-factor authentication similarly.

To create a user with SMS two-factor authentication using FortiGuard messaging service - CLI example:

```
config user local
  edit user6
    set type password
    set passwd 3ww_pjt68dw
    set two_factor sms
    set sms-server fortiguard
    set sms-phone 1365984521
  end
```

Removing users

Best practices dictate that when a user account is no longer in use, it should be deleted. Removing local and remote users from FortiOS involve the same steps.

If the user account is referenced by any configuration objects, those references must be removed before the user can be deleted. See [Removing references to users on page 184](#).

To remove a user from the FortiOS configuration - web-based manager:

1. Go to **User & Device > User Definition**.
2. Select the check box of the user that you want to remove.
3. Select **Delete**.
4. Select **OK**.

To remove a user from the FortiOS configuration - CLI example:

```
config user local
  delete user4444
end
```

Removing references to users

You cannot remove a user that belongs to a user group. Remove the user from the user group first, and then delete the user.

To remove references to a user - web-based manager

1. Go to **User & Device > User Definition**.
2. If the number in the far right column for the selected user contains any number other than zero, select it.

3. A more detailed list of object references to this user is displayed. Use its information to find and remove these references to allow you to delete this user.

PKI or peer users

A PKI, or peer user, is a digital certificate holder. A PKI user account on the FortiGate unit contains the information required to determine which CA certificate to use to validate the user's certificate. Peer users can be included in firewall user groups or peer certificate groups used in IPsec VPNs. For more on certificates, see [Certificates overview on page 242](#).

To define a peer user you need:

- a peer username
- the text from the subject field of the user's certificate, or the name of the CA certificate used to validate the user's certificate

Creating a peer user

The peer user can be configured only in the CLI.

To create a peer user for PKI authentication - CLI example:

```
config user peer
  edit peer1
    set subject peer1@mail.example.com
    set ca CA_Cert_1
  end
```

There are other configuration settings that can be added or modified for PKI authentication. For example, you can configure the use of an LDAP server to check access rights for client certificates. For information about the detailed PKI configuration settings, see the FortiGate CLI Reference.

Two-factor authentication

The standard logon requires a username and password. This is one factor authentication—your password is one piece of information you need to know to gain access to the system.

Two factor authentication adds the requirement for another piece of information for your logon. Generally the two factors are something you know (password) and something you have (certificate, token, etc.). This makes it harder for a hacker to steal your logon information. For example if you have a FortiToken device, the hacker would need to both use it and know your password to gain entry to your account.

Two-factor authentication is available on both user and admin accounts. But before you enable two-factor authentication on an administrator account, you need to ensure you have a second administrator account configured to guarantee administrator access to the FortiGate unit if you are unable to authenticate on the main admin account for some reason.

Two-factor authentication does not work with explicit proxies.

FortiToken extension to comply with PCI 3.2

With `multi-factor-authentication` enabled as `mandatory` (see syntax below), all authentication will collect both username/password and OTP as a second factor before presenting an authentication result. The system will log for each factor.

If a user is not configured with two-factor authentication, any OTP or an empty OTP would make the second factor authentication pass.

FortiOS processes the user and password first and then always collects the second factor (if configured) without any indication of the first factor failing or succeeding. FortiOS accepts the second factor even if the first failed (unknown to the user) and returns a login attempt pass or fail, with no indication of which factor failed.

Syntax

```
config system global
  set multi-factor-authentication {optional | mandatory}
end
```

The methods of two-factor authentication include:

- [Certificate](#)
- [Email](#)
- [SMS](#)
- [FortiToken](#)

Certificate

You can increase security by requiring both certificate and password authentication for PKI users. Certificates are installed on the user's computer. Requiring a password also protects against unauthorized use of that computer.

Optionally peer users can enter the code from their FortiToken instead of the certificate.

To create a peer user with two-factor authentication - CLI example

```
config user peer
  edit peer1
    set subject E=peer1@mail.example.com
    set ca CA_Cert_1
    set two-factor enable
    set passwd fdktguefheygfe
  end
```

For more information on certificates, see [Certificates overview on page 242](#).

Email

Two-factor email authentication sends a randomly generated six digit numeric code to the specified email address. Enter that code when prompted at logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted.

A benefit is that you do not require mobile service to authenticate. However, a potential issue is if your email server does not deliver the email before the 60 second life of the token expires.

The code will be generated and emailed at the time of logon, so you must have email access at that time to be able to receive the code.

To configure an email provider - web-based manager:

1. Go to **System > Advanced** and enable **Use Custom Email Server** under **Email Service**.
2. Enter **SMTP Server** and **Default Reply To** address.
3. If applicable, enable **Authentication** and enter the **SMTP User** and **Password** to use.
4. Select a **Security Mode**, options are: **None**, **SMTPS** or **STARTTLS**.
5. Enter the **Port** number, the default is 25.
6. Select **Apply**.

To configure an email provider - CLI:

```
config system email-server
    set server <server_domain-name>
    set reply-to <Recipient_email_address>
end
```

To enable email two-factor authentication - web-based manager:

1. To modify an administrator account, go to **System > Administrators**. To modify a user account go to **User & Device > User Definition**.
2. Edit the user account.
3. Enable and enter the user's **Email Address**.
4. Select **Enable Two-factor Authentication**.
5. Select **Email based two-factor authentication**.
6. Select **OK**.

If **Email based two-factor authentication** option doesn't appear after selecting **Enable Two-factor Authentication**, you need to enable it via the CLI as follows.

To enable email two-factor authentication - CLI:

```
config user local
    edit <user_name>
        set email-to <user_email>
        set two-factor email
    end
```

SMS

SMS two-factor authentication sends the token code in an SMS text message to the mobile device indicated when this user attempts to logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted. Enter this code when prompted at logon to be authenticated.

SMS two-factor authentication has the benefit that you do not require email service before logging on. A potential issue is if the mobile service provider does not send the SMS text message before the 60 second life of the token expires.

FortiGuard Messaging Service include four SMS Messages at no cost. If you need more, you should acquire a license through support.fortinet.com or via customer service.

If you do not use the FortiGuard Messaging Service, you need to configure an SMS service.

To configure an SMS service - CLI:

```
config system sms-server
  edit <provider_name>
    set mail-server <server_domain-name>
  next
end
```

To configure SMS two-factor authentication - web-based manager:

1. To modify an:
 - administrator account, go to **System > Administrators**, or
 - user account go to **User & Device > User Definition**.
2. Edit the user account.
3. Select **SMS** and enter the **Country Dial Code** and **Phone Number**.
4. Select **Enable Two-factor Authentication**, and select the correct **Token**.
5. Select **OK**.

If you have problems receiving the token codes via SMS messaging, contact your mobile provider to ensure you are using the correct phone number format to receive text messages and that your current mobile plan allows text messages.

FortiToken

FortiToken is a disconnected one-time password (OTP) generator. It is a small physical device with a button that when pressed displays a six digit authentication code. This code is entered with a user's username and password as two-factor authentication. The code displayed changes every 60 seconds, and when not in use the LCD screen is blanked to extend the battery life.

There is also a mobile phone application, FortiToken Mobile, that performs much the same function.

FortiTokens have a small hole in one end. This is intended for a lanyard to be inserted so the device can be worn around the neck, or easily stored with other electronic devices. Do not put the FortiToken on a key ring as the metal ring and other metal objects can damage it. The FortiToken is an electronic device like a cell phone and must be treated with similar care.

Any time information about the FortiToken is transmitted, it is encrypted. When the FortiGate unit receives the code that matches the serial number for a particular FortiToken, it is delivered and stored encrypted. This is in keeping with the Fortinet's commitment to keeping your network highly secured.

FortiTokens can be added to user accounts that are local, IPsec VPN, SSL VPN, and even Administrators. See [Associating FortiTokens with accounts on page 192](#).

A FortiToken can be associated with only one account on one FortiGate unit.

If a user loses their FortiToken, it can be locked out using the FortiGate so it will not be used to falsely access the network. Later if found, that FortiToken can be unlocked on the FortiGate to allow access once again. See [FortiToken maintenance on page 194](#).

There are three tasks to complete before FortiTokens can be used to authenticate accounts:

1. [Adding FortiTokens to the FortiGate](#)
2. [Activating a FortiToken on the FortiGate](#)
3. [Associating FortiTokens with accounts](#)

In addition, this section includes the following:

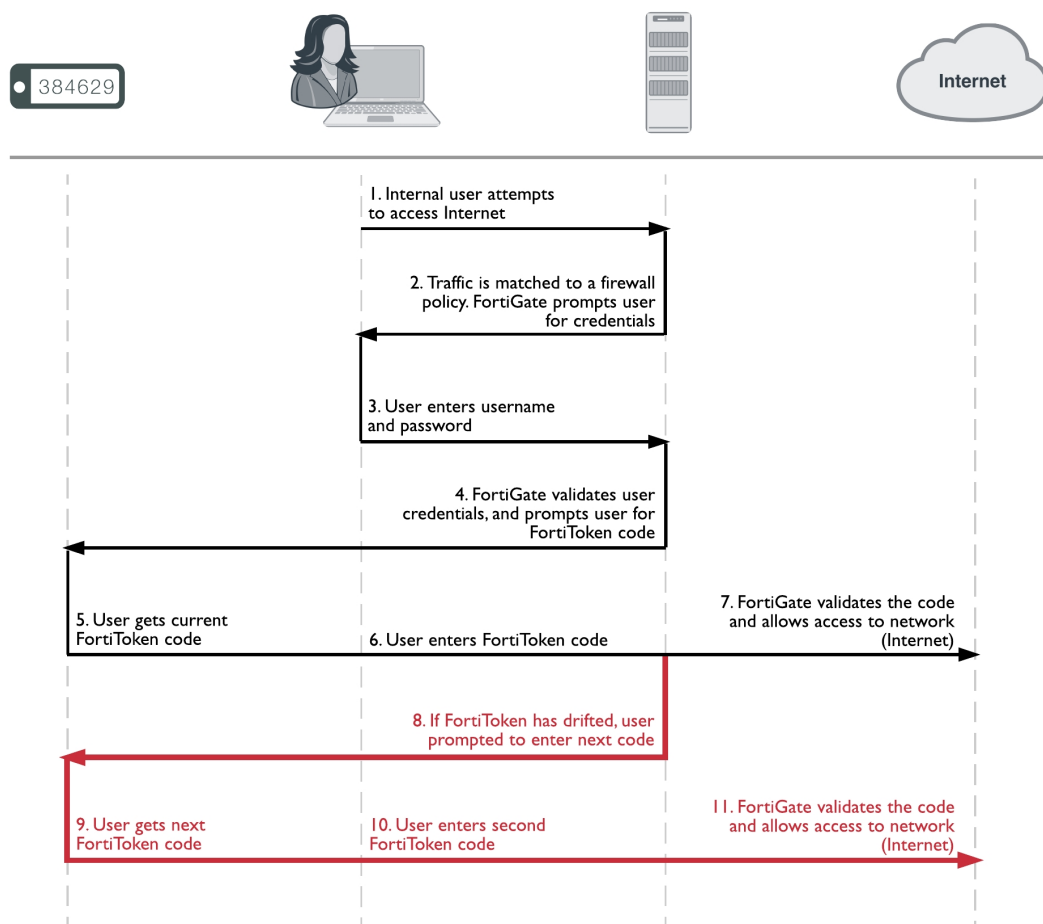

- [FortiToken maintenance](#)
- [FortiToken Mobile Push](#)

The FortiToken authentication process

The steps during FortiToken two-factor authentication are as follows.

1. User attempts to access a network resource.
2. FortiGate unit matches the traffic to an authentication security policy, and FortiGate unit prompts the user for username and password.
3. User enters their username and password.
4. FortiGate unit verifies their information, and if valid prompts the user for the FortiToken code.
5. User gets the current code from their FortiToken device.
6. User enters current code at the prompt.
7. FortiGate unit verifies the FortiToken code, and if valid allows access to the network resources such as the Internet.
The following steps are needed only if the time on the FortiToken has drifted and needs to be re-synchronized with the time on the FortiGate unit.
8. If time on FortiToken has drifted, FortiGate unit will prompt user to enter a second code to confirm.
9. User gets the next code from their FortiToken device
10. User enters the second code at the prompt.
11. FortiGate unit uses both codes to update its clock to match the FortiToken and then proceeds as in step "[Users and user groups](#)" on page 181.

The FortiToken authentication process is illustrated below:

When configured the FortiGate unit accepts the username and password, authenticates them either locally or remotely, and prompts the user for the FortiToken code. The FortiGate then authenticates the FortiToken code. When FortiToken authentication is enabled, the prompt field for entering the FortiToken code is automatically added to the authentication screens.

Even when an Administrator is logging in through a serial or Telnet connection and their account is linked to a FortiToken, that Administrator will be prompted for the token's code at each login.

If you have attempted to add invalid FortiToken serial numbers, there will be no error message. The serial numbers will simply not be added to the list.

Adding FortiTokens to the FortiGate

Before one or more FortiTokens can be used to authenticate logons, they must be added to the FortiGate. The import feature is used to enter many FortiToken serial numbers at one time. The serial number file must be a text file with one FortiToken serial number per line.

Both FortiToken Mobile and physical FortiTokens store their encryption seeds on the cloud, therefore you will only be able to register them to a single FortiGate or FortiAuthenticator.

Because FortiToken-200CD seed files are stored on the CD, these tokens can be registered on multiple FortiGates and/or FortiAuthenticators, but **not** simultaneously.

To manually add a FortiToken to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token** or **Mobile Token**.
4. Enter one or more FortiToken serial numbers (hard token) or activation codes (mobile token).
5. Select **OK**.

For mobile token, you receive the activation code in the license certificate once you purchase a license. FortiOS include a license for two mobile token at no cost.

To import multiple FortiTokens to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token**.
4. Select **Import**.
5. Select **Serial Number File** or **Seed File**, depending on which file you have.
6. Browse to the local file location on your local computer.
7. Select **OK**.
The file is imported.
8. Select **OK**.

To import FortiTokens to the FortiGate from external sources - CLI:

FortiToken seed files (both physical and mobile versions) can be imported from either FTP or TFTP servers, or a USB drive, allowing seed files to be imported from an external source more easily:

```
execute fortitoken import ftp <file name> <ip>[:ftp port] <Enter> <user> <password>
execute fortitoken import tftp <file name> <ip>
execute fortitoken import usb <file name>
```

To import seed files for FortiToken Mobile, replace `fortitoken` with `fortitoken-mobile`.

To add two FortiTokens to the FortiGate - CLI:

```
config user fortitoken
  edit <serial_number>
```

```
next
edit <serial_number2>
next
end
```

Activating a FortiToken on the FortiGate

Once one or more FortiTokens have been added to the FortiGate unit, they must be activated before being available to be associated with accounts. The process of activation involves the FortiGate querying FortiGuard servers about the validity of each FortiToken. The serial number and information is encrypted before it is sent for added security.

A FortiGate unit requires a connection to FortiGuard servers to activate a FortiToken.

To activate a FortiToken on the FortiGate unit - web-based manager:

1. Go to **User & Device > FortiTokens**.
 2. Select one or more FortiTokens with a status of Available.
 3. Right-click the FortiToken entry and select **Activate**.
 4. Select **Refresh**.
- The status of selected FortiTokens will change to Activated.

The selected FortiTokens are now available for use with user and admin accounts.

To activate a FortiToken on the FortiGate unit - CLI:

```
config user fortitoken
edit <token_serial_num>
set status activate
next
end
```

Associating FortiTokens with accounts

The final step before using the FortiTokens to authenticate logons is associating a FortiToken with an account. The accounts can be local user or administrator accounts.

To add a FortiToken to a local user account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **User & Device > User Definition**, and edit the user account.
3. Enter the user's **Email Address**.
4. Enable **Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code** to be sent to the email address configured previously. The user will use this code to activate his mobile token. An **Email Service** has to be set under **System > Advanced** in order to send the activation code.

To add a FortiToken to a local user account - CLI:

```
config user local
  edit <username>
    set type password
    set passwd "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set email-to "username@example.com"
    set status enable
  next
end
```

To add a FortiToken to an administrator account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **System > Administrators**, and edit the admin account.
This account is assumed to be configured except for two-factor authentication.
3. Enter admin's **Email Address**.
4. Enable **Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code** to be sent to the email address configured previously. The admin will use this code to activate his mobile token. An **Email Service** has to be set under **System > Advanced** in order to send the activation code.

To add a FortiToken to an administrator account - CLI:

```
config system admin
  edit <username>
    set password "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set email-to "username@example.com"
  next
end
```

The `fortitoken` keyword will not be visible until `fortitoken` is selected for the `two-factor` option.

Before a new FortiToken can be used, it may need to be synchronized due to clock drift.

FortiToken maintenance

Once FortiTokens are entered into the FortiGate unit, there are only two tasks to maintain them — changing the status,

To change the status of a FortiToken between activated and locked - CLI:

```
config user fortitoken
  edit <token_serial_num>
    set status lock
  next
end
```

Any user attempting to login using this FortiToken will not be able to authenticate.

To list the drift on all FortiTokens configured on this FortiGate unit - CLI:

```
# diag fortitoken info
FORTITOKEN DRIFT STATUS
FTK2000BHV1KRZCC 0 token already activated, and seed won't be returned
FTK2001C5YCRRVEE 0 token already activated, and seed won't be returned
FTKMOB4B94972FBA 0 provisioned
FTKMOB4BA4BE9B84 0 new
Total activated token: 0
Total global activated token: 0
Token server status: reachable
```

This command lists the serial number and drift for each FortiToken configured on this FortiGate unit. This command is useful to check if it is necessary to synchronize the FortiGate and any particular FortiTokens.

FortiToken Mobile Push

A command under `config system ftm-push` allows you to configure the FortiToken Mobile Push services server IP address and port number. The Push service is provided by Apple (APNS) and Google (GCM) for iPhone and Android smartphones respectively. This will help to avoid tokens becoming locked after an already enabled two-factor authentication user has been disabled.

CLI syntax

```
config system ftm-push
  set server-ip <ip-address>
  set server-port [1-65535] Default is 4433.
end
```

Note that the `server-ip` is the public IP address of the FortiGate interface that the FTM will call back to; it is the IP address used by the FortiGate for incoming FTM calls.

If an SSL VPN user authenticates with their token, then logs out and attempts to reauthenticate again within a minute, a new message will display showing "Please wait x seconds to login again." This replaces a previous error/permission denied message.

The "x" value will depend on the calculation of how much time is left in the current time step.

CLI syntax

```
config system interface
edit <name>
set allowaccess ftm
next
end
```

FortiGate supports when the FortiAuthenticator initiates FTM Push notifications, for when users are attempting to authenticate through a VPN and/or RADIUS (with FortiAuthenticator as the RADIUS server).

Monitoring users

To monitor user activity in the web-based manager, go to **Monitor > Firewall User Monitor**. The list of users who are logged on is displayed with some information about them such as their user group, security policy ID, how long they have been logged on, their IP address, traffic volume, and their authentication method as one of FSSO, NTLM, or firewall (FW-auth).

From this screen you can de-authenticate all users who are logged on. The de-authenticate button is at the top left of this screen.

To see information about banned users go to **Monitor > Quarantine Monitor**. Displayed information about users who have been banned includes what application triggered the ban (Application Protocol), the reason for the ban (Cause or rule), Created, and when the ban expires.

Filtering the list of users

When there are many users logged on, it can be difficult to locate a specific user or multiple users to analyze. Applying filters to the list allows you to organize the user list to meet your needs, or only display some the users that meet your current requirements.

Select settings bottom at the top right of the screen to adjust columns that are displayed for users, including what order they are displayed in. This can be very helpful in locating information you are looking for.

Each column heading has a grey filter icon. Click on the filter icon to configure a filter for the data displayed in that column. Each column has similar options including a field to enter the filtering information, a check box to select the negative of the text in the field, and the options to add more fields, apply the filter, clear all filters, or cancel without saving. To enter multiple terms in the field, separate each of them with a comma. To filter entries that contain a specific prefix, use an * (asterisk).

For example, to create a filter to display only users with an IP address of 10.11.101.x who authenticated using one of security policies five through eight, and who belong to the user group Accounting.

1. Go to **Monitor > Quarantine Monitor**.
2. Enter 10.11.101.* and select **Apply**.
3. Select the filter icon beside **Policy ID**.
4. Enter 5-8 and select **Apply**.
5. Select the filter icon beside **User Group**.
6. Enter Accounting and select **Apply**.

**Login credentials for guest users shown in clear text on GUI and voucher**

In FortiOS 5.6.4, login credentials for guest users is displayed/printed in clear text on the GUI and in the voucher. It is also sent in clear text by SMS and email.

User groups

A user group is a list of user identities. An identity can be:

- a local user account (username/password stored on the FortiGate unit)
- a remote user account (password stored on a RADIUS, LDAP, or TACACS+ server)
- a PKI user account with digital client authentication certificate stored on the FortiGate unit
- a RADIUS, LDAP, or TACACS+ server, optionally specifying particular user groups on that server
- a user group defined on an FSSO server.

Security policies and some types of VPN configurations allow access to specified user groups only. This restricted access enforces Role Based Access Control (RBAC) to your organization's network and its resources. Users must be in a group and that group must be part of the security policy.

In most cases, the FortiGate unit authenticates users by requesting their username and password. The FortiGate unit checks local user accounts first. If a match is not found, the FortiGate unit checks the RADIUS, LDAP, or TACACS+ servers that belong to the user group. Authentication succeeds when a matching username and password are found. If the user belongs to multiple groups on a server, those groups will be matched as well.

FortiOS does not allow username overlaps between RADIUS, LDAP, or TACACS+ servers.

There are four types of FortiGate user groups: Firewall, FSSO, Guest, and RADIUS single sign-on (RSSO) user groups.

Firewall user groups

Firewall user groups are used locally as part of authentication. When a security policy allows access only to specified user groups, users must authenticate. If the user authenticates successfully and is a member of one of the permitted groups, the session is allowed to proceed.

This section includes:

- [SSL VPN access](#)
- [IPsec VPN access](#)
- [Configuring a firewall user group](#)
- [Multiple group enforcement support](#)
- [User group timeouts](#)

SSL VPN access

SSL VPN settings include a list of the firewall user groups that can access the SSL VPN and the SSL VPN portal that each group will use. When the user connects to the FortiGate unit via HTTPS on the SSL VPN port (default 10443), the FortiGate unit requests a username and password.

SSL VPN access also requires a security policy where the destination is the SSL interface. For more information, see the [FortiOS Handbook SSL VPN](#) guide.

IPsec VPN access

A firewall user group can provide access for dialup users of an IPsec VPN. In this case, the IPsec VPN phase 1 configuration uses the **Accept peer ID in dialup group** peer option. The user's VPN client is configured with the username as peer ID and the password as pre-shared key. The user can connect successfully to the IPsec VPN only if the username is a member of the allowed user group and the password matches the one stored on the FortiGate unit.

A user group cannot be used as a dialup group if any member of the group is authenticated using an external authentication server.

For more information, see the [FortiOS Handbook IPsec VPN](#) guide.

Configuring a firewall user group

A user group can contain:

- local users, whether authenticated by the FortiGate unit or an authentication server
- PKI users
- authentication servers, optionally specifying particular user groups on the server

To create a Firewall user group - web-based manager:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a name for the user group.
3. In **Type**, select **Firewall**.
4. Add user names to the **Members** list.
5. Add authentication servers to the **Remote groups** list.

By default all user accounts on the authentication server are members of this FortiGate user group. To include only specific user groups from the authentication server, deselect **Any** and enter the group name in the appropriate format for the type of server. For example, an LDAP server requires LDAP format, such as: `cn=users,dn=office,dn=example,dn=com`

Remote servers must already be configured in **User & Device**.

6. Select **OK**.

To create a firewall user group - CLI example:

In this example, the members of `accounting_group` are `User1` and all of the members of `rad_accounting_group` on myRADIUS external RADIUS server.

```
config user group
  edit accounting_group
    set group-type firewall
    set member User1 myRADIUS
  config match
    edit 0
      set server-name myRADIUS
      set group-name rad_accounting_group
```

```
end
end
```

Matching user group names from an external authentication server might not work if the list of group memberships for the user is longer than 8000 bytes. Group names beyond this limit are ignored.

`server_name` is the name of the RADIUS, LDAP, or TACACS+ server, but it must be a member of this group first and must also be a configured remote server on the FortiGate unit.

`group_name` is the name of the group on the RADIUS, LDAP, or TACACS+ server such as “engineering” or “cn=users,dc=test,dc=com”.

Before using group matching with TACACS+, you must first enable authentication. For example if you have a configured TACACS+ server called myTACS, use the following CLI commands.

```
config user tacacs+
  edit myTACS
    set authorization enable
  next
end
```

For more information about user group CLI commands, see the [Fortinet CLI Guide](#).

Multiple group enforcement support

Previously, when a user belonged to multiple user groups, this user could only access the group services that were within one group. With multiple group enforcement, a user can access the services within the groups that the user is part of.

For example, `userA` belongs to `user_group1`, `user_group2`, `user_group3`, and `user_group4`; previously `userA` could only access services within one of those four groups, typically the group that matches the first security policy. This can be annoying if HTTP access is in `user_group1`, FTP access is in `user_group2`, and email access is in `user_group3`. Now `userA` can access services within `user_group1`, `user_group2`, `user_group3`, and `user_group4`.

This feature is available only in the CLI and is enabled by default. It applies to RADIUS, LDAP, and TACACS+ servers. The new command for this feature is `auth-multi-group` found in `config user settings` and checks all groups a user belongs to for authentication.

User group timeouts

User groups can have timeout values per group in addition to FortiGate-wide timeouts. There are essentially three different types of timeouts that are configurable for user authentication on the FortiGate unit — idle timeout, hard timeout, and session timeout. These are in addition to any external timeouts such as those associated with RADIUS servers.

If VDOMs are enabled, the global level user setting `authtimeout` is the default all VDOMs inherit. If VDOMs are not enabled, user settings `authtimeout` is the default. The default timeout value is used when the `authtimeout` keyword for a user group is set to zero.

Each type of timeout will be demonstrated using the existing user group `example_group`. Timeout units are minutes. A value of zero indicates the global timeout is used.

Membership in multiple groups

When a user belongs to multiple groups in RADIUS groups, the group auth-timeout values are ignored. Instead the global timeout value is used. The default value is 5 minutes, but it can be set from 1 to 43200 minutes (30 days).

```
config user setting
    set auth-timeout-type idle-timeout
    set auth-timeout 300
end
```

Idle timeout

The default type of timeout is idle timeout. When a user initiates a session, it starts a timer. As long as data is transferred in this session, the timer continually resets. If data flow stops, the timer is allowed to advance until it reaches its limit. At that time the user has been idle for too long, and the user is forced to re-authenticate before traffic is allowed to continue in that session.

To configure user group authentication idle timeout - CLI:

```
config user settings
    set auth-timeout-type idle-timeout
end
config user group
    edit example_group
        set authtimeout 5 //range is 0-43200 minutes (0 = use global authtimeout value)
    next
end
```

Hard timeout

Where the idle timeout is reset with traffic, the hard timeout is absolute. From the time the first session a user establishes starts, the hard timeout counter starts. When the timeout is reached, all the sessions for that user must be re-authenticated. This timeout is not affected by any event.

To configure user group authentication hard timeout - CLI:

```
config user settings
    set auth-timeout-type hard-timeout
end
config user group
    edit example_group
        set authtimeout 43200 //range is 0-43200 minutes (0 = use global authtimeout value)
    next
end
```

Session timeout

The session timeout works much like the hard timeout in that its an absolute timer that can not be affected by events. However, when the timeout is reached existing sessions may continue but new sessions are not allowed until re-authentication takes place.

To configure a user group authentication new session hard timeout - CLI:

```
config user setting
    set auth-timeout-type new-session
end

config user group
    edit example_group
        set authtimeout 30 //range is 0-43200 minutes (0 = use global authtimeout value)
    next
end
```

SSO user groups

SSO user groups are part of FSSO authentication and contain only Windows or Novell network users. No other user types are permitted as members. Information about the Windows or Novell user groups and the logon activities of their members is provided by the Fortinet Single Sign On (FSSO) which is installed on the network domain controllers.

You can specify FSSO user groups in security policies in the same way as you specify firewall user groups. FSSO user groups cannot have SSL VPN or dialup IPsec VPN access.

For information about configuring FSSO user groups, see [Creating FSSO user groups on page 313](#). For complete information about installing and configuring FSSO, see [Agent-based FSSO on page 276](#).

Configuring peer user groups

Peer user groups can only be configured using the CLI. Peers are digital certificate holders defined using the `config user peer` command. The peer groups you define here are used in dialup IPsec VPN configurations that accept RSA certificate authentication from members of a peer certificate group.

To create a peer group - CLI

```
config user peergrp
    edit vpn_peergrp1
        set member pki_user1 pki_user2 pki_user3
    end
```

Viewing, editing, and deleting user groups

To view the list of FortiGate user groups, go to **User & Device > User Groups**.

Editing a user group

When editing a user group in the CLI you must set the type of group this will be — either a firewall group, a Fortinet Single Sign-On Service group (FSSO), a Radius based Single Sign-On Service group (RSSO), or a guest group. Once the type of group is set, and members are added you cannot change the group type without removing the members.

In the web-based manager, if you change the type of the group any members will be removed automatically.

To edit a user group - web-based manager

1. Go to **User & Device > User Groups**.
2. Select the user group that you want to edit.
3. Select the **Edit** button.
4. Modify the user group as needed.
5. Select **OK**.

To edit a user group - CLI

This example adds user3 to Group1. Note that you must re-specify the full list of users:

```
config user group
  edit Group1
    set group-type firewall
    set member user2 user4 user3
  end
```

Deleting a user group

Before you delete a user group, you must ensure there are no objects referring to, it such as security policies. If there are, you must remove those references before you are able to delete the user group.

To remove a user group - web-based manager

1. Go to **User & Device > User Groups**.
2. Select the user group that you want to remove.
3. Select the **Delete** button.
4. Select **OK**.

To remove a user group - CLI

```
config user group
  delete Group2
end
```

SSL renegotiation in firewall authentication

The `auth-ssl-allow-renegotiation` option is available under `config user setting` to allow/forbid SSL renegotiation in firewall authentication. The default value is `disable`, where a session would be terminated by `authd` once renegotiation is detected and this login would be recorded as a failure. Other behavior follows regular authentication settings.

To enable SSL renegotiation - CLI

```
config user setting
  set auth-ssl-allow-renegotiation enable
end
```

Managing guest access

Visitors to your premises might need user accounts on your network for the duration of their stay. If you are hosting a large event such as a conference, you might need to create many such temporary accounts. The FortiOS Guest Management feature is designed for this purpose.

A guest user account User ID can be the user's email address, a randomly generated string, or an ID that the administrator assigns. Similarly, the password can be administrator-assigned or randomly generated.

You can create many guest accounts at once using randomly-generated User IDs and passwords. This reduces administrator workload for large events.

User's view of guest access

1. The user receives an email, SMS message, or printout from a FortiOS administrator listing a User ID and password.
2. The user logs onto the network with the provided credentials.
3. After the expiry time, the credentials are no longer valid.

Administrator's view of guest access

1. Create one or more guest user groups.
All members of the group have the same characteristics: type of User ID, type of password, information fields used, type and time of expiry.
2. Create guest accounts using Guest Management.
3. Use captive portal authentication and select the appropriate guest group.

Configuring guest user access

To set up guest user access, you need to create at least one guest user group and add guest user accounts. Optionally, you can create a guest management administrator whose only function is the creation of guest accounts in specific guest user groups. Otherwise, any administrator can do guest management.

Creating guest management administrators

To create a guest management administrator

1. Go to **System > Administrators** and create a regular administrator account.
For detailed information see the [System Administration](#) chapter.
2. Select **Restrict to Provision Guest Accounts**.
3. In **Guest Groups**, add the guest groups that this administrator manages.

Creating guest user groups

The guest group configuration determines the fields that are provided when you create a guest user account.

To create a guest user group:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information:

Name	Enter a name for the group.
Type	Guest
Enable Batch Account Creation	<p>Create multiple accounts automatically. When this is enabled:</p> <ul style="list-style-type: none"> • User ID and Password are set to Auto-Generate. • The user accounts have only User ID, Password, and Expiration fields. Only the Expiration field is editable. If the expiry time is a duration, such as “8 hours”, this is the time after first login. • You can print the account information. Users do not receive email or SMS notification. <p>See To create multiple guest user accounts automatically on page 204.</p>
User ID	<p>Select one of:</p> <ul style="list-style-type: none"> • Email — User’s email address • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random user ID
Password	<p>Select one of:</p> <ul style="list-style-type: none"> • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random password • Disable — no password
Expire Type	<p>Choose one of:</p> <ul style="list-style-type: none"> • Immediately — expiry time is counted from creation of account • After first login — expiry time is counted from user’s first login
Default Expire Time	Set the expire time. The administrator can change this for individual users.
Enable Name	If enabled, user must provide a name.
Enable Sponsor	If enabled, user form has Sponsor field. Select Required if required.
Enable Company	If enabled, user form has Company field. Select Required if required.
Enable Email	If enabled, user is notified by email.
Enable SMS	If enabled, user is notified by SMS. Select whether FortiGuard Messaging Service or a another SMS provider is used.

Creating guest user accounts

Guest user accounts are not the same as local user accounts created in **User & Device > User Definition**. Guest accounts are not permanent; they expire after a defined time period. You create guest accounts in **User & Device > Guest Management**.

To create a guest user account

1. Go to **User & Device > Guest Management**.
2. In **Guest Groups**, select the guest group to manage.
3. Select **Create New** and fill in the fields in the **New User** form.

Fields marked Optional can be left blank. The guest group configuration determines the fields that are available.

4. Select **OK**.

To create multiple guest user accounts automatically

1. Go to **User & Device > Guest Management**.
2. In **Guest Groups**, select the guest group to manage.
The guest group must have the **Enable Batch Guest Account Creation** option enabled.
3. Select **Create New > Multiple Users**.
Use the down-pointing caret to the right of **Create New**.
4. Enter **Number of Accounts**.
5. Optionally, change the **Expiration**.
6. Select **OK**.

Guest management account List

Go to **User & Device > Guest Management** to create, view, edit or delete guest user accounts.

Create New	Creates a new guest user account.
Edit	Edit the selected guest user account.
Delete	Delete the selected guest user account.
Purge	Remove all expired accounts from the list.
Send	Send the user account information to a printer or to the guest. Depending on the group settings and user information, the information can be sent to the user by email or SMS.
Refresh	Update the list.
Guest Groups	Select the guest group to list. New accounts are added to this group.
User ID	The user ID. Depending on the guest group settings, this can be the user's email address, an ID that the administrator specified, or a randomly-generated ID.
Expires	Indicates a duration such as "3 hours". A duration on its own is relative to the present time. Or, the duration is listed as "after first login."

Guest access in a retail environment

Some retail businesses such as coffee shops provide free WiFi Internet access for their customers. For this type of application, the FortiOS guest management feature is not required; the WiFi access point is open and customers do not need logon credentials. However, the business might want to contact its customers later with promotional offers to encourage further patronage. Using an Email Collection portal, it is possible to collect customer email addresses for this purpose. The security policy grants network access only to users who provide a valid email address.

The first time a customer's device attempts to use the WiFi connection, FortiOS requests an email address, which it validates. The customer's subsequent connections go directly to the Internet without interruption.

Creating an email harvesting portal

The customer's first contact with your network will be with a captive portal which presents a web page requesting an email address. When FortiOS has validated the email address, the customer's device MAC address is added to the Collected Emails device group.

To create the email collection portal:

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID.
2. Set **Security Mode** to **Captive Portal**.
3. Set **Portal Type** to **Email Collection**.
4. Optionally, in **Customize Portal Messages** select **Email Collection**.

You can change the portal content and appearance. See [Customizing captive portal pages on page 235](#).

To create the email collection portal - CLI:

In this example the `freewifi` WiFi interface is modified to present an email collection captive portal.

```
config wireless-controller vap
  edit freewifi
    set security captive-portal
    set portal-type email-collect
  end
```

Creating the security policy

You need configure a security policy that allows traffic to flow from the WiFi SSID to the Internet interface but only for members of the Collected Emails device group. This policy must be listed first. Unknown devices are not members of the Collected Emails device group, so they do not match the policy.

To create the security policy:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information:

Incoming Interface	freewifi
Source Address	all
Source Device Type	Collected Emails
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL

Action	ACCEPT
NAT	On

3. Select **OK**.

To create the authentication rule - CLI:

```
config firewall policy
edit 3
    set srcintf "freewifi"
    set dstintf "wan1"
    set srcaddr "all"
    set action accept
    set devices collected-emails
    set nat enable
    set schedule "always"
    set service "ALL"
end
```

Checking for harvested emails

In the web-based manager, go to **User & Device > Device Inventory**. In the CLI you can use the `diagnose user device list` command. For example,

```
FGT-100D # diagnose user device list
hosts
vd 0 d8:d1:cb:ab:61:0f gen 35 req 30 redir 1 last 43634s 7-11_2-int
ip 10.0.2.101 ip6 fe80::dad1:cbff:feab:610f
type 2 'iPhone' src http c 1 gen 29
os 'iPhone' version 'iOS 6.0.1' src http id 358 c 1
email 'yo@yourdomain.com'
vd 0 74:e1:b6:dd:69:f9 gen 36 req 20 redir 0 last 39369s 7-11_2-int
ip 10.0.2.100 ip6 fe80::76e1:b6ff:fedd:69f9
type 1 'iPad' src http c 1 gen 5
os 'iPad' version 'iOS 6.0' src http id 293 c 1
host 'Joes's-iPad' src dhcp
email 'you@fortinet.com'
```

Fall-through authentication policies

User authentication policies have an implicit fall-through feature that intentionally causes policy matching to fall through to a policy lower on the list that can also match the traffic. In other words the first user policy that is matched in the policy list, based on standard policy criteria, isn't the only policy that can be matched.

Fall-through is intended to match users in different user groups with different policies. For example, consider an organization with two user groups where one group requires a web filtering profile, while the other requires virus scanning. In this example, you would edit two basic Internet access policies: policy 1 assigning **User Group A** with a **Web Filtering** profile, and policy 2 assigning **User Group B** with an **AntiVirus** profile. Both policies are also assigned to the same internal subnet, named **subnet1**.

In this configuration, all users from **subnet1** will see an authentication prompt. If the user is found in **User Group A**, the traffic is accepted by policy 1 and is filtered by the **Web Filtering** profile. If the user is found in **User Group B**, the traffic is accepted by policy 2 and is virus scanned.

The fall-through feature is required for users to be matched with policy 2. Without the fall-through feature, traffic would never be matched with policy 2.

Configuring authenticated access

When you have configured authentication servers, users, and user groups, you are ready to configure security policies and certain types of VPNs to require user authentication.

This section describes:

- [Authentication timeout](#)
- [Password policy](#)
- [Authentication protocols](#)
- [Authentication in captive portals](#)
- [Authentication in security policies](#)
- [Authentication replacement messages](#)
- [VPN authentication](#)

Authentication timeout

An important feature of the security provided by authentication is that it is temporary—a user must re-authenticate after logging out. Also if a user is logged on and authenticated for an extended period of time, it is a good policy to have them re-authenticate at set periods. This ensures a user's session is cannot be spoofed and used maliciously for extended periods of time — re-authentication will cut any spoof attempts short. Shorter timeout values are more secure.

Security authentication timeout

You set the security user authentication timeout to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 4320 minutes (72 hours).

To set the security authentication timeout - web-based manager:

1. Go to **User & Device > Authentication Settings**.
2. Enter the **Authentication Timeout** value in minutes.
The default authentication timeout is 5 minutes.
3. Select **Apply**.

SSL VPN authentication timeout

You set the SSL VPN user authentication timeout (**Idle Timeout**) to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 259 200 seconds. The default timeout is 300 seconds.

To set the SSL VPN authentication timeout - web-based manager:

1. Go to **VPN > SSL-VPN Settings**.
2. Enable **Idle Logout** and enter the **Inactive For** value in seconds.
3. Select **Apply**.

Password policy

Password authentication is effective only if the password is sufficiently strong and is changed periodically. By default, the FortiGate unit requires only that passwords be at least eight characters in length, but up to 128 characters is permitted. You can set a password policy to enforce higher standards for both length and complexity of passwords. Password policies can apply to administrator passwords or IPsec VPN pre-shared keys.

To set a password policy in the web-based manager, go to **System > Settings**. In the CLI, use the `config system password-policy` command.

Users usually create passwords composed of alphabetic characters and perhaps some numbers. Password policy can require the inclusion of uppercase letters, lowercase letters, numerals or punctuation characters.

Configuring password minimum requirement policy

Best practices dictate that passwords include:

- one or more uppercase characters
- one or more lower case characters
- one or more of the numerals
- one or more special characters.

The minimum number of each of these types of characters can be set in both the web-based manager and the CLI.

The following procedures show how to force administrator passwords to contain at least two uppercase, four lower case, two digits, and one special character. Leave the minimum length at the default of eight characters.

To change administrator password minimum requirements - web-based manager:

1. Go to **System > Settings**.
2. Select **Enable Password Policy**.
3. Select **Must Contain at Least**.
4. Enter the following information:

Upper Case Letters	2
Lower Case Letters	4
Numbers	2
Special Characters	1

5. Under **Apply Password Policy to**, select **Administrator Password**.
6. Select **Apply**.

To change administrator password minimum requirements - CLI:

```
config system password-policy
  set status enable
  set apply-to admin-password
  set min-upper-case-letter 2
  set min-lower-case-letter 4
```

```
set min-number 2
set min-non-alphanumeric 1
set change-4-characters enable
end
```

The `change-4-characters` option forces new passwords to change a minimum of four characters in the old password. Changing fewer characters results in the new password being rejected. This option is only available in the CLI.

To configure a guest administrator password policy - CLI:

As of FortiOS 5.4, a password policy can also be created for guest administrators. The following command shows all possible commands, which are also available under `config system password-policy`.

```
config system password-policy
  set status {enable | disable} Enable/disable password policy.
  set apply-to {guest-admin-password} Guest admin to which this password policy applies.
  set minimum-length <8-128> Minimum password length.
  set min-lower-case-letter <0-128> Min. lowercase characters in password.
  set min-upper-case-letter <0-128> Min. uppercase characters in password.
  set min-non-alphanumeric <0-128> Min. non-alphanumeric characters in password.
  set min-number <0-128> Min. numeric characters in password.
  set change-4-characters {enable | disable} Enable/disable changing at least 4 characters for new password.
  set expire-status {enable | disable} Enable/disable password expiration.
  set expire-day <1-999> Number of days before password expires.
  set reuse-password {enable | disable} Enable/disable reuse of password.
end
```

Password best practices

In addition to length and complexity, there are security factors that cannot be enforced in a policy. Guidelines issued to users will encourage proper password habits.

Best practices dictate that password expiration also be enabled. This forces passwords to be changed on a regular basis. You can set the interval in days. The more sensitive the information this account has access to, the shorter the password expiration interval should be. For example 180 days for guest accounts, 90 days for users, and 60 days for administrators.

Avoid:

- real words found in any language dictionary
- numeric sequences, such as “12345”
- sequences of adjacent keyboard characters, such as “qwerty”
- adding numbers on the end of a word, such as “hello39”
- adding characters to the end of the old password, such as “hello39” to “hello3900”
- repeated characters
- personal information, such as your name, birthday, or telephone number.

In the case where the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

Maximum login attempts and blackout period

When you login and fail to enter the correct password you could be a valid user, or a hacker attempting to gain access. For this reason, best practices dictate to limit the number of failed attempts to login before a blackout period where you cannot login.

To set a maximum of five failed authentication attempts before the blackout, using the following CLI command:

```
config user setting
    set auth-invalid-max 5
end
```

To set the length of the blackout period to five minutes, or 300 seconds, once the maximum number of failed login attempts has been reached, use the following CLI command:

```
config user setting
    set auth-blackout-time 300
end
```

Authentication protocols

When user authentication is enabled on a security policy, the authentication challenge is normally issued for any of the four protocols, HTTP, HTTPS, FTP, and Telnet, which are dependent on the connection protocol. By making selections in the Protocol Support list, the user controls which protocols support the authentication challenge. The user must connect with a supported protocol first, so that they can subsequently connect with other protocols.

For example, if you have selected HTTP, FTP, or Telnet, a username and password-based authentication occurs. The FortiGate unit then prompts network users to input their security username and password. If you have selected HTTPS, certificate-based authentication (HTTPS, or HTTP redirected to HTTPS only) occurs.

FTP and Telnet authentication replacement messages cannot be customized. For HTTP and HTTPS replacement messages see [Authentication replacement messages on page 213](#).

For certificate-based authentication, you must install customized certificates on the FortiGate unit and on the browsers of network users. If you do not install certificates on the network user's web browser, the network users may see an SSL certificate warning message and have to manually accept the default FortiGate certificate. The network user's web browser may deem the default certificate as invalid.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings are used. If you specify a certificate, the per-policy setting will overwrite the global setting. For more information about the use of certification authentication see [Certificate-based authentication on page 241](#).

To set the authentication protocols

1. Go to **User & Device > Authentication Settings**.
2. In **Protocol Support**, select the required authentication protocols.
3. If using HTTPS protocol support, in **Certificate**, select a Local certificate from the drop-down list.
4. Select **Apply**.

Authentication in captive portals

Network interfaces, including WiFi interfaces, can perform authentication at the interface level using a captive portal — an HTML form that requests the user's name and password. A captive portal is useful where all users connecting to the network interface must authenticate. Optionally, on a WiFi interface, the captive portal can be combined with a terms of service disclaimer to which the user must agree before gaining access. For more information, see [Captive portals on page 233](#).

Once successfully authenticated, the user's session passes to the firewall.

Authentication in security policies

Security policies control traffic between FortiGate interfaces, both physical interfaces and VLAN subinterfaces. The firewall tries to match the session's user or group identity, device type, destination, or other attribute to a security policy. When a match is found, the user connects to the requested destination. If no security policy matches, the user is denied access.

A user who has not already been authenticated by a captive portal, FSSO, or RSSO can match only policies where no user or user group is specified. If no such policy exists, the firewall requests authentication. If the user can authenticate and the session can be matched to a policy, the user connects to the requested destination, otherwise, the user is denied access.

This section includes:

- [Enabling authentication protocols](#)
- [Authentication replacement messages](#)
- [Access to the Internet](#)
- [Configuring authentication security policies](#)
- [Identity-based policy](#)
- [NTLM authentication](#)
- [Certificate authentication](#)
- [Restricting number of concurrent user logins](#)

Enabling authentication protocols

Users can authenticate using FTP, HTTP, HTTPS, and Telnet. However, these protocols must be enabled first.

Another authentication option is to redirect any attempts to authenticate using HTTP to a more secure channel that uses HTTPS. This forces users to a more secure connection before entering their user credentials.

To enable support for authentication protocols - web-based manager:

1. Go to **User & Device > Authentication Settings**.
2. Select one or more of HTTP, HTTPS, FTP, Telnet, or Redirect HTTP Challenge to a Secure Channel (HTTPS). Only selected protocols will be available for use in authentication.
3. Select the **Certificate** to use, for example `Fortinet_Factory`.
4. Select **Apply**.

To enable support for authentication protocols - CLI:

```
config user setting
```

```

set auth-type ftp http https telnet
set auth-cert Fortinet_Factory
end

```

As of FortiOS 5.4, the `Fortinet_Factory` certificate has been re-signed with an expiration date of 2038. It is used instead of `Fortinet_Factory2`, which has been removed.

Authentication replacement messages

A replacement message is the body of a web page containing a message about a blocked website message, a file too large message, a disclaimer, or even a login page for authenticating. The user is presented with this message instead of the blocked content.

Authentication replacement messages are the prompts a user sees during the security authentication process such as login page, disclaimer page, and login success or failure pages. These are different from most replacement messages because they are interactive requiring a user to enter information, instead of simply informing the user of some event as other replacement messages do.

Replacement messages have a system-wide default configuration, a per-VDOM configuration, and disclaimers can be customized for multiple security policies within a VDOM.

These replacement messages are used for authentication using HTTP and HTTPS. Authentication replacement messages are HTML messages. You cannot customize the security authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

More information about replacement messages can be found in the `config system replacemsg` section of the [FortiOS CLI Reference](#).

List of authentication replacement messages

Replacement message name (CLI name)	Description
Login challenge page (auth-challenge-page)	<p>This HTML page is displayed if security users are required to answer a question to complete authentication. The page displays the question and includes a field in which to type the answer. This feature is supported by RADIUS and uses the generic RADIUS challenge-access auth response. Usually, challenge-access responses contain a Reply-Message attribute that contains a message for the user (for example, "Please enter new PIN"). This message is displayed on the login challenge page. The user enters a response that is sent back to the RADIUS server to be verified.</p> <p>The Login challenge page is most often used with RSA RADIUS server for RSA SecurID authentication. The login challenge appears when the server needs the user to enter a new PIN. You can customize the replacement message to ask the user for a SecurID PIN.</p> <p>This page uses the <code>%%QUESTION%%</code> tag.</p>

Replacement message name (CLI name)	Description
Disclaimer page (auth-disclaimer-page-1) (auth-disclaimer-page-2) (auth-disclaimer-page-3)	<p>This page prompts user to accept the displayed disclaimer when leaving the captive portal to access Internet resources. It is displayed when the captive portal type is Authentication and Disclaimer or Disclaimer Only.</p> <p>In the CLI, the auth-disclaimer-page-2 and auth-disclaimer-page-3 pages seamlessly extend the size of the disclaimer page from 8 192 characters to 16 384 and 24 576 characters respectively. In the web-based manager this is handled automatically.</p> <p>See Disclaimer on page 216.</p>
Email token page (auth-email-token-page)	<p>The page prompting a user to enter their email token. See Email on page 1.</p>
FortiToken page (auth-fortitoken-page)	<p>The page prompting a user to enter their FortiToken code. See FortiToken on page 188.</p>
Keepalive page (auth-keepalive-page)	<p>The HTML page displayed with security authentication keepalive is enabled using the following CLI command:</p> <pre>config system globalset auth-keepalive enable end</pre> <p>Authentication keepalive keeps authenticated firewall sessions from ending when the authentication timeout ends. In the web-based manager, go to User & Device > Authentication Settings to set the Authentication Timeout.</p> <p>This page includes %%TIMEOUT%%.</p>
Login failed page (auth-login-failed-page)	<p>The Disclaimer page replacement message does not re-direct the user to a redirect URL or the security policy does not include a redirect URL. When a user selects the button on the disclaimer page to decline access through the FortiGate unit, the Declined disclaimer page is displayed.</p>
Login page (auth-login-page)	<p>The authentication HTML page displayed when users who are required to authenticate connect through the FortiGate unit using HTTP or HTTPS.</p> <p>Prompts the user for their username and password to login.</p> <p>This page includes %%USERNAMEID%% and %%PASSWORDID%% tags.</p>
Declined disclaimer page (auth-reject-page)	<p>The page displayed if a user declines the disclaimer page. See Disclaimer on page 216.</p>

Replacement message name (CLI name)	Description
SMS Token page (auth-sms-token-page)	The page prompting a user to enter their SMS token. See SMS on page 187 .
Success message (auth-success-msg)	The page displayed when a user successfully authenticates. Prompts user to attempt their connection again (as the first was interrupted for authentication).

Access to the Internet

A policy for accessing the Internet is similar to a policy for accessing a specific network, but the destination address is set to **all**. The destination interface is the one that connects to the Internet Service Provider (ISP). For general purpose Internet access, the Service is set to ALL.

Access to HTTP, HTTPS, FTP and Telnet sites may require access to a domain name service. DNS requests do not trigger authentication. You must configure a policy to permit unauthenticated access to the appropriate DNS server, and this policy must **precede** the policy for Internet access. Failure to do this will result in the lack of a DNS connection and a corresponding lack of access to the Internet.

Configuring authentication security policies

To include authentication in a security policy, the policy must specify user groups. A security policy can authenticate by certificate, FSSO, and NTLM. The two exceptions to this are RADIUS SSO and FSSO Agents. See [SSO using RADIUS accounting records on page 321](#), and [Introduction to FSSO agents on page 277](#).

Before creating a security policy, you need to configure one or more users or user groups. For more information, see [Users and user groups on page 181](#).

Creating the security policy is the same as a regular security policy except you must select the action specific to your authentication method:

Authentication methods allowed for each policy Action

Action	Authentication method	Where authentication is used
ACCEPT	FSSO Agent or a security policy that specifies an FSSO user group	Agent-based FSSO on page 276 .
	NTLM	See NTLM authentication on page 217 .
	Certificates	See Configuring certificate-based authentication on page 255 .
	RADIUS SSO	See SSO using RADIUS accounting records on page 321 .
DENY	none	none

Disclaimer

A WiFi or SSL captive portal can include a disclaimer message presented after the user authenticates. The user must agree to the terms of the disclaimer to access network resources.

Customizing authentication replacement messages

Customizing disclaimers or other authentication replacement messages involves changing the text of the disclaimer message, and possibly the overall appearance of the message.

Changing the disclaimer in **System > Replacement Messages** is not the same as selecting to customize a disclaimer used in a captive portal. The captive portal location is a customized disclaimer that inherits the default format for the disclaimer message, but then can be customized for this portal.

To customize the disclaimer for a captive portal - web-based manager:

1. Go to **Network > Interfaces**. Either select an existing interface or create a new one.
2. Under **Security Mode**, select **Captive Portal**, and enable **Customize Portal Messages**.
3. Select the **Edit** icon. You can select and edit any of the pages. Change your text or layout as needed.

Enabling security logging

There are two types of logging that relate to authentication — event logging, and security logging.

When enabled, event logging records system events such as configuration changes, and authentication. To configure event logging, go to **Log & Report > Log Settings** and enable **Event Logging**. Select the events you want to log, such as **User activity event**.

When enabled, security logging will log security profile and security policy traffic.

You must enable logging within a security policy, as well as the options that are applied to a security policy, such as security profiles features. Event logs are enabled within the Event Log page.

For more information on logging, see the FortiOS Log and Reporting guide.

For more information on specific types of log messages, see the FortiOS Log Message Reference.

You need to set the logging severity level to **Notification** when configuring a logging location to record traffic log messages.

To enable logging within an existing security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Expand to reveal the policy list of a policy.
3. Select the security policy you want to enable logging on and then select **Edit**.
4. To log all general firewall traffic, select the check box beside **Log Allowed Traffic**, and choose to enable **Security Events** or **All Sessions**.
5. Select **OK**.

Identity-based policy

An identity-based policy (IBP) performs user authentication in addition to the normal security policy duties. If the user does not authenticate, access to network resources is refused. This enforces Role Based Access Control (RBAC) to your organization's network and resources.

Identity-based policies also support Single Sign-On operation. The user groups selected in the policy are of the Fortinet Single Sign-On (FSSO) type.

User authentication can occur through any of the following supported protocols, including: HTTP, HTTPS, FTP, and Telnet. The authentication style depends on which of these protocols is included in the selected security services group and which of those enabled protocols the network user applies to trigger the authentication challenge.

For username and password-based authentication (HTTP, FTP, and Telnet) the FortiGate unit prompts network users to enter their username, password, and token code if two-factor authentication is selected for that user account. For certificate-based authentication, including HTTPS or HTTP redirected to HTTPS only, see [Certificate authentication on page 228](#).

With identity-based policies, the FortiGate unit allows traffic that matches the source and destination addresses, device types, and so on. This means specific security policies must be placed **before** more general ones to be effective.

When the identity-based policy has been configured, the option to customize authentication messages is available. This allows you to change the text, style, layout, and graphics of the replacement messages associated with this firewall policy. When enabled, customizing these messages follows the same method as changing the disclaimer. See [Disclaimer on page 216](#).

Types of authentication also available in identity-based policies are

- [NTLM authentication](#)
- [Certificate authentication](#)

NTLM authentication

NT LAN Manager (NTLM) protocol can be used as a fallback for authentication when the Active Directory (AD) domain controller is unreachable. NTLM uses the web browser to send and receive authentication information. See "NTLM" and "FSSO NTLM authentication support".

To enable NTLM

1. Edit the policy in the CLI to enable NTLM. For example, if the policy ID is 4:
2. Go to **Policy & Objects > IPv4 Policy** and note the **ID** number of your FSSO policy.
3. The policy must have an FSSO user group as **Source User(s)**. There must be at least one FSSO Collector agent configured on the FortiGate unit.

```
config firewall policy
edit 4
set ntlm enable
end
```

NTLM guest access

Guest profile access may be granted to users who fail NTLM authentication, such as visitors who have no user credentials on the network. To allow guest user access, edit the FSSO security policy in the CLI, like this:

```
config firewall policy
  edit 4
    set ntlm enable
    set ntlm-guest enable
  end
```

NTLM enabled browsers - CLI

User agent strings for NTLM enabled browsers allow the inspection of initial HTTP-User-Agent values, so that non-supported browsers are able to go straight to guest access without needlessly prompting the user for credentials that will fail. `ntlm-guest` must be enabled to use this option.

```
config firewall policy
  edit 4
    set ntlm enable
    set ntlm-guest enable
    set ntlm-enabled-browsers <user_agent_string>
  next
end
```

`<user_agent_string>` is the name of the browser that is NTLM enabled. Examples of these values include "MSIE", "Mozilla" (which includes FireFox), and "Opera".

Value strings can be up to 63 characters in length, and may not contain cross site scripting (XSS) vulnerability characters such as brackets. The FortiGate unit prevents use of these characters to prevent exploit of cross site scripting (XSS) vulnerabilities.

Kerberos authentication for explicit web and transparent web proxy users

Kerberos authentication is a method for authenticating both explicit web proxy and transparent web proxy users. It has several advantages over NTLM challenge response:

- Does not require FSSO/AD agents to be deployed across domains.
- Requires fewer round-trips than NTLM SSO, making it less latency sensitive.
- Is (probably) more scalable than challenge response.
- Uses existing Windows domain components rather than added components.
- NTLM may still be used as a fallback for non-Kerberos clients.

Enhancements to Kerberos explicit and transparent web proxy

FortiOS 5.6.x authentication is managed by schemes and rules based on protocol and source address. As such, configurable authentication settings have been introduced to enhance authentication.

CLI commands (`config authentication rule, scheme, and setting`) allow explicit proxy rules and schemes to be created to separate user authentication (e.g. authentication rules and schemes used to match conditions in order to identify users) from user authorization (proxy-based policies with users and/or user groups).

CLI syntax - config authentication rule

```

config authentication rule
  edit <name>
    set name <name>
    set status {enable|disable}
    set protocol {http|ftp|socks}
    config srcaddr <addr-name or addrgrp-name>
      edit <name>
        set name <ipv4-policy-name>
      next
    end
    config srcaddr6 <addr-name or addrgrp-name>
      edit <name>
        set name <ipv6-policy-name>
      next
    end
    set ip-based {enable|disable}
    set active-auth-method <scheme-name>
    set sso-auth-method <scheme-name>
    set transaction-based {enable|disable} - basic scheme + session-based
    set web-auth-cookie {enable|disable}
    set comments <comments>
  next
end

```

Note: As shown above, HTTP, FTP, and SOCKSv5 authentication protocols are supported for explicit proxy.

Authentication rules are used to receive user-identity, based on the values set for protocol and source address. Having said this, if a rule fails to match based on source address, there will be no other attempt to match the rule, however the next policy will be attempted. This occurs only when:

- there is an authentication rule, but no authentication method has been set (under `config authentication scheme`; see below), so user identity cannot be found.
- the user is successfully matched in the rule, but fails to match the current policy.

Once a rule is positively matched through protocol and/or source address, it must also match the authentication method specified (`active-auth-method` and `sso-auth-method`). These methods point to schemes, as defined under `config authentication scheme`.

CLI syntax - config authentication scheme

```

config authentication scheme
  edit <name>
    set name <name>
    set method {basic|digest|ntlm|form|negotiate|fsso|rsso}
    set negotiate-ntlm {enable|disable}
    set require-tfa {enable|disable}
    set fsso-guest {enable|disable}
    config user-database
      edit <name>
        set name {local|<ldap-server>|<radius-server>|<fsso-name>|<rsso-name>|<tacacs+-name>}
      next
    end
  next
end

```

```
end
```

Combining authentication rules and schemes, granular control can be exerted over users and IPs, creating an efficient process for users to successfully match a criteria before matching the policy.

Additional options can be set under `config authentication setting`.

CLI syntax - config authentication setting

```
config authentication setting
  set sso-scheme <scheme-name>
  set active-scheme <scheme-name>
  set captive-portal <host-name>
  set captive-portal-port <tcp-port>
end
```

Integration of transparent and explicit proxy HTTP policy checking

A CLI command, under `config firewall profile-protocol-options`, allows HTTP policy checking to be enable or disabled. When enabled, transparent traffic can be matched in a firewall policy and policy user authentication can occur. In addition, separate SSL inspection policies can be created:

```
config firewall profile-protocol-options
  edit <name>
    set http-policy {enable|disable}
  end
```

Internet Service Database in Explicit/Implicit proxy policies

CLI commands, under `config firewall proxy-policy`, implement the Internet Service Database (ISDB) as the webproxy matching factor, and override IP pool is also support:

```
config firewall proxy-policy
  edit <name>
    set proxy {explicit-web|transparent-web|ftp|wanopt}
    set dstintf <dst-name>
    set poolname <ip-pool-name>
  end
```

Multiple port/port range support for explicit web and explicit FTP proxy

Multiple port numbers and/or ranges can be set for explicit proxy, specifically for HTTP/HTTPS and FTP. Go to **Network > Explicit Proxy** and configure settings under **Explicit Web Proxy** and **Explicit FTP Proxy**, or under `config web-proxy explicit` in the CLI Console.

1. General configuration

1.1 Kerberos environment - Windows server setup

1. Build a Windows 2008 Platform server.
2. Enable domain configuration in windows server (dcpromo).
3. Set the domain name TEST.COM (realm name).

1.2 Create users

- *testuser* is a normal user (could be any existing domain user account).
- *testfgt* is the service name. In this case it should be the FQDN for the explicit proxy Interface, For example the hostname in the client browser proxy config.
- Recommendation: create username all in lowercase (even if against corporate standards).
 - The account only requires “domain users” membership
 - Password set to never expire
 - Set a very strong password

1.3 Add FortiGate to DNS

Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa

For Lab/Testing add the FortiGate Domain name and IP mapping in the hosts file (windows/system32/drivers/etc/hosts). e.g., `TESTFGT.TEST.COM 10.10.1.10`

1.4 Generate the Kerberos keytab

Use the *ktpass* command (found on Windows Servers and many domain workstations) to generate the Kerberos keytab.

Example:

```
ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser testfgt -pass <password> -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

In the case where the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

The ktpass on older Windows servers (i.e. 2003) may not support the “all” crypto option.

Example:

```
ktpass -princ HTTP/testfgt.test.com@TEST.COM -mapuser testfgt -pass 12345678 -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

The realm name is always presented in uppercase, and prefixed with the “@” character.

1.5 Encode base64

Use the `base64` command (available in most Linux distros) command to encode the `fgt.keytab` file. Any LF (Line Feed) need to be deleted from the file.

Example:

```
base64 fgt.keytab > fgt.txt
```

Use Notepad++ or some native Linux text editor. Windows Notepad and Wordpad are likely to introduce errors.

2. FortiGate configuration

2.1 Create LDAP server instance

```
config user ldap
  edit "ldap" <<< Required for authorization
    set server "10.10.1.1" <<< LDAP server IP, normally it should be same as KDC server
    set cnid "cn"
    set dn "dc=test,dc=com"
    set type regular
    set username "CN=admin,CN=Users,DC=test,DC=com" <<< Your domain may require STARTTLS
    set password <FOOS>
  next
end
```

2.2 Define Kerberos as an authentication service

```
config user krb-keytab
  edit "http_service"
    set principal "HTTP/testfgt.test.com@TEST.COM" <<< Same as the principal name in 1.4
    set ldap-server "ldap" <<< the defined ldap server for authorization
    set keytab
      "BQIAAABNAAIACKJFUkJFUj5DT00ABEhUVFAAGlRPT1lfRkdUXzEwMERfQS5CRVJCVRViuQ09NAAAAQA
      AAAAKABcAEJQl0MHgovwplu7XzfENJzw=" <<< base64 encoding keytab data, created in step 1.5
    next
  end
```

2.3 Create user group(s)

```
config user group <<< the group is used for kerberos authentication
  edit "testgrp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap" <<< Same as ldap-server option in krb-keytab
        set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
      next
    end
  next
end
```

2.4 Create firewall policy

```
config firewall proxy-policy
edit 1
set uuid 5e5dd6c4-952c-51e5-b363-120ad77c1414
set proxy explicit-web
set dstintf "port1"
set srcaddr "all"
set dstaddr "all"
set service "webproxy"
set action accept
set schedule "always"
set groups "CN=USERS LAB.PS FSSO"
next
end
```

2.5 Diagnostics

Once the keytab is imported, check that it has been properly decoded. The filename generated will be relatively random, but should be clearly visible.

```
Artoo-Deetoo (root) # fnsysctl ls -la /tmp/kt
drwxr--r-- 2 0 0 Fri Dec 2 10:06:43 2016 60 .
drwxrwxrwt 22 0 0 Tue Dec 6 14:28:29 2016 3280 ..
-rw-r--r-- 1 0 0 Fri Dec 2 10:06:43 2016 392 1.0.89.keytab
```

If there is no file present, then the file hasn't decoded. Check the file for line feeds and try again.

3. Client side walkthrough

3.1 Check Kerberos is working

Log on to the domain by using *testuser*, created in 1.2. Use the *klist* command to list ticket information. In the below example, the client has received *krbtgt*, *CIFS*, and *LDAP* tickets. As there has been no interaction with the FortiGate, there are no references to it.

```
C:\Users\glenk>klist Cached Tickets: (5)

C:\Users\glenk>klist
Cached Tickets: (5)
#0> Client: glenk @ home.local

    Server: krbtgt/HOME.LOCAL @ HOME.LOCAL
    KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
    Ticket Flags 0x60a00000 -> forwardable forwarded renewable pre_authent
    Start Time: 12/6/2016 14:58:06 (local)
    End Time: 12/7/2016 0:58:04 (local)
    Renew Time: 12/13/2016 14:58:04 (local)
    Session Key Type: AES-256-CTS-HMAC-SHA1-96

Session Key Type: AES-256-CTS-HMAC-SHA1-96

#3> Client: glenk @ home.local

Server: ldap/EthicsGradient.home.local @ HOME.LOCAL
Kerberos Ticket Encryption Type: AES-256-CTS-HMAC-SHA1-96
Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
Start Time: 12/6/2016 14:58:06 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: AES-256-CTS-HMAC-SHA1-96

#4> Client: glenk @ home.local

Server: LDAP/EthicsGradient.home.local/home.local @ HOME.LOCAL
Kerberos Ticket Encryption Type: AES-256-CTS-HMAC-SHA1-96
Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
Start Time: 12/6/2016 14:58:06 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: AES-256-CTS-HMAC-SHA1-96

```

3.2 Configure client

Set up web-proxy in browser through the FortiGate. This can be achieved via a PAC file or direct browser configuration.

Some Firefox documentation indicates that it is necessary to make manual advanced configuration changes to allow Kerberos authentication work. However, builds 48 (and possibly much earlier) require no additional configuration beyond setting of the proxy server.

3.3 Open a connection to the Internet

1. The client accesses the explicit proxy, but a *HTTP 407 Proxy Authentication Required* is returned.
2. As "Negotiate" is set, the client has knowledge of the KRB-TGT, it requests a ticket from the KDC with a *krb-tgs-req* message. This includes the REALM (HOME.LOCAL) in the *req-body* section, and the provided instances SNAME and service (in this case, HTTP/artoo-deetoo.home.local).
3. The KDC responds with a next KRB-TGS-REP.

This ticket is then available on the client.

In the example below, the ticket-granted-service has issued Ticket #2.

```
#2> Client: glenk @ home.local
```

```

Server: HTTP/artoo-deetoo.home.local @ HOME.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC (NT)
Ticket Flags 0x40a00000 -> forwardable renewable pre_authent
Start Time: 12/6/2016 14:59:45 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: RSADSI RC4-HMAC (NT)

```

4. The conversation between the client and the proxy continues, as the client responds with the Kerberos ticket in the response.

The whole process takes less than a second to complete. The user should be visible as a FSSO logon in the Web UI.

Transparent web-proxy Kerberos authentication

Transparent web-proxy allows the FortiGate to process level 7 policy matching, even when the explicit web-proxy is not enabled on the client's browser. The transparent web-proxy policy is set in proxy-policy too. The policy matching rule is the same as the explicit web-proxy.

In the firewall policy level, transparent web-proxy is regarded as a special UTM. The HTTP/HTTPS traffic matches the firewall policy first, then traffic is redirected to the web-proxy daemon. If the transparent web-proxy feature is disabled, http-policy options in profile-protocol-options is used to enable transparent web-proxy feature.

IP-based

Kerberos authentication requires the captive portal to be an FQDN address that is resolved to a local IP address. However, it becomes more complicated to setup an FQDN address in a local user deployment. Therefore you can set the `captive-portal-type` to either use an FQDN or IP address.

1. Captive portal and the captive portal port must be configured in transparent web-proxy for support of Kerberos authentication:

```

config authentication setting
    set captive-portal-type {fqdn | ip}
    set captive-portal <fqdn-name> / <ip>
    set captive-portal-port "9998"
end

```

2. Authentication rule, scheme, and krb-keytab need to be configured for Kerberos authentication (note the `active-auth-method` scheme referenced in the rule):

```

config authentication scheme
    edit <kerberos-scheme>
        set method negotiate
        set negotiate-ntlm <enable>
        set fsso-guest <disable>
    next
end

config authentication rule
    edit <name>
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <enable>

```

```

        set active-auth-method <kerberos-scheme>
    next
end

config user krb-keytab
    edit <name>
        set principal "HTTP/TESTFGT.TEST.COM@TEST.COM"
        set ldap-server "ldap"
        set keytab <base64-encoding-keytab-data>
    next
end

```

3. Configure LDAP and user group used for authorization:

```

config user ldap
    edit "ldap"
        set server "10.10.1.1"
        set cnid
        set dn
        set type <regular>
        set username "CN=admin,CN=Users,DC=test,DC=com"
        set password ENC
            aW5lIAHkPMf4D+ZCKpGMU3x8Fpq0G+7uIbAvpblbXFA5vLfGb4/oRBx+B6R/v+CMCetP84e+Gdz5zEcM
            yOd3cj0BoIhFrpYJfXhRs4lSE0HezeVXfxwTSf5VJG+F11G/G5RpaY+AE8bortC8MBe7P2/uGQocFHu4
            Ilulp5I60Jvyk6Ei3hDZMjTd8iPp5IkRJZVVjQ==
    next
end

config user group
    edit "testgrp"
        set member "ldap"
        config match
            edit "1"
                set server-name "ldap"
                set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
            next
        end
    next
end

```

4. Create proxy-policy, with groups as the authorizing policy-matching element:

```

config firewall proxy-policy
    edit 1
        set uuid 1bbb891a-9cd2-51e7-42ff-d1fa13cac3da
        set proxy explicit-web
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set groups testgrp
    next
end

```

5. UTM must be enabled in the firewall policy to support the transparent web-proxy:

```

config firewall policy

```

```

edit "1"
    set name "policy1"
    set uuid 8a6ceeac-b016-51e6-2b5c-165070d5bf50
    set srcintf "mgmt1"
    set dstintf "mgmt1"
    set srcaddr "all"
    set dstaddr "all"
    set action <accept>
    set schedule "always"
    set service "ALL"
    set utm-status <enable>
    set profile-protocol-options "transparent-web-proxy"
    set ssl-ssh-profile "deep-inspection"
    set nat <enable>
next
end

config firewall profile-protocol-options
    edit "transparent-web-proxy"
        config http
            set ports "80 8080"
            unset options
            set http-policy enable
            unset post-lang
        end
        ...
    next
end

```

Session-based with web-auth cookie

The web-auth-cookie feature is necessary for session-based authentication under transparent web-proxy.

The configuration is the same as for IP-based authentication, except `ip-based` is disabled in the authentication rule:

```

config authentication rule
    edit "kerberos-rules"
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <disable>
        set active-auth-method <kerberos-scheme>
    next

config authentication setting
    set captive-portal <fqdn-name>
    set captive-portal-port "9998"
end

```

HTTP tunnel authentication

You can trigger user authentication on HTTP CONNECT request at the policy level. A new CLI entry has been added under `config firewall proxy-policy` which will trigger the authentication process `get-user`, even when there is no user or group configured.

Note that, as shown below, explicit web proxy must be set.

Syntax

```
config firewall proxy-policy
  edit {policyid}
    set proxy explicit-web
    set http-tunnel-auth {enable | disable}
  next
end
```

Certificate authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users. See [Configuring certificate-based authentication on page 255](#).

Certificates are also inherent to the HTTPS protocol, where the browser validates the server's identity using certificates. A site certificate must be installed on the FortiGate unit and the corresponding Certificate Authority (CA) certificate installed in the web browser.

To force the use of HTTPS, go to **User & Device > Authentication Settings** and select **Redirect HTTP Challenge to a Secure Channel (HTTPS)**.

Restricting number of concurrent user logins

Some users on your network may often have multiple account sessions open at one time either to the same network resource or accessing to the admin interface on the FortiGate unit.

While there are valid reasons for having multiple concurrent sessions open, hackers also do this to speed up their malicious work. Often a hacker is making multiple attempts to gain access to the internal network or the admin interface of the FortiGate unit, usually from different IP addresses to appear to the FortiGate unit as legitimate users. For this reason, the more concurrent sessions a hacker has open at once, the faster they will achieve their goal.

To help prevent this, you can disallow concurrent administrative access using the same administrator user name. This allows only one session with the same username even if it is from the same IP.

To disable concurrent administrator sessions - CLI:

```
config system global
  set admin-concurrent disable
end
```

VPN authentication

All VPN configurations require users to authenticate. Authentication based on user groups applies to:

- SSL VPNs
- PPTP and L2TP VPNs
- an IPsec VPN that authenticates users using dialup groups
- a dialup IPsec VPN that uses XAUTH authentication (Phase 1)

You must create user accounts and user groups before performing the procedures in this section. If you create a user group for dialup IPsec clients or peers that have unique peer IDs, their user accounts must be stored locally on the FortiGate unit. You cannot authenticate these types of users using a RADIUS or LDAP server.

Configuring authentication of SSL VPN users

The general procedure for authenticating SSL VPN users is:

1. Configure user accounts.
2. Create one or more user groups for SSL VPN users.
3. Enable SSL VPN.
4. Optionally, set inactivity and authentication timeouts.
5. Configure a security policy with the user groups you created for SSL VPN users.
See FortiOS Handbook SSL VPN guide.

Configuring authentication timeout

By default, the SSL VPN authentication expires after 8 hours (28 800 seconds). You can change it only in the CLI, and the time entered must be in seconds. The maximum time is 72 hours (259 200 seconds). For example, to change this timeout to one hour, you would enter:

```
config vpn ssl settings
    set auth-timeout 3600
end
```

If you set the authentication timeout (`auth-timeout`) to 0 when you configure the timeout settings, the remote client does not have to re-authenticate unless they log out of the system. To fully take advantage of this setting, the value for `idle-timeout` has to be set to 0 also, so that the client does not time out if the maximum idle time is reached. If the `idle-timeout` is not set to the infinite value, the system will log out if it reaches the limit set, regardless of the `auth-timeout` setting.

Configuring authentication of remote IPsec VPN users

An IPsec VPN on a FortiGate unit can authenticate remote users through a dialup group. The user account name is the peer ID and the password is the pre-shared key.

Authentication through user groups is supported for groups containing only local users. To authenticate users using a RADIUS or LDAP server, you must configure XAUTH settings. See Configuring XAuth authentication.

To configure user group authentication for dialup IPsec - web-based manager:

1. Configure the dialup users who are permitted to use this VPN. Create a user group with **Type** set to **Firewall** and add them to it.
For more information, see [Users and user groups on page 181](#)
2. Go to **VPN > IPsec Wizard**, select **Remote Access**, choose a name for the VPN, and enter the following information.

Incoming Interface	Select the incoming interface name.
Authentication Method	List of authentication methods available for users. Select Pre-shared Key and enter the pre-shared key.
User Group	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.

To configure user group authentication for dialup IPsec - CLI example:

The `peertype` and `usrgrp` options configure user group-based authentication.

```
config vpn ipsec phase1
edit office_vpn
set interface port1
set type dynamic
set psksecret yORRAzltNGhzgtV32jend
set proposal 3des-sha1 aes128-sha1
set peertype dialup
set usrgrp Group1
end
```

Configuring XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit asks the user for a username and password. It then forwards the user's credentials (the password is encrypted) to an external RADIUS or LDAP server for verification.

XAuth can be used in addition to or in place of IPsec phase 1 peer options to provide access security through an LDAP or RADIUS authentication server. You must configure a dialup user group whose members are all externally authenticated.

To configure authentication for a dialup IPsec VPN - web-based manager:

1. Configure the users who are permitted to use this VPN. Create a user group and add the users to the group. For more information, see ["Users and user groups" on page 181](#).
2. Go to **VPN > IPsec Wizard**, select **Remote Access**, choose a name for the VPN, and enter the following information.

Incoming Interface	Select the incoming interface name.
Authentication Method	List of authentication methods available for users. Select Pre-shared Key and enter the pre-shared key.
User Group	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.
5. Go to **VPN > IPsec Tunnels**, edit the Tunnel just created, select **Convert To Custom Tunnel**, and edit **XAUTH** as following:

Type	Select PAP , CHAP , or AUTO . Use CHAP whenever possible. Use PAP with all implementations of LDAP and with other authentication servers that do not support CHAP, including some implementations of Microsoft RADIUS. Use AUTO with the Fortinet Remote VPN Client and where the authentication server supports CHAP but the XAuth client does not.
-------------	---

User Group

Select the user group that is to have access to the VPN. The list of user groups does not include any group that has members whose password is stored on the FortiGate unit.

6. Select OK.

For more information about XAUTH configuration, see the IPsec VPN chapter of the FortiOS Handbook.

To configure authentication for a dialup IPsec VPN - CLI example:

The `xauthtype` and `authusrgrp` fields configure XAuth authentication.

```
config vpn ipsec phase1
  edit office_vpn
    set interface port1
    set type dynamic
    set psksecret yORRAzltNGhzgtV32jend
    set proposal 3des-sha1 aes128-sha1
    set peertype dialup
    set xauthtype pap
    set usrgrp Group1
  end
```

Some parameters specific to setting up the VPN itself are not shown here. For detailed information about configuring IPsec VPNs, see the FortiOS Handbook IPsec VPN guide.

Configuring authentication of PPTP VPN users and user groups

Configuration of a PPTP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

To configure authentication for a PPTP VPN

1. Configure the users who are permitted to use this VPN. Create a security user group and add them to it. For more information, see [Users and user groups on page 181](#).
2. Configure the PPTP VPN in the CLI as in this example.

```
config vpn pptp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgrp PPTP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to PPTP clients.

Configure a security policy. The source interface is the one through which the clients will connect. The source address is the PPTP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Configuring authentication of L2TP VPN users/user groups

Configuration of a L2TP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

To configure authentication for a L2TP VPN

1. Configure the users who are permitted to use this VPN. Create a user group and add them to it. For more information, see [Users and user groups on page 181](#).
2. Configure the L2TP VPN in the CLI as in this example.

```
config vpn l2tp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgroup L2TP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to L2TP clients.

3. Configure a security policy. The source interface is the one through which the clients will connect. The source address is the L2TP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Captive portals

A captive portal is a convenient way to authenticate web users on wired or WiFi networks.

This section describes:

- [Introduction to captive portals](#)
- [Configuring a captive portal](#)
- [Customizing captive portal pages](#)

Introduction to captive portals

You can authenticate your users on a web page that requests the user's name and password. Until the user authenticates successfully, the authentication page is returned in response to any HTTP request. This is called a captive portal.

After successful authentication, the user accesses the requested URL and can access other web resources, as permitted by security policies. Optionally, the captive portal itself can allow web access to only the members of specified user group.

The captive portal can be hosted on the FortiGate unit or on an external authentication server. You can configure captive portal authentication on any network interface, including WiFi and VLAN interfaces.

When a captive portal is configured on a WiFi interface, the access point initially appears open. The wireless client can connect to the access point with no security credentials, but sees only the captive portal authentication page.

WiFi captive portal types:

- **Authentication** — until the user enters valid credentials, no communication beyond the AP is permitted.
- **Disclaimer + Authentication** — immediately after successful authentication, the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding.
- **Disclaimer Only** — the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding. The authentication page is not presented.
- **Email Collection** — the portal presents a page requesting the user's email address, for the purpose of contacting the person in future. This is often used by businesses who provide free WiFi access to their customers. The authentication page is not presented.

Configuring a captive portal

Captive portals are configured on network interfaces. On a physical (wired) network interface, you edit the interface configuration in **Network > Interfaces** and set **Security Mode** to **Captive Portal**. A WiFi interface does not exist until the WiFi SSID is created. You can configure a WiFi captive portal at the time that you create the SSID. Afterwards, the captive portal settings will also be available by editing the WiFi network interface in **Network > Interfaces**.

To configure a wired Captive Portal - web-based manager:

1. Go to **Network > Interfaces** and edit the interface to which the users connect.
2. In **Security Mode** select **Captive Portal**.

Security Mode	Captive Portal ▼
Authentication Portal	<input checked="" type="radio"/> Local <input type="radio"/> External
User Groups	Use Groups from Policies ▼
Exempt List	Click to set... ▼
Customize Portal Messages	<input type="checkbox"/>

3. Enter

Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups or select Use Groups from Policies , which permits the groups specified in the security policy. Use Groups from Policies is not available in WiFi captive portals.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Enable, then select Edit. See Customizing captive portal pages on page 235 .

4. Select **OK**.**To configure a WiFi captive portal - web-based manager:**

- Go to **WiFi & Switch Controller > SSID** and create your SSID.
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
- In **Security Mode**, select **Captive Portal**.

WiFi Settings	
SSID	fortinet
Security Mode	Captive Portal ▼
Client Limit	<input type="checkbox"/>
Portal Type	<input checked="" type="radio"/> Authentication <input type="radio"/> Disclaimer + Authentication <input type="radio"/> Disclaimer Only <input type="radio"/> Email Collection
Authentication Portal	<input type="radio"/> Local <input checked="" type="radio"/> External example.com/captive/
User Groups	<input type="text" value="+"/> +
Exempt Sources	<input type="text" value="+"/> +
Exempt Destinations/Services	<input type="text" value="+"/> +
Redirect after Captive Portal	<input checked="" type="radio"/> Original Request <input type="radio"/> Specific URL

3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection. See Introduction to captive portals on page 233 .
Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the link of the portal page that you want to modify. See "Captive portals" on page 235 .

4. Select **OK**.

Exemption from the captive portal

A captive portal requires all users on the interface to authenticate. But some devices are not able to authenticate. You can create an exemption list of these devices. For example, a printer might need to access the Internet for firmware upgrades. Using the CLI, you can create an exemption list to exempt all printers from authentication.

```
config user security-exempt-list
  edit r_exempt
    config rule
      edit 1
        set devices printer
      end
    end
  end
```

IPv6 and captive portals

Captive portal supports IPv6. Host name and address commands are available under `config auth setting`:

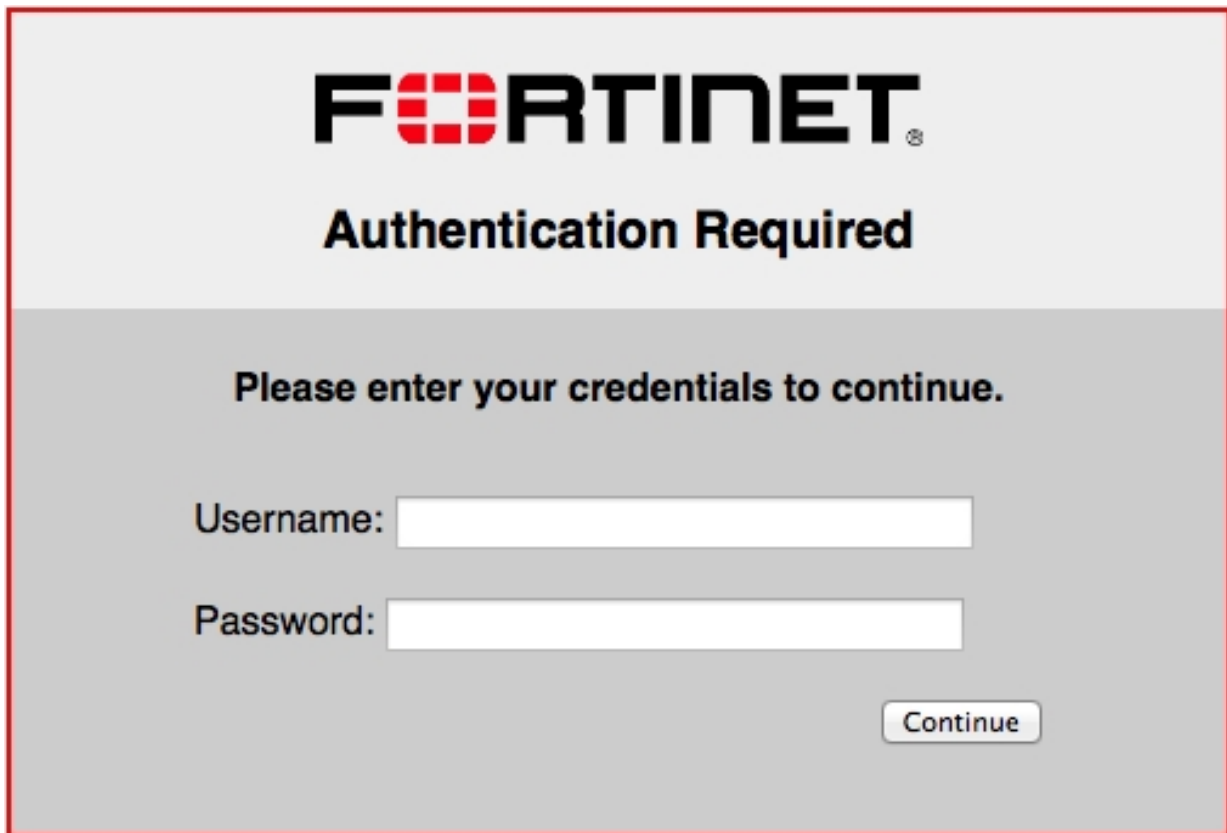

```
config auth setting
  set captive-portal6      --> IPv6 captive portal host name
  set captive-portal-ip6   --> Captive portal IPv6 address
end
```

Customizing captive portal pages

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting **Customize Portal Messages**. Each SSID can have its own unique portal content.

The captive portal contains the following default web pages:

- **Login page**—requests user credentials

The image shows a Fortinet captive portal login page. At the top, the Fortinet logo is displayed in black and red. Below the logo, the text "Authentication Required" is centered in a bold, black font. Underneath this, a message "Please enter your credentials to continue." is centered. There are two input fields: "Username:" followed by a white text box, and "Password:" followed by a white text box. A "Continue" button is located at the bottom right of the form area.

Typical modifications for this page would be to change the logo and modify some of the text.

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line "Please enter your credentials to continue" is provided by the `%%QUESTION%%` tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.

The image shows a web page for Fortinet authentication. At the top, the Fortinet logo is displayed in black and red. Below the logo, the text "Authentication Failed" is centered in a bold, black font. Underneath this, a message reads "Firewall Authentication failed. Please try again." in a bold, black font. Below the message, there are two input fields: "Username:" followed by a white text box, and "Password:" followed by a white text box. At the bottom right of the form, there is a button labeled "Continue". The entire form is enclosed in a red border.

The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line “Firewall authentication failed. Please try again.” is provided by the `%%FAILED_MESSAGE%%` tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Disclaimer page**—is a statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding. (WiFi or SSL VPN only)

Terms and Disclaimer Agreement

You are about to access Internet content that is not under the control of the network access provider. The network access provider is therefore not responsible for any of these sites, their content or their privacy policies. The network access provider and its staff do not endorse nor make any representations about these sites, or any information, software or other products or materials found there, or any results that may be obtained from using them. If you decide to access any Internet content, you do this entirely at your own risk and you are responsible for ensuring that any accessed material does not infringe the laws governing, but not exhaustively covering, copyright, trademarks, pornography, or any other material which is slanderous, defamatory or might cause offence in any other way.

Do you agree to the above terms?

- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

Changing images in portal messages

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

To import a logo file:

1. Go to **System > Replacement Messages** and select **Manage Images**.
2. Select **Create New**.
3. Enter a **Name** for the logo and select the appropriate **Content Type**.
The file must not exceed 24 Kilo bytes.
4. Select **Browse**, find your logo file and then select **Open**.
5. Select **OK**.

To specify the new logo in the replacement message:

1. Go to **Network > Interfaces** and edit the interface.
The **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
 - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
 - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. In the HTML message text, find the %%IMAGE tag.
By default it specifies the Fortinet logo: %%IMAGE:logo_fw_auth%%
4. Change the image name to the one you provided for your logo.
The tag should now read, for example, %%IMAGE:mylogo%%
5. Select **Save**.
6. Select **OK**.

Modifying text in portal messages

Generally, you can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. You should not remove any tags because they may carry information that the FortiGate unit needs. See the preceding section for any exceptions to this rule for particular pages.

To modify portal page text

1. Go to **Network > Interfaces** and edit the interface.
The SSID **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
 - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
 - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. Edit the HTML message text, then select **Save**.
4. Select **OK**.

Configuring disclaimer page for ethernet interface captive portals

While you can customize a disclaimer page for captive portals that connect via WiFi, the same can be done for wired connections. However, this can only be configured on the CLI Console, and only without configuring user groups.

When configuring a captive portal through the CLI, you may set `security-groups` to a specific user group. The result of this configuration will show an authentication form to users who wish to log in to the captive portal—**not** a disclaimer page. If you do not set any `security-groups` in your configuration, an "Allow all" status will be in effect, and the disclaimer page will be displayed for users.

The example CLI configuration below shows setting up a captive portal interface without setting security-groups, resulting in a disclaimer page for users:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 172.16.101.1 255.255.255.0
    set allowaccess ping https ssh snmp http
    set type physical
    set explicit-web-proxy enable
    set alias "LAN"
    set security-mode captive-portal
    set snmp-index 1
  next
end
```

Certificate-based authentication

This section provides an overview of how the FortiGate unit verifies the identities of administrators, SSL VPN users, or IPsec VPN peers using X.509 security certificates.

The following topics are included in this section:

- [What is a security certificate?](#)
- [Certificates overview](#)
- [Managing X.509 certificates](#)
- [Configuring certificate-based authentication](#)
- [Support for per-VDOM certificates](#)
- [Example — Generate a CSR on the FortiGate unit](#)
- [Example — Generate and Import CA certificate with private key pair on OpenSSL](#)
- [Example — Generate an SSL certificate in OpenSSL](#)

What is a security certificate?

A security certificate is a small text file that is part of a third-party generated public key infrastructure (PKI) to help guarantee the identity of both the user logging on and the web site they where they are logging in.

A certificate includes identifying information such as the company and location information for the web site, as well as the third-party company name, the expiry date of the certificate, and the public key.

FortiGate units use X.509 certificates to authenticate single sign-on (SSO) for users. The X.509 standard has been in use since before 2000, but has gained popularity with the Internet's increased popularity. X.509 v3 is defined in RFC 5280 and specifies standard formats for public key certificates, certificate revocation lists, and a certification path validation algorithm. The unused earlier X.509 version 1 was defined in RFC 1422.

The main difference between X.509 and PGP certificates is that where in PGP anyone can sign a certificate, for X.509 only a trusted authority can sign certificates. This limits the source of certificates to well known and trustworthy sources. Where PGP is well suited for one-to-one communications, the X.509 infrastructure is intended to be used in many different situations including one-to-many communications. Some common filename extensions for X.509 certificates are listed below.

Common certificate filename extensions

Filetype	Format name	Description
.pem	Privacy Enhanced Mail (PEM)	Base64 encoded DER certificate, that uses: “-----BEGIN CERTIFICATE-----” and “-----END CERTIFICATE-----”
.cer .crt .der	Security Certificate	Usually binary DER form, but Base64-encoded certificates are common too.
.p7b .p7c		Structure without data, just certificates or CRLs. PKCS#7 is a standard for signing or encrypting (officially called “enveloping”) data.
.p12	PKCS#12	May contain certificate(s) (public) and private keys (password protected).
.pfx	personal information exchange (PFX)	Older format. Came before PKCS#12. Usually today data is in PKCS#12 format.

Certificates overview

Certificates play a major role in authentication of clients connecting to network services via HTTPS, both for administrators and SSL VPN users. Certificate authentication is optional for IPsec VPN peers.

This section includes:

- [Certificates and protocols](#)
- [IPsec VPNs and certificates](#)
- [Certificate types on the FortiGate unit](#)

Public CA certificates found on the FortiGate are provided through firmware upgrades and installations.

Certificates and protocols

There are a number of protocols that are commonly used with certificates including SSL and HTTPS, and other certificate-related protocols.

SSL and HTTPS

The secure HTTP (HTTPS) protocol uses SSL. Certificates are an integral part of SSL. When a web browser connects to the FortiGate unit via HTTPS, a certificate is used to verify the FortiGate unit's identity to the client. Optionally, the FortiGate unit can require the client to authenticate itself in return.

By default, the FortiGate unit uses a self-signed security certificate to authenticate itself to HTTPS clients. When the certificate is offered, the client browser displays two security messages.

- The first message prompts users to accept and optionally install the FortiGate unit's self-signed security certificate. If the user does not accept the certificate, the FortiGate unit refuses the connection. When the user accepts the certificate, the FortiGate login page is displayed, and the credentials entered by the user are encrypted before they are sent to the FortiGate unit. If the user chooses to install the certificate, the prompt is not displayed again.
- Just before the FortiGate login page is displayed, a second message informs users that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit redirects the connection (away from the distinguished name recorded in the self-signed certificate) and can be ignored.

Optionally, you can install an X.509 server certificate issued by a certificate authority (CA) on the FortiGate unit. You can then configure the FortiGate unit to identify itself using the server certificate instead of the self-signed certificate.

For more information, see the FortiOS Handbook SSL VPN guide.

After successful certificate authentication, communication between the client browser and the FortiGate unit is encrypted using SSL over the HTTPS link.

Certificate-related protocols

There are multiple protocols that are required for handling certificates. These include the Online Certificate Status Protocol (OCSP), Simple Certificate Enrollment Protocol (SCEP), Server-based Certificate Validation Protocol (SCVP), and Certificate Management Protocol (CMP).

Online Certificate Status Protocol

Online Certificate Status Protocol (OCSP) allows the verification of X.509 certificate expiration dates. This is important to prevent hackers from changing the expiry date on an old certificate to a future date.

Normally certificate revocation lists (CRLs) are used, but OCSP is an alternate method available. However a CRL is a public list, and some companies may want to avoid the public exposure of their certificate structure even if it is only invalid certificates.

The OSCP check on the certificate's revocation status is typically carried out over HTTP with a request-response format. The authority responding can reply with a status of good, revoked, or unknown for the certificate in question.

Simple Certificate Enrollment Protocol

Simple Certificate Enrollment Protocol (SCEP) is an automated method of signing up for certificates. Typically this involves generating a request you send directly to the SCEP service, instead of generating a file request that may or may not be signed locally.

Server-based Certificate Validation Protocol

Server-based Certificate Validation Protocol (SCVP) is used to trace a certificate back to a valid root level certificate. This ensures that each step along the path is valid and trustworthy.

Certificate Management Protocol version 2

Certificate Management Protocol version 2 (CMPv2) is an enrollment and revocation protocol for certificates.

IPsec VPNs and certificates

Certificate authentication is a more secure alternative to pre-shared key (shared secret) authentication for IPsec VPN peers. Unlike administrators or SSL VPN users, IPsec peers use HTTP to connect to the VPN gateway configured on the FortiGate unit. The VPN gateway configuration can require certificate authentication before it permits an IPsec tunnel to be established. See [Authenticating IPsec VPN users with security certificates on page 256](#).

Certificate types on the FortiGate unit

There are different types of certificates available that vary depending on their intended use. FortiOS supports local, remote, CA, and CRL certificates.

Local certificates

Local certificates are issued for a specific server, or web site. Generally they are very specific, and often for an internal enterprise network. For example a personal web site for John Smith at www.example.com (such as <http://www.example.com/home/jsmith>) would have its own local certificate.

These can optionally be just the certificate file, or also include a private key file and PEM passphrase for added security.

For information about generating a certificate request, see [Generating a certificate signing request on page 246](#). For information about installing a local certificate, see [Obtaining and installing a signed server certificate from an external CA on page 249](#).

Remote certificates

Remote certificates are public certificates without a private key. For dynamic certificate revocation, you need to use an Online Certificate Status Protocol (OCSP) server. The OCSP is configured in the CLI only. Installed Remote (OCSP) certificates are displayed in the Remote Certificates list. You can select **Import** to install a certificate from the management PC.

CA root certificates

CA root certificates are similar to local certificates, however they apply to a broader range of addresses or to whole company; they are one step higher up in the organizational chain. Using the local certificate example, a CA root certificate would be issued for all of www.example.com instead of just the smaller single web page.

Certificate revocation list

Certificate revocation list (CRL) is a list of certificates that have been revoked and are no longer usable. This list includes certificates that have expired, been stolen, or otherwise compromised. If your certificate is on this list, it will not be accepted. CRLs are maintained by the CA that issues the certificates and includes the date and time when the next CRL will be issued as well as a sequence number to help ensure you have the most current version of the CRL.

Certificate signing

The trust in a certificate comes from the authority that signs it. For example if VeriSign signs your CA root certificate, it is trusted by everyone. While these certificates are universally accepted, it is cumbersome and expensive to have all certificates on a corporate network signed with this level of trust.

With self-signed certificates nobody, except the other end of your communication, knows who you are and therefore they do not trust you as an authority. However this level is useful for encryption between two points — neither point may care about who signed the certificate, just that it allows both points to communicate. This is very useful for internal networks and communications.

A general rule is that CA signed certificates are accepted and sometimes required, but it is easier to self-sign certificates when you are able.

For more on the methods of certificate signing see [Generating a certificate signing request on page 246](#).

BIOS certificate compatibility

FortiOS supports backwards compatibility between BIOS version 4 and BIOS version 3.

BIOS V4 certificates:

- Fortinet_CA
- Fortinet_Sub_CA
- Fortinet_Factory

BIOS V3 certificates:

- Fortinet_CA_Backup
- Fortinet_Factory_Backup

When FortiOS connects to FortiGuard, FortiCloud, FortiManager, FortiAnalyzer, FortiSandbox as a client, the BIOS certificate **Fortinet_Factory** will be the default client certificate. When the server returns its certificate (chain) back, FortiOS looks up the issuer of the server certificate and either keeps client certificate as is or switches to the BIOS certificate **Fortinet_Factory_Backup**. This process occurs in one handshake.

When FortiOS connects to FortiCare, the BIOS certificate **Fortinet_Factory** is the only client certificate and Server Name Indication (SNI) is set. There is no switchover of certificate during SSL handshake.

When FortiOS acts as a server when connected by FortiExtender, FortiSwitch, FortiAP, etc., **Fortinet_Factory** is the default server certificate. FortiOS detects SNI in client hello, and if no SNI is found or if the CN in SNI is different from the CN of **Fortinet_CA**, it switches to use the **Fortinet_Factory_Backup**.

Managing X.509 certificates

Managing security certificates is required due to the number of steps involved in both having a certificate request signed, and then distributing the correct files for use.

You use the FortiGate unit or CA software such as OpenSSL to generate a certificate request. That request is a text file that you send to the CA for verification, or alternately you use CA software to self-validate. Once validated, the certificate file is generated and must be imported to the FortiGate unit before it can be used. These steps are explained in more detail later in this section.

This section provides procedures for generating certificate requests, installing signed server certificates, and importing CA root certificates and CRLs to the FortiGate unit.

For information about how to install root certificates, CRLs, and personal or group certificates on a remote client browser, refer to your browser's documentation.

As a requirement of Network Device Collaborative Protection Profile (NDcPP), FortiOS supports and handles the use of wildcards for the following certificate reference parameters:

- Subject Alternative Name (SAN)
- Common Name (CN)

This section includes:

- [Generating a certificate signing request](#)
- [Generating certificates with CA software](#)
- [Obtaining and installing a signed server certificate from an external CA](#)
- [Installing a CA root certificate and CRL to authenticate remote clients](#)
- [ExtendedKeyUsage for x.509 certificates](#)

Generating a certificate signing request

Whether you create certificates locally with a software application or obtain them from an external certificate service, you will need to generate a certificate signing request (CSR).

When you generate a CSR, a private and public key pair is created for the FortiGate unit. The generated request includes the public key of the FortiGate unit and information such as the FortiGate unit's public static IP address, domain name, or email address. The FortiGate unit's private key remains confidential on the FortiGate unit.

After you submit the request to a CA, the CA will verify the information and register the contact information on a digital certificate that contains a serial number, an expiration date, and the public key of the CA. The CA will then sign the certificate, and you install the certificate on the FortiGate unit.

The Certificate Request Standard is a public key cryptography standard (PKCS) published by RSA, specifically PKCS10 which defines the format for CSRs. This is defined in RFC 2986.

To generate a certificate request in FortiOS - web-based manager:

1. Go to **System > Certificates**.
2. Select **Generate**.
3. In the **Certificate Name** field, enter a unique meaningful name for the certificate request. Typically, this would be the hostname or serial number of the FortiGate unit or the domain of the FortiGate unit such as example.com.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

Prior to FortiOS 5.4, passwords for local certificates that were generated via either SCEP or CLI could not have their passwords reset. Passwords can be set in the CLI using the following command:

```
config vpn certificate local
edit <name>
set password <password>
next
end
```

4. Enter values in the **Subject Information** area to identify the FortiGate unit:
 - If the FortiGate unit has a static IP address, select **Host IP** and enter the public IP address of the FortiGate unit. If the FortiGate unit does not have a public IP address, use an email address (or fully qualified domain name (FQDN) if available) instead.
 - If the FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service, use a FQDN if available to identify the FortiGate unit. If you select **Domain Name**, enter the FQDN of the FortiGate unit. Do not include the protocol specification (http://) or any port number or path names.

If a domain name is not available and the FortiGate unit subscribes to a dynamic DNS service, an “unable to verify certificate” type message may be displayed in the user’s browser whenever the public IP address of the FortiGate unit changes.

- If you select **E-Mail**, enter the email address of the owner of the FortiGate unit.
5. Enter values in the **Optional Information** area to further identify the FortiGate unit.

Organization Unit	Name of your department. You can enter a series of OUs up to a maximum of 5. To add or remove an OU, use the plus (+) or minus (-) icon.
Organization	Legal name of your company or organization.
Locality (City)	Name of the city or town where the FortiGate unit is installed.
State/Province	Name of the state or province where the FortiGate unit is installed.
Country	Select the country where the FortiGate unit is installed.
e-mail	Contact email address.
Subject Alternative Name	<p>Optionally, enter one or more alternative names for which the certificate is also valid. Separate names with a comma. A name can be:</p> <ul style="list-style-type: none"> • e-mail address • IP address • URI • DNS name (alternatives to the Common Name) • directory name (alternatives to the Distinguished Name) <p>You must precede the name with the name type. Examples:</p> <p>IP: 1.1.1.1 email: test@fortinet.com email: my@other.address URI: http://my.url.here/</p>
Password for private key	Option to export local certificate and its private key in password protected p12.

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. From the **Key Size** list, select **1024 Bit**, **1536 Bit**, **2048 Bit**, **4096 Bit** or **secp256r1**, **secp384r1**, **secp521r1** respectively. Larger keys are slower to generate but more secure.

8. In **Enrollment Method**, you have two methods to choose from. Select **File Based** to generate the certificate request, or **Online SCEP** to obtain a signed SCEP-based certificate automatically over the network. For the SCEP method, enter the URL of the SCEP server from which to retrieve the CA certificate, and the CA server challenge password.
 9. Select **OK**.
 10. The request is generated and displayed in the **Local Certificates** list with a status of `PENDING`.
 11. Select the **Download** button to download the request to the management computer.
 12. In the **File Download** dialog box, select **Save** and save the Certificate Signing Request on the local file system of the management computer.
 13. Name the file and save it on the local file system of the management computer.
- The certificate request is ready for the certificate authority to be signed.

Generating certificates with CA software

CA software allows you to generate unmanaged certificates and CA certificates for managing other certificates locally without using an external CA service. Examples of CA software include `ssl-ca` from OpenSSL (available for Linux, Windows, and Mac) or `gensslcert` from SuSE, MS Windows Server 2000 and 2003 come with a CA as part of their certificate services, and in MS Windows 2008 CA software can be installed as part of the Active Directory installation. See [Example — Generate and Import CA certificate with private key pair on OpenSSL on page 259](#).

The general steps for generating certificates with CA software are

1. Install the CA software as a stand-alone root CA.
2. Provide identifying information for your self-administered CA.

While following these steps, the methods vary slightly when generating server certificates, CA certificates, and PKI certificates.

Server certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS10 or PKCS7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with `.CER` extension
4. Upload the certificate file to the FortiGate unit Local Certificates page (type is Certificate).

CA certificate

1. Retrieve the CA Certificate from the CA software as a DER encoded file.
2. Import the CA certificate file to the FortiGate unit at **System > Certificates** and select **Import > Certificates**.

PKI certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS#10 or PKCS#7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with `.CER` extension.
4. Install the certificate in the user's web browser or IPsec VPN client as needed.

Obtaining and installing a signed server certificate from an external CA

To obtain a signed server certificate for a FortiGate unit, you must send a request to a CA that provides digital certificates that adhere to the X.509 standard. The FortiGate unit provides a way for you to generate the request.

To submit the certificate signing request (file-based enrollment):

1. Using the web browser on the management computer, browse to the CA web site.
2. Follow the CA instructions for a base-64 encoded PKCS#10 certificate request and upload your certificate request.
3. Follow the CA instructions to download their root certificate and CRL.
When you receive the signed server certificate from the CA, install the certificate on the FortiGate unit.

To install or import the signed server certificate - web-based manager

1. On the FortiGate unit, go to **System > Certificates** and select **Import > Local Certificates**.
2. From **Type**, select **Local Certificate**.
3. Select **Browse**, browse to the location on the management computer where the certificate was saved, select the certificate, and then select **Open**.
4. Select **OK**, and then select **Return**.

Installing a CA root certificate and CRL to authenticate remote clients

When you apply for a signed personal or group certificate to install on remote clients, you can obtain the corresponding root certificate and CRL from the issuing CA. When you receive the signed personal or group certificate, install the signed certificate on the remote client(s) according to the browser documentation. Install the corresponding root certificate (and CRL) from the issuing CA on the FortiGate unit according to the procedures given below.

To install a CA root certificate

1. After you download the root certificate of the CA, save the certificate on the management computer. Or, you can use online SCEP to retrieve the certificate.
2. On the FortiGate unit, go to **System > Certificates** and select **Import > CA Certificates**.
3. Do one of the following:
 - To import using SCEP, select **SCEP**. Enter the URL of the SCEP server from which to retrieve the CA certificate. Optionally, enter identifying information of the CA, such as the filename.
 - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the certificate has been saved. Select the certificate, and then select **Open**.
5. Select **OK**, and then select **Return**.

The system assigns a unique name to each CA certificate. The names are numbered consecutively (CA_Cert_1, CA_Cert_2, CA_Cert_3, and so on).

To import a certificate revocation list

A Certificate Revocation List (CRL) is a list of the CA certificate subscribers paired with certificate status information. The list contains the revoked certificates and the reason(s) for revocation. It also records the certificate issue dates and the CAs that issued them.

When configured to support SSL VPNs, the FortiGate unit uses the CRL to ensure that the certificates belonging to the CA and remote peers or clients are valid. The CRL has an “effective date” and a “next update” date. The interval is typically 7 days (for Microsoft CA). FortiOS will update the CRL automatically. Also, there is a CLI command to specify an “update-interval” in seconds. Recommendation should be 24 hours (86400 seconds) but depends on company security policy.

1. After you download the CRL from the CA web site, save the CRL on the management computer.
2. Go to **System > Certificates** and select **Import > CRL**.
3. Do one of the following:
 - To import using an HTTP server, select **HTTP** and enter the URL of the HTTP server.
 - To import using an LDAP server see this KB [article](#).
 - To import using an SCEP server, select **SCEP** and select the Local Certificate from the list. Enter the URL of the SCEP server from which the CRL can be retrieved.
 - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the CRL has been saved. Select the CRL and then select **Open**.
5. Select **OK**, and then select **Return**.

To import a PKCS12 certificate from the CLI

The following CLI syntax can be entered to import a local certificate file:

```
execute vpn certificate local import tftp <file name> <tftp ip address> <file type> <Enter  
for 'cer'>|<password for 'p12'>
```

For example:

```
execute vpn certificate local import tftp FGTF-extern.p12 10.1.100.253 p12 123456
```

In addition, the following CLI syntax can be entered to update certificate bundles from an FTP or TFTP server:

```
execute vpn certificate ca import bundle <file-name.pkg> <ftp/tftp-server-ip>
```

ExtendedKeyUsage for x.509 certificates

As per Network Device Collaborative Protection Profile (NDcPP) v1.0 requirements, server certificates used for TLS connections between FortiGate and FortiAnalyzer have the "Server Authentication" and "Client Authentication" extendedKeyUsage fields in FIPS/CC mode.

The following CLI command is available under `log fortianalyzer` setting to allow you to specify the certificate used to communicate with FortiAnalyzer.

CLI syntax

```
config log fortianalyzer setting  
  set certificate <name>  
end
```

Troubleshooting certificates

There are times when there are problems with certificates — a certificate is seen as expired when its not, or it can't be found. Often the problem is with a third party web site, and not FortiOS. However, some problems can be traced back to FortiOS such as DNS or routing issues.

Enable and disable SHA1 algorithm in SSH key exchanges

In order to investigate your security and conduct compliance testing, a global option allows you to enable/disable SHA1 algorithm in SSH key exchange. Note that, the algorithm is enabled by default.

Syntax

```
config system global
  set ssh-key-sha1 {enable | disable}
end
```

Certificate incorrectly reported as expired

Certificates often are issued for a set period of time such as a day or a month, depending on their intended use. This ensures everyone is using up-to-date certificates. It is also more difficult for hackers to steal and use old certificates.

Reasons a certificate may be reported as expired include:

- It really has expired based on the “best before” date in the certificate
- The FortiGate unit clock is not properly set. If the FortiGate clock is fast, it will see a certificate as expired before the expiry date is really here.
- The requesting server clock is not properly set. A valid example is if your certificate is 2 hours from expiring, a server more than two time zones away would see the certificate as expired. Otherwise, if the server’s clock is set wrongly it will also have the same effect.
- The certificate was revoked by the issuer before the expiry date. This may happen if the issuer believes a certificate was either stolen or misused. Its possible it is due to reasons on the issuer’s side, such as a system change or such. In either case it is best to contact the certificate issuer to determine what is happening and why.

A secure connection cannot be completed (certificate cannot be found)

Everyone who uses a browser has encountered a message such as *This connection is untrusted*. Normally when you try to connect securely to a web site, that web site will present its valid certificate to prove their identity is valid. When the web site’s certificate cannot be verified as valid, the message appears stating *This connection is untrusted* or something similar. If you usually connect to this web site without problems, this error could mean that someone is trying to impersonate or hijack the web site, and best practices dictates you not continue.

Reasons a web site’s certificate cannot be validated include:

- The web site uses an unrecognized self-signed certificate. These are not secure because anyone can sign them. If you accept self-signed certificates you do so at your own risk. Best practices dictate that you must confirm the ID of the web site using some other method before you accept the certificate.
- The certificate is valid for a different domain. A certificate is valid for a specific location, domain, or sub-section of a domain such as one certificate for `support.example.com` that is not valid for `marketing.example.com`. If you encounter this problem, contact the webmaster for the web site to inform them of the problem.
- There is a DNS or routing problem. If the web site’s certificate cannot be verified, it will not be accepted. Generally to be verified, your system checks with the third party certificate signing authority to verify the certificate is valid. If you cannot reach that third party due to some DNS or routing error, the certificate will not be verified.
- Firewall is blocking required ports. Ensure that any firewalls between the requesting computer and the web site allow the secure traffic through the firewall. Otherwise a hole must be opened to allow it through. This includes ports such as 443 (HTTPS) and 22 (SSH).

Online updates to certificates and CRLs

If you obtained your local or CA certificate using SCEP, you can configure online renewal of the certificate before it expires. Similarly, you can receive online updates to CRLs.

Local certificates

In the `config vpn certificate local` command, you can specify automatic certificate renewal. The relevant fields are:

<code>scep-url <URL_str></code>	The URL of the SCEP server. This can be HTTP or HTTPS. The following options appear after you add the <code><URL_str></code> .
<code>scep-password <password_str></code>	The password for the SCEP server.
<code>auto-regenerate-days <days_int></code>	How many days before expiry the FortiGate unit requests an updated local certificate. The default is 0, no auto-update.
<code>auto-regenerate-days-warning <days_int></code>	How many days before local certificate expiry the FortiGate generates a warning message. The default is 0, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate local
edit mycert
set scep-url http://scep.example.com/scep
set scep-server-password my_pass_123
set auto-regenerate-days 3
set auto-regenerate-days-warning 2
end
```

CA certificates

In the `config vpn certificate ca` command, you can specify automatic certificate renewal. The relevant fields are:

Variable	Description
<code>scep-url <URL_str></code>	The URL of the SCEP server. This can be HTTP or HTTPS.
<code>auto-update-days <days_int></code>	How many days before expiry the FortiGate unit requests an updated CA certificate. The default is 0, no auto-update.
<code>auto-update-days-warning <days_int></code>	How many days before CA certificate expiry the FortiGate generates a warning message. The default is 0, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate ca
edit mycert
set scep-url http://scep.example.com/scep
set auto-update-days 3
set auto-update-days-warning 2
```

```
end
```

Certificate revocation lists

If you obtained your CRL using SCEP, you can configure online updates to the CRL using the `config vpn certificate crl` command. The relevant fields are:

Variable	Description
<code>http-url <http_url></code>	URL of the server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
<code>scep-cert <scep_certificate></code>	Local certificate used for SCEP communication for CRL auto-update.
<code>scep-url <scep_url></code>	URL of the SCEP CA server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
<code>update-interval <seconds></code>	How frequently, in seconds, the FortiGate unit checks for an updated CRL. Enter 0 to update the CRL only when it expires. Not available for http URLs.
<code>update-vdom <update_vdom></code>	VDOM used to communicate with remote SCEP server for CRL auto-update.

In this example, an updated CRL is requested only when it expires.

```
config vpn certificate crl
  edit cert_crl
    set http-url http://scep.example.com/scep
    set scep-cert my-scep-cert
    set scep-url http://scep.ca.example.com/scep
    set update-interval 0
    set update-vdom root
  end
```

Backing up and restoring local certificates

The FortiGate unit provides a way to export and import a server certificate and the FortiGate unit's personal key through the CLI. If required (to restore the FortiGate unit configuration), you can import the exported file through the **System > Certificates** page of the web-based manager.

As an alternative, you can back up and restore the entire FortiGate configuration through the **System Information** widget on the Dashboard of the web-based manager. Look for **[Backup]** and **[Restore]** in the **System Configuration** row. The backup file is created in a FortiGate-proprietary format.

To export a server certificate and private key - CLI:

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate unit before you enter the command.

1. Connect to the FortiGate unit through the CLI.
2. Type the following command:

```
execute vpn certificate local export tftp <cert_name> <exp_filename> <tftp_ip>
<password>
```

where:

- <cert_name> is the name of the server certificate; typing ? displays a list of installed server certificates.
 - <exp_filename> is a name for the output file.
 - <tftp_ip> is the IP address assigned to the TFTP server host interface.
3. Move the output file from the TFTP server location to the management computer for future reference.

To import a server certificate and private key - web-based manager:

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **PKCS12 Certificate**.
3. Select **Browse**. Browse to the location on the management computer where the exported file has been saved, select the file, and then select **Open**.
4. In the **Password** field, type the password needed to upload the exported file.
5. Select **OK**, and then select **Return**.

To import a server certificate and private key - CLI:

1. Connect to the FortiGate unit through the CLI.
2. Type the following command:

```
execute vpn certificate local import tftp <file_name> <tftp_ip_address> <file_type> <Enter
for 'cer'>|<password for 'p12'>
```

For example:

```
execute vpn certificate local import tftp FGTF-extern.p12 10.1.100.253 p12 123456
```

To import separate server certificate and private key files - web-based manager

Use the following procedure to import a server certificate and the associated private key file when the server certificate request and private key were not generated by the FortiGate unit. The two files to import must be available on the management computer.

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **Certificate**.
3. Select the **Browse** button beside the **Certificate file** field. Browse to the location on the management computer where the certificate file has been saved, select the file, and then select **Open**.
4. Select the **Browse** button beside the **Key file** field. Browse to the location on the management computer where the key file has been saved, select the file, and then select **Open**.
5. If required, in the **Password** field, type the associated password, and then select **OK**.
6. Select **Return**.

Configuring certificate-based authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users.

In Microsoft Windows 7, you can use the certificate manager to keep track of all the different certificates on your local computer. To access certificate manager, in Windows 7 press the Windows key, enter “certmgr.msc” at the search prompt, and select the displayed match. Remember that in addition to these system certificates, many applications require you to register certificates with them directly.

To see FortiClient certificates, open the FortiClient Console, and select VPN. The VPN menu has options for My Certificates (local or client) and CA Certificates (root or intermediary certificate authorities). Use Import on those screens to import certificate files from other sources.

Authenticating administrators with security certificates

You can install a certificate on the management computer to support strong authentication for administrators. When a personal certificate is installed on the management computer, the FortiGate unit processes the certificate after the administrator supplies a username and password.

To enable strong administrative authentication:

- Obtain a signed personal certificate for the administrator from a CA and load the signed personal certificate into the web browser on the management computer according to the browser documentation.
- Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see [Installing a CA root certificate and CRL to authenticate remote clients on page 249](#)).
- Create a PKI user account for the administrator.
- Add the PKI user account to a firewall user group dedicated to PKI-authenticated administrators.
- In the administrator account configuration, select **PKI** as the account **Type** and select the **User Group** to which the administrator belongs.

Support exact match for subject and CN fields in peer user

In order to avoid any unintentional admin access by regular users, administrators can specify which way a peer user authenticates.

When searching for a matching certificate, use the commands below to control how to find matches in the certificate subject name (`subject-match`) or the cn attribute (`cn-match`) of the certificate subject name. This match can be any string (`substring`) or an exact match (`value`) of the cn attribute value.

To determine certificate subject name matches - CLI:

```
config vpn certificate setting
  edit <name>
    set subject-match {substring | value}
    set cn-match {substring | value}
  next
end
```

Authenticating SSL VPN users with security certificates

While the default self-signed certificates can be used for HTTPS connections, it is preferable to use the X.509 server certificate to avoid the redirection as it can be misinterpreted as possible session hijacking. However, the server certificate method is more complex than self-signed security certificates. Also the warning message is typically displayed for the initial connection, and future connections will not generate these messages.

X.509 certificates can be used to authenticate IPsec VPN peers or clients, or SSL VPN clients. When configured to authenticate a VPN peer or client, the FortiGate unit prompts the VPN peer or client to authenticate itself using the X.509 certificate. The certificate supplied by the VPN peer or client must be verifiable using the root CA certificate installed on the FortiGate unit in order for a VPN tunnel to be established.

To enable certificate authentication for an SSL VPN user group:

1. Install a signed server certificate on the FortiGate unit and install the corresponding root certificate (and CRL) from the issuing CA on the remote peer or client.
2. Obtain a signed group certificate from a CA and load the signed group certificate into the web browser used by each user. Follow the browser documentation to load the certificates.
3. Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see [Installing a CA root certificate and CRL to authenticate remote clients on page 249](#)).
4. Create a PKI user for each SSL VPN user. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
5. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the SSL VPN users who are authenticated by certificate.
6. Go to **Policy & Objects > IPv4 Policy**.
7. Edit the SSL-VPN security policy.
8. Select the user group created earlier in the **Source User(s)** field.
9. Select **OK**.

Authenticating IPsec VPN users with security certificates

To require VPN peers to authenticate by means of a certificate, the FortiGate unit must offer a certificate to authenticate itself to the peer.

To enable the FortiGate unit to authenticate itself with a certificate:

1. Install a signed server certificate on the FortiGate unit.
See [To install or import the signed server certificate - web-based manager on page 249](#).
2. Install the corresponding CA root certificate on the remote peer or client. If the remote peer is a FortiGate unit, see [To install a CA root certificate on page 249](#).
3. Install the certificate revocation list (CRL) from the issuing CA on the remote peer or client. If the remote peer is a FortiGate unit, see [To import a certificate revocation list on page 249](#).
4. In the VPN phase 1 configuration, set **Authentication Method** to **Signature** and from the **Certificate Name** list select the certificate that you installed in Step 1.

To authenticate a VPN peer using a certificate, you must install a signed server certificate on the peer. Then, on the FortiGate unit, the configuration depends on whether there is only one VPN peer or if this is a dialup VPN that can be multiple peers.

To configure certificate authentication of a single peer

1. Install the CA root certificate and CRL.
2. Create a PKI user to represent the peer. Specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. In the VPN phase 1 **Peer Options**, select **peer certificate** for **Accept Types** field and select the PKI user that you created in the **Peer certificate** field.

To configure certificate authentication of multiple peers (dialup VPN)

1. Install the corresponding CA root certificate and CRL.
2. Create a PKI user for each remote VPN peer. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the PKI users who will use the IPsec VPN.

In the VPN phase 1 **Peer Options**, select **peer certificate group** for **Accept Types** field and select the PKI user group that you created in the **Peer certificate group** field.

Support for per-VDOM certificates

The CA and local certificate configuration is available per-VDOM. When an admin uploads a certificate to a VDOM, it will only be accessible inside that VDOM. When an admin uploads a certificate to global, it will be accessible to all VDOMs and global.

There are factory default certificates such as Fortinet_CA_SSL, Fortinet_SSL, Fortinet_Wifi, and Fortinet_Factory. These certificates are moved to per-VDOM and automatically generated when a new VDOM is created.

The Fortinet_Firmware certificate has been removed and all the attributes that use Fortinet_Firmware now use Fortinet_Factory.

CLI changes

Two new attributes `range` and `source` have been added:

`range` can be global or per-VDOM, if the certificate file is imported from global, it is a global certificate. If the certificate file is imported from a VDOM, it is VDOM certificate.

`source` can be either `factory`, `user`, or `fortiguard`:

- `factory`: The factory certificate file with FortiOS version, this includes: Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, Fortinet_Factory.
- `user`: Certificate file imported by the user.
- `fortiguard`: Certificate file imported from FortiGuard.

```
config certificate local
  edit Fortinet_Factory
    set range {global | vdom}
    set source {factory | user | fortiguard}
  end
end
```

GUI changes

Global and new VDOMs have the following factory default certificates:

Name	Subject	Comments	Issuer	Expires	Status	Source	Ref.
Certificates (12)							
Fortinet_SSL_ECDSA	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 18:39:25 GMT	OK	Factory	0
Fortinet_SSL_ECDSA256	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 19:39:00 GMT	OK	Factory	1
Fortinet_SSL	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 18:39:24 GMT	OK	Factory	2

These certificates are created automatically when a new VDOM is created, with every VDOM having its own versions of these certificates.

Example — Generate a CSR on the FortiGate unit

This example follows all the steps required to create and install a local certificate on the FortiGate unit, without using CA software.

The FortiGate unit is called **myFortiGate60**, and is located at 10.11.101.101 (a private IP address) and <http://myfortigate.example.com>. Mr. John Smith (john.smith@myfortigate.example.com) is the IT administrator for this FortiGate unit, and the unit belongs to the Sales department located in Greenwich, London, England.

To generate a certificate request on the FortiGate unit - web-based manager:

1. Go to **System > Certificates**.
2. Select **Generate**.
3. In the **Certificate Name** field, enter `myFortiGate60`.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

Since the IP address is private, we will use the FQDN instead.

4. Select **Domain Name**, and enter `http://myfortigate.example.com`.
5. Enter values in the **Optional Information** area to further identify the FortiGate unit.

Organization Unit	Sales
Organization	Example.com
Locality (City)	Greenwich

State/Province	London
Country	England
e-mail	john.smith@myfortigate.example.com

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. If **RSA** is selected, set **Key Size** to **2048 Bit**. If **Elliptic Curve** is selected, set **Curve Name** to **secp256r1**.
8. In **Enrollment Method**, select **File Based** to generate the certificate request
9. Select **OK**.
The request is generated and displayed in the **Local Certificates** list with a status of **PENDING**.
10. Select the **Download** button to download the request to the management computer.
11. In the **File Download** dialog box, select **Save** and save the Certificate Signing Request on the local file system of the management computer.
12. Name the file and save it on the local file system of the management computer.

Example — Generate and Import CA certificate with private key pair on OpenSSL

This example explains how to generate a certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

Assumptions

Before starting this procedure, ensure that you have downloaded and installed OpenSSL on Windows. One source is: <http://www.slproweb.com/products/Win32OpenSSL.html>.

Generating and importing the CA certificate and private key

The two following procedures will generate a CA certificate file and private key file, and then import it to the FortiGate unit as a local certificate.

To generate the private key and certificate

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the command:

```
cd c:\OpenSSL-Win32\bin
```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet123.

```
openssl genrsa -aes256 -out fgtpcapriv.key 2048
```

This command generates an RSA AES256 2048-bit encryption key.

3. The following command will generate the certificate using the key from the previous step.

```
openssl req -new -x509 -days 3650 -extensions v3_ca -key fgtpcapriv.key -out fgtpca.crt
```

This step generates an X509 CA certificate good for 10 years that uses the key generated in the

previous step. The certificate filename is `fgtca.crt`.

You will be prompted to enter information such as PEM Pass Phrase from the previous step, Country Name, State, Organization Name, Organizational Unit (such as department name), Common Name (the FQDN), and Email Address.

To import the certificate to the FortiGate unit - web-based manager:

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.
Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtca.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtcapriv.key`.
6. For **Password**, enter the PEM Pass Phrase you entered earlier, such as `fortinet123`.
7. Select **OK**.

The Certificate will be added to the list of Local Certificates and be ready for use. It will appear in the list as the filename you uploaded — `fgtca`. You can add comments to this certificate to make it clear where its from and how it is intended to be used. If you download the certificate from FortiOS, it is a `.CER` file.

It can now be used in [Authenticating IPsec VPN users with security certificates on page 256](#), and [Authenticating SSL VPN users with security certificates on page 256](#).

Example — Generate an SSL certificate in OpenSSL

This example explains how to generate a CA signed SSL certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

In this example, you will:

- Generate a CA signed SSL certificate
- Generate a self-signed SSL certificate
- Import the SSL certificate into FortiOS

Assumptions

- Before starting this procedure, ensure that you have downloaded and installed OpenSSL on MS Windows. One download source is <http://www.slproweb.com/products/Win32OpenSSL.html>.

Generating a CA signed SSL certificate

This procedure assumes that you have already completed [Example — Generate and Import CA certificate with private key pair on OpenSSL on page 259](#) successfully.

To generate the CA signed SSL certificate:

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.

```
openssl genrsa -aes256 -out fgtssl.key 2048
```

This command generates an RSA AES256 2048-bit encryption key.

3. Create a certificate signing request for the SSL certificate. This step requires you to enter the information listed in step 3 of the previous example — [To generate the private key and certificate](#). You can leave the Challenge Password blank.

```
openssl req -new -sha256 -key fgtssl.key -out fgtssl.csr
```

Most Certificate Authorities will ignore the value that is set in the CSR and use whatever value they are set to use in their configuration. This means that the client will likely need to modify their openssl.conf file to use SHA-256 (or another SHA-2 variant).

4. Using the CSR from the previous step, you can now create the SSL certificate using the CA certificate that was created in [Example — Generate and Import CA certificate with private key pair on OpenSSL](#).

```
openssl x509 -req -days 365 -in fgtssl.csr -CA fgtca.crt -CAkey fgtpcapriv.key -set_serial 01 -out fgtssl.crt
```

This will generate an X.509 certificate good for 365 days signed by the CA certificate fgtca.crt.

Generating a self-signed SSL certificate

This procedure does not require any existing certificates.

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.

```
openssl genrsa -aes256 -out fgtssl.key 2048
openssl req -new -key fgtssl.key -out fgtssl.csr
openssl x509 -req -days 365 -in fgtssl.csr -signkey fgtssl.key -out fgtssl.crt
```

These commands:

- generate an RSA AES256 2048-bit private key,
- generate an SSL certificate signing request, and
- sign the CSR to generate an SSL .CRT certificate file.

Import the SSL certificate into FortiOS

To import the certificate to FortiOS- web-based manager

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.
Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtssl.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtssl.key`.
6. For **Password**, enter the PEM Pass Phrase you entered, such as `fortinet`.
7. Select **OK**.

The SSL certificate you just uploaded can be found under **System > Certificates** under the name of the file you uploaded — `fgtssl`.

To confirm the certificate is uploaded properly - CLI:

```
config vpn certificate local
  edit fgtssl
    get
  end
```

The `get` command will display all the certificate's information. If it is not there or the information is not correct, you will need to remove the corrupted certificate (if it is there) and upload it again from your PC.

To use the new SSL certificate - CLI

```
config vpn ssl settings
  set servercert fgtssl
end
```

This assigns the `fgtssl` certificate as the SSL server certificate. For more information see the FortiOS Handbook SSL VPN guide.

Single sign-on using a FortiAuthenticator unit

If you use a FortiAuthenticator unit in your network as a single sign-on agent,

- Users can authenticate through a web portal on the FortiAuthenticator unit.
- Users with FortiClient Endpoint Security installed can be automatically authenticated by the FortiAuthenticator unit through the FortiClient SSO Mobility Agent.

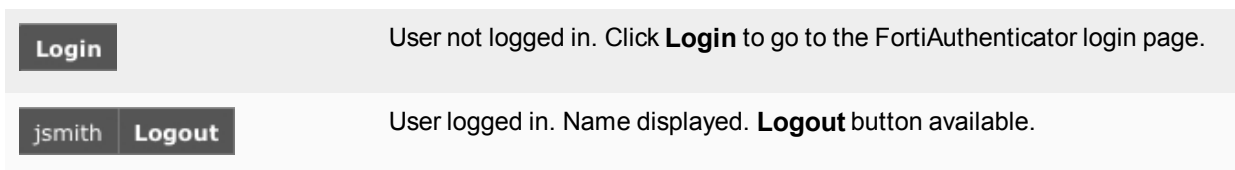

The FortiAuthenticator unit can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit.

User's view of FortiAuthenticator SSO authentication

There are two different ways users can authenticate through a FortiAuthenticator unit.

Users without FortiClient Endpoint Security - SSO widget

To log onto the network, the user accesses the organization's web page with a web browser. Embedded on that page is a simple logon widget, like this:

The SSO widget sets a cookie on the user's browser. When the user browses to a page containing the login widget, the FortiAuthenticator unit recognizes the user and updates its database if the user's IP address has changed. The user will not need to re-authenticate until the login timeout expires, which can be up to 30 days.

Users with FortiClient Endpoint Security - FortiClient SSO Mobility Agent

The user simply accesses resources and all authentication is performed transparently with no request for credentials. IP address changes, such as those due to WiFi roaming, are automatically sent to the FortiAuthenticator unit. When the user logs off or otherwise disconnects from the network, the FortiAuthenticator unit is aware of this and deauthenticates the user.

The FortiClient SSO Mobility Agent, a feature of FortiClient Endpoint Security v5.0, must be configured to communicate with the appropriate FortiAuthenticator unit. After that, the agent automatically provides user name and IP address information to the FortiAuthenticator unit for transparent authentication.

Administrator's view of FortiAuthenticator SSO authentication

You can configure either or both of these authentication types on your network.

SSO widget

You need to configure the Single Sign-On portal on the FortiAuthenticator unit. Go to **Fortinet SSO Methods > SSO > Portal Services** to do this. Copy the **Embeddable login widget** code for use on your organization's

home page. Identity-based security policies on the FortiGate unit determine which users or groups of users can access which network resources.

FortiClient SSO Mobility Agent

Your users must be running at least FortiClient Endpoint Security v5.0 to make use of this type of authentication.

On the FortiAuthenticator unit, you need to select **Enable FortiClient SSO Mobility Agent Service**, optionally select **Enable Authentication** and choose a **Secret key**. Go to **Fortinet SSO Methods > SSO > General**. You need to provide your users the FortiAuthenticator IP address and secret key so that they can configure the FortiClient SSO Mobility Agent on their computers. See [Configuring the FortiGate unit on page 265](#).

Configuring the FortiAuthenticator unit

The FortiAuthenticator unit can poll FortiGate units, Windows Active Directory, RADIUS servers, LDAP servers, and FortiClients for information about user logon activity.

To configure FortiAuthenticator polling:

1. Go to **Fortinet SSO Methods > SSO > General**.
2. In the **FortiGate** section, leave the Listening port at 8000, unless your network requires you to change this. The FortiGate unit must allow traffic on this port to pass through the firewall. Optionally, you can set the Login Expiry time. This is the length of time users can remain logged in before the system logs them off automatically. The default is 480 minutes (8 hours).
3. Select **Enable Authentication** and enter the **Secret key**. Be sure to use the same secret key when configuring the FSSO Agent on FortiGate units.
4. In the **Fortinet Single Sign-On (FSSO)** section, enter

Enable Windows Active Directory domain controllers	Select for integration with Windows Active Directory.
Enable Radius accounting SSO clients	Select if you want to use a Remote Radius server.
Enable Syslog SSO	Select for integration with Syslog server.
Enable FortiClient SSO Mobility Agent service	Select both options to enable single sign-on by clients running FortiClient Endpoint Security. Enter the Secret key . Be sure to use the same secret key in the FortiClient Single Sign-On Mobility Agent settings.
Enable Authentication	

5. Select **OK**.

For more information, see the FortiAuthenticator Administration Guide.

Configuring the FortiGate unit

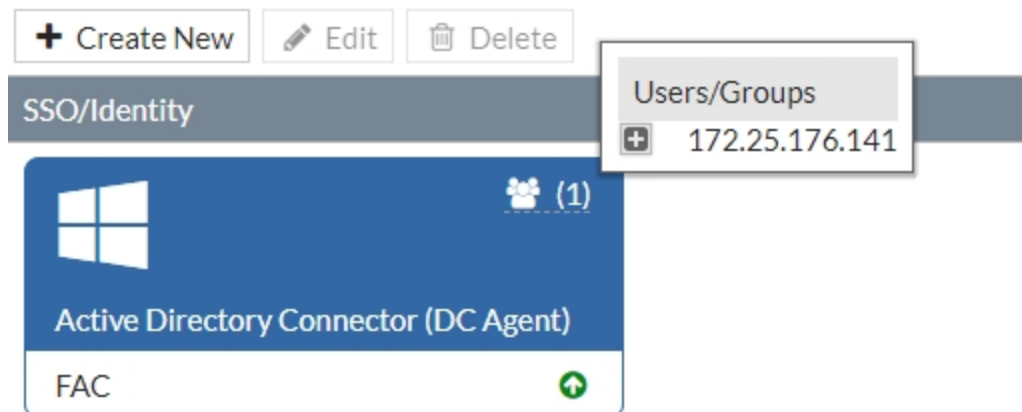

Adding a FortiAuthenticator unit as an SSO agent

On the FortiGate unit, you need to add the FortiAuthenticator unit as a Single Sign-On agent that provides user logon information.

To add a FortiAuthenticator unit as an SSO agent:

1. Go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Under **SSO/Identity**, select **Fortinet Single Sign-On Agent**.
3. Enter a **Name** for the FortiAuthenticator unit (in the example, **FAC**).
4. In **Primary FSSO Agent**, enter the IP address of the FortiAuthenticator unit and password.
On the FortiAuthenticator unit, go to **Fortinet SSO Methods > SSO > General** to define the secret key. Select **Enable Authentication**.
5. Keep **Collector Agent AD access mode** set to **Standard**, and select **OK**.

The entry is shown in the **SSO/Identity** server list, with a green arrow indicating a successful connection. Select the plus-symbol to view the list of user groups that the FortiGate has received from the FortiAuthenticator.

When you open the server, you can see the list of groups. You can use the groups in identity-based security policies.

Configuring an FSSO user group

You cannot use FortiAuthenticator SSO user groups directly in a security policy. Create an FSSO user group and add FortiAuthenticator SSO user groups to it. FortiGate FSSO user groups are available for selection in identity-based security policies.

To create an FSSO user group:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. In Type, select **Fortinet Single Sign-On (FSSO)**.
4. Add **Members**.
The groups available to add as members are SSO groups provided by SSO agents.
5. Select **OK**.

Configuring security policies

You can create identity-based policies based on FSSO groups as you do for local user groups. For more information about security policies see the Firewall chapter.

Configuring the FortiClient SSO Mobility Agent

The user's device must have at least FortiClient Endpoint Security v5.0 installed. Only two pieces of information are required to set up the SSO Mobility Agent feature: the FortiAuthenticator unit IP address and the pre-shared secret.

The user needs to know the FortiAuthenticator IP address and pre-shared secret to set up the SSO Mobility Agent. Or, you could preconfigure FortiClient.

To configure FortiClient SSO Mobility Agent:

1. In FortiClient Endpoint Security, go to **File > Settings**.
You must run the FortiClient application as an administrator to access these settings.
2. Select **Enable single sign-on mobility agent**. Enter the FortiAuthenticator unit IP address, including the listening port number specified on the FortiAuthenticator unit.
Example: 192.168.0.99:8001. You can omit the port number if it is 8005.
3. Enter the pre-shared key.
4. Select **OK**.

Viewing SSO authentication events on the FortiGate unit

User authentication events are logged in the FortiGate event log.

Go to **Log & Report > System Events**.

Single sign-on to Windows AD

The FortiGate unit can authenticate users transparently and allow them network access based on their privileges in Windows AD. This means that users who have logged on to the network are not asked again for their credentials to access network resources through the FortiGate unit, hence the term “Single Sign-On” (SSO).

The following topics are included:

- [Introduction to SSO with Windows AD](#)
- [Configuring SSO to Windows AD](#)
- [FortiOS FSSO log messages](#)
- [Testing FSSO](#)
- [Troubleshooting FSSO](#)

Introduction to SSO with Windows AD

SSO support provided by FortiGate polling of domain controllers is simpler than the earlier method that relies on agent software installed on Windows AD network servers. No Fortinet software needs to be installed on the Windows network. The FortiGate unit needs access only to the Windows AD global catalog and event log.

When a Windows AD user logs on at a workstation in a monitored domain, the FortiGate unit:

- detects the logon event in the domain controller’s event log and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- uses the domain controller’s LDAP server to determine which groups the user belongs to,
- and creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. The selection consists of matching the FSSO group or groups the user belongs to with the security policy or policies that match that group. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

Configuring SSO to Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet SSO, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet SSO (FSSO) sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate unit.

To configure your FortiGate unit to operate with either a Windows AD or a Novell eDirectory FSSO install, you

- Configure LDAP access to the Windows AD global catalog. See [Configuring LDAP server access on page 269](#).
- Configure the LDAP Server as a Single Sign-On server. See [Configuring the LDAP server as an SSO server on page 270](#).
- Add Active Directory user groups to FortiGate FSSO user groups. See [Creating FSSO user groups on page 271](#).
- Create security policies for FSSO-authenticated groups. See [Creating security policies on page 271](#).

- Optionally, specify a guest protection profile to allow guest access. See [Enabling guest access through FSSO security policies on page 272](#)

Configuring LDAP server access

The FortiGate unit needs access to the domain controller's LDAP server to retrieve user group information.

The LDAP configuration on the FortiGate unit not only provides access to the LDAP server, it sets up the retrieval of Windows AD user groups for you to select in FSSO. The LDAP Server configuration, found under **User & Device > LDAP Servers**, includes a function to preview the LDAP server's response to your distinguished name query. If you already know the appropriate Distinguished Name (DN) and User DN settings, you may be able to skip some of the following steps.

To add an LDAP server - web-based manager:

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**. The default common name identifier is **cn**. This is correct for most LDAP servers. However some servers use other identifiers such as **uid**.
4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished Name is **dc=techdoc,dc=local**
5. Select **Fetch DN**, this will fetch the Windows AD directory.

The screenshot shows the 'LDAP Servers' configuration page in the FortiGate web-based manager. The following fields are populated:

- Name:** LDAP
- Server IP/Name:** 10.10.20.3
- Server Port:** 389
- Common Name Identifier:** sAMAccountName
- Distinguished Name:** dc=techdoc,dc=local
- Bind Type:** Regular (selected)
- User DN:** (empty)
- Password:** (empty)
- Secure Connection:** ☐
- Test:** (button)

An expanded window titled 'LDAP Distinguished Name Query' displays an 'LDAP Tree' with the following structure:

- dc=techdoc,dc=local (root)
 - CN=Computers
 - CN=ForeignSecurityPrincipals
 - CN=Managed Service Accounts
 - CN=Program Data
 - CN=System
 - CN=Users
 - OU=Domain Controllers

6. Set **Bind Type** to **Regular**.
7. In the **User DN** field, enter the administrative account name that you created for FSSO. For example, if the account is administrator, enter "administrator@techdoc.local".
8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
 - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
 - In the **Certificate** field, select the appropriate certificate for authentication.

Note that you need to configure the Windows AD for secure connection accordingly.

10. Select **OK**.

11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.

The screenshot shows a configuration window for LDAP. At the top, a blue banner reads "Successful". Below it, the following fields are visible:

- Name:** LDAP
- Server IP/Name:** 10.10.20.3
- Server Port:** 389
- Common Name Identifier:** sAMAccountName
- Distinguished Name:** dc=techdoc,dc=local
- Fetch DN:** A button labeled "Fetch DN".
- Bind Type:** Radio buttons for Simple, Anonymous, and Regular (Regular is selected).
- User DN:** administrator@techdoc.local
- Password:** A masked password field with dots.
- Secure Connection:** An unchecked checkbox.
- Test:** A button labeled "Test".

To configure LDAP for FSSO - CLI example:

```
config user ldap
  edit LDAP
    set server 10.10.20.3
    set cnid sAMAccountName
    set dn dc=techdoc,dc=local
    set type regular
    set username administrator@techdoc.local
    set password <your_password>
  next
end
```

Configuring the LDAP server as an SSO server

The LDAP server must be added to the FortiGate SSO configuration.

To add the LDAP server as an SSO server:

1. Go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Enter the following:

SSO/Identity	Select Poll Active Directory Server .
Server IP/Name	Server Name or IP address of the Domain Controller.
User	A Domain user name.
Password	The user's password.
LDAP Server	Select the LDAP server you added earlier.
Enable Polling	Enable.

3. Select **OK**.

Creating FSSO user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User Groups** and select **Create New**.
The **New User Group** dialog box opens.
2. In the **Name** box, enter a name for the group, `FSSO_Internet_users` for example.
3. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
4. In **Members**, select the required **FSSO** groups.
5. Select **OK**.

To create the `FSSO_Internet-users` user group - CLI

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
      CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

Default FSSO group

`SSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have an FSSO account to authenticate and have access to network resources. See [Enabling guest access through FSSO security policies on page 272](#).

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information.

Incoming Interface	port1
Source Address	company_network
Source User(s)	fsso_group
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
NAT	ON
UTM Security Profiles	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
Log Allowed Traffic	ON. Select Security Events .

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr company_network
    set dstaddr all
    set action accept
    set groups fsso_group
    set schedule always
    set service HTTP HTTPS FTP TELNET
    set nat enable
  end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to Windows AD and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and UTM profiles that apply to guest users — typically guests have access to a reduced set of services. See [Creating security policies on page 271](#).

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see [Enabling security logging on page 216](#). For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events needed, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged.

To enable event logging:

1. Go to **Log & Report > Log Settings**.
2. Under **Log Settings**, set **Event Logging** to **Customize** and select

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

3. Select **Apply**.

List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off

Message ID	Severity	Description
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

Extra filter options for security events

Logon events are detected by the FSSO CA by monitoring the Security Event logs. Additional logon event filters, such as ServiceName and ServiceID, have been implemented so as to avoid instances of conflicting security events, where existing user information could be overwritten.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see [Troubleshooting FSSO on page 274](#).

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command: `diagnose debug authd fssolist`
4. Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 192.168.1.230 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
IP: 192.168.1.240 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
Total number of users logged on: 2
----end of FSSO logons----
```

The exact information will vary based on your installation.

5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fssoserver-status
FGT# Server Name Connection Status
-----
SBS-2003 connected
```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- [General troubleshooting tips for FSSO](#)
- [Users on a particular computer \(IP address\) can not access the network](#)
- [Guest users do not have access to network](#)

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.
FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP).
- Ensure there is at least 64kbps bandwidth between the FortiGate unit and domain controllers. If there is insufficient bandwidth, some FSSO information might not reach the FortiGate unit. The best solution is to configure traffic shaping between the FortiGate unit and the domain controllers to ensure that the minimum bandwidth is always available.

Users on a particular computer (IP address) can not access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediately logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don't have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `SSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

Agent-based FSSO

FortiOS can provide single sign-on capabilities to Windows AD, Citrix, VMware Horizon, Novell eDirectory, or, as of FortiOS 5.4, Microsoft Exchange users with the help of agent software installed on these networks. The agent software sends information about user logons to the FortiGate unit. With user information such as IP address and user group memberships from the network, FortiGate security policies can allow authenticated network access to users who belong to the appropriate user groups without requesting their credentials again.

For Windows AD networks, FortiGate units can provide SSO capability without agent software by directly polling the Windows AD domain controllers. For information about this type of SSO, see [Single sign-on to Windows AD on page 268](#).

The following topics are included:

- [Introduction to agent-based FSSO](#)
- [FSSO NTLM authentication support](#)
- [Agent installation](#)
- [Configuring the FSSO collector agent for Windows AD](#)
- [Configuring the FSSO TS agent for Citrix](#)
- [Configuring FSSO with Novell networks](#)
- [Configuring FSSO advanced settings](#)
- [Configuring FSSO on FortiGate units](#)
- [FortiOS FSSO log messages](#)
- [Testing FSSO](#)
- [Troubleshooting FSSO](#)

Introduction to agent-based FSSO

Fortinet Single Sign-On (FSSO), through agents installed on the network, monitors user logons and passes that information to the FortiGate unit. When a user logs on at a workstation in a monitored domain, FSSO:

- detects the logon event and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- determines which user groups the user belongs to,
- sends the user logon information, including IP address and groups list, to the FortiGate unit,
- and creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

FSSO can also provide NTLM authentication service for requests coming from FortiGate. SSO is very convenient for users, but may not be supported across all platforms. NTLM is not as convenient, but it enjoys wider support. See [FSSO NTLM authentication support on page 282](#).

Introduction to FSSO agents

There are several different FSSO agents that can be used in an FSSO implementation:

- Domain Controller (DC) agent
- eDirectory agent
- Citrix/Terminal Server (TS) agent
- Collector agent

Consult the latest FortiOS and FSSO Release Notes for operating system compatibility information.

Domain Controller (DC) agent

The Domain Controller (DC) agent must be installed on every domain controller if you will use DC Agent mode, but is not required if you use Polling mode. See [FSSO for Windows AD on page 278](#).

eDirectory agent

The eDirectory agent is installed on a Novell network to monitor user logons and send the required information to the FortiGate unit. It functions much like the Collector agent on a Windows AD domain controller. The agent can obtain information from the Novell eDirectory using either the Novell API or LDAP.

Terminal Server (TS) agent

Terminal Server (TS) agent can be installed on a Citrix or VMware Horizon 7.4 terminal server to monitor user logons in real time. It functions much like the DC Agent on a Windows AD domain controller.

Collector agent

This agent is installed as a service on a server in the Windows AD network to monitor user logons and send the required information to the FortiGate unit. The Collector agent can collect information from

- Domain Controller agent (Windows AD)
- TS agent (Citrix or VMware Horizon Terminal Server)

In a Windows AD network, the Collector agent can optionally obtain logon information by polling the AD domain controllers. In this case, DC agents are not needed.

The Collector can obtain user group information from the DC agent or optionally, a FortiGate unit can obtain group information directly from AD using Lightweight Directory Access Protocol (LDAP).

On a Windows AD network, the FSSO software can also serve NT LAN Manager (NTLM) requests coming from client browsers (forwarded by the FortiGate unit) with only one or more Collector agents installed. See [FSSO NTLM authentication support on page 282](#).

The CA is responsible for DNS lookups, group verification, workstation checks, and as mentioned FortiGate updates of logon records. The FSSO Collector Agent sends Domain Local Security Group and Global Security Group information to FortiGate units. The CA communicates with the FortiGate over TCP port 8000 and it listens on UDP port 8002 for updates from the DC agents.

The FortiGate unit can have up to five CAs configured for redundancy. If the first on the list is unreachable, the next is attempted, and so on down the list until one is contacted. See [Configuring FSSO on FortiGate units on page 310](#).

All DC agents must point to the correct Collector agent port number and IP address on domains with multiple DCs.

A FortiAuthenticator unit can act much like a Collector agent, collecting Windows AD user logon information and sending it to the FortiGate unit. It is particularly useful in large installations with several FortiGate units. For more information, see the [FortiAuthenticator Administration Guide](#).

FSSO for Microsoft Exchange Server

As of FortiOS 5.4, FSSO supports monitoring Microsoft Exchange Server. This is useful for situations when the user accesses the domain account to view their email, even when the client device might not be in the domain.

Support for the Exchange server is configured on the Back-end FSSO collector agent. For more information on the collector agent, see [Collector agent installation](#):

1. On the FSSO collector agent, go to **Advanced Settings > Exchange Server**.
2. Select **Add** and enter the following information and select **OK**:

Domain Name	Enter your domain name.
Server IP/Hostname	Enter the IP address or the hostname of your exchange server.
Polling forwarded event log	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
Ignore Name	<p>Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ESEventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to.</p> <p>To do so, enter the domain name in the Ignore Name field and select Add.</p>

FSSO for Windows AD

FSSO for Windows AD requires at least one Collector agent. Domain Controller agents may also be required depending on the Collector agent working mode. There are two working modes to monitor user logon activity: DC Agent mode or Polling mode.

Collector agent DC Agent mode versus Polling mode

	DC Agent mode	Polling Mode
Installation	Complex — Multiple installations: one agent per DC plus Collector agent, requires a reboot	Easy — Only Collector agent installation, no reboot required

	DC Agent mode	Polling Mode
Resources	Shares resources with DC system	Has own resources
Network load	Each DC agent requires minimum 64kpbs bandwidth, adding to network load	Increase polling period during busy period to reduce network load
Level of Confidence	Captures all logons	Potential to miss a login if polling period is too great

DC Agent mode

DC Agent mode is the standard mode for FSSO. In DC Agent mode, a Fortinet authentication agent is installed on each domain controller. These DC agents monitor user logon events and pass the information to the Collector agent, which stores the information and sends it to the FortiGate unit.

The DC agent installed on the domain controllers is not a service like the Collector agent — it is a DLL file called `dcagent.dll` and is installed in the `Windows\system32` directory. It must be installed on all domain controllers of the domains that are being monitored.

FSSO in DC agent mode

DC Agent mode provides reliable user logon information, however you must install a DC agent on every domain controller. A reboot is needed after the agent is installed. Each installation requires some maintenance as well. For these reasons it may not be possible to use the DC Agent mode.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. You can optionally configure traffic shapers on the FortiGate unit to ensure this minimum bandwidth is guaranteed for the domain controller connections.

Polling mode

In Polling mode there are three options — NetAPI polling, Event log polling, and Event log using WMI. All share the advantages of being transparent and agentless.

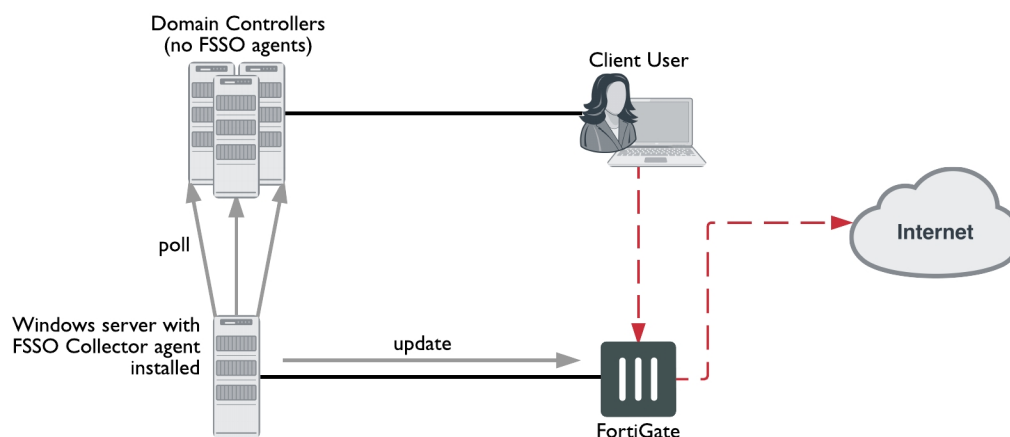

NetAPI polling is used to retrieve server logon sessions. This includes the logon event information for the Controller agent. NetAPI runs faster than Event log polling but it may miss some user logon events under heavy system load. It requires a query round trip time of less than 10 seconds.

Event log polling may run a bit slower, but will not miss events, even when the installation site has many users that require authentication. It does not have the 10 second limit on NetAPI polling. Event log polling requires fast network links. Event log polling is required if there are Mac OS users logging into Windows AD.

Event log using WMI polling: WMI is a Windows API to get system information from a Windows server, CA is a WMI client and sends WMI queries for user logon events to DC, which in this case is a WMI server. Main advantage in this mode is that CA does not need to search security event logs on DC for user logon events, instead, DC returns all requested logon events via WMI. This also reduces network load between CA and DC.

In Polling mode, the Collector agent polls port 445 of each domain controller for user logon information every few seconds and forwards it to the FortiGate unit. There are no DC Agents installed, so the Collector agent polls the domain controllers directly.

FSSO in polling mode

A major benefit of Polling mode is that no FSSO DC Agents are required. If it is not possible to install FSSO DC Agents on your domain controllers, this is the alternate configuration available to you. Polling mode results in a less complex install, and reduces ongoing maintenance. The minimum permissions required in Polling mode are to read the event log or call NetAPI.

Collector agent AD access mode - standard versus advanced

The Collector agent has two ways to access Active Directory user information. The main difference between standard and advanced mode is the naming convention used when referring to username information.

Standard mode uses regular Windows convention: Domain\Username. Advanced mode uses LDAP convention: CN=User, OU=Name, DC=Domain.

If there is no special requirement to use LDAP— best practices suggest you set up FSSO in standard mode. This mode is easier to set up, and is usually easier to maintain and troubleshoot.

Standard and advanced modes have the same level of functionality with the following exceptions:

- Users have to create Group filters on the Collector agent. This differs from advanced mode where Group filters are configured from the FortiGate unit. Fortinet strongly encourages users to create filters from CA.
- Advanced mode supports nested or inherited groups. This means that users may be a member of multiple monitored groups. Standard mode does not support nested groups so a user must be a direct member of the group being monitored.

FSSO for Citrix

Citrix users can enjoy a similar Single Sign-On experience as Windows AD users. The FSSO TS agent installed on each Citrix server provides user logon information to the FSSO Collector agent on the network. The FortiGate unit uses this information to authenticate the user in security policies.

Citrix SSO topology

Citrix users do not have unique IP addresses. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

FSSO for Novell eDirectory

FSSO in a Novell eDirectory environment works similar to the FSSO Polling mode in the Windows AD environment. The eDirectory agent polls the eDirectory servers for user logon information and forwards the information to the FortiGate unit. There is no need for the Collector agent.

When a user logs on at a workstation, FSSO:

- detects the logon event by polling the eDirectory server and records the IP address and user ID,
- looks up in the eDirectory which groups this user belongs to,
- sends the IP address and user groups information to the FortiGate unit.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

FSSO is supported on the Novell E-Directory 8.8 operating system.

For a Novell network, there is only one FSSO component to install — the eDirectory agent. In some cases, you also need to install the Novell Client.

FSSO security issues

When the different components of FSSO are communicating there are some inherent security features.

FSSO installation requires an account with network admin privileges. The security inherent in these types of accounts helps ensure access to FSSO configurations is not tampered with.

User passwords are never sent between FSSO components. The information that is sent is information to identify a user including the username, group or groups, and IP address.

NTLM uses base-64 encoded packets, and uses a unique randomly generated challenge nonce to avoid sending user information and password between the client and the server.

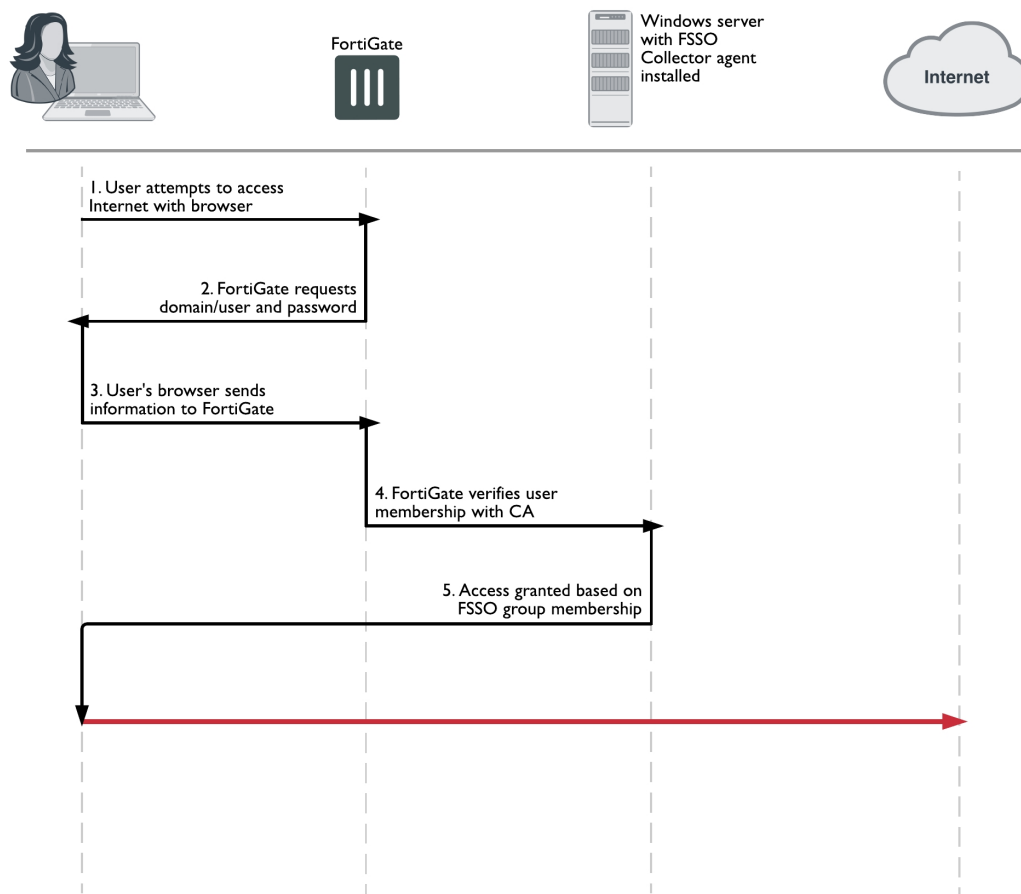

FSSO NTLM authentication support

In a Windows AD network, FSSO can also provide NTLM authentication service to the FortiGate unit. When the user makes a request that requires authentication, the FortiGate unit initiates NTLM negotiation with the client browser. The FortiGate unit does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service to process.

NTLM has the benefit of not requiring an FSSO agent, but it is not transparent to users, and the user's web browser must support NTLM.

The NTLM protocol protects the user's password by not sending it over the network. Instead, the server sends the client a random number that the client must encrypt with the hash value of the user's password. The server compares the result of the client's encryption with the result of its own encryption. The two will match only if both parties used the same password.

NTLM authentication

If the NTLM authentication with the Windows AD network is successful, and the user belongs to one of the groups permitted in the applicable security policy, the FortiGate unit allows the connection but will require authentication again in the future when the current authentication expires.

Fortinet has tested NTLM authentication with Internet Explorer and Firefox browsers.

NTLM in a multiple domain environment

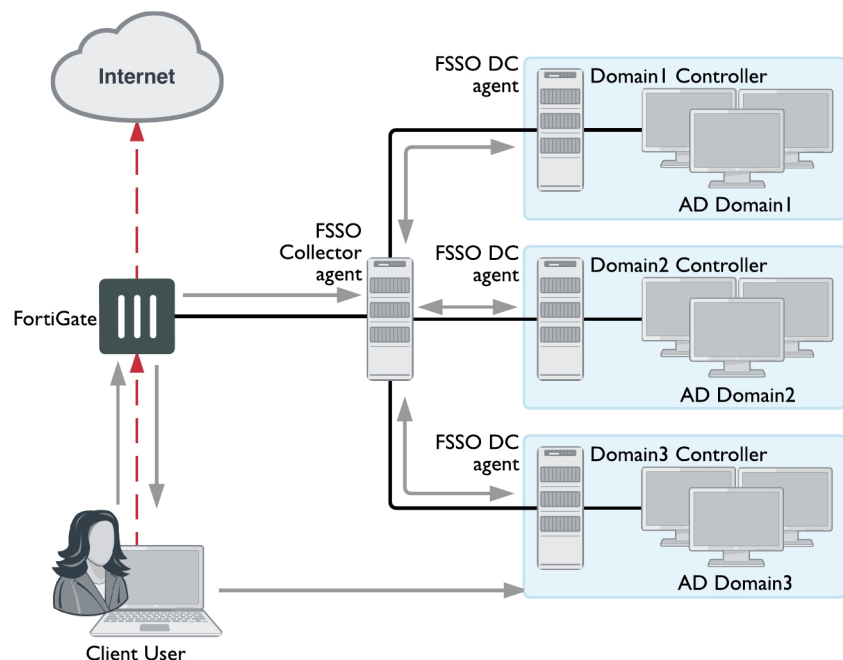

In a multiple domain environment for NTLM, the important factor is that there is a trust relation between the domains. In a forest, this relation is automatically created. So you can install FSSO agent on one of the domain controllers without worry.

But in case of multiple domains that are not in a forest, you need to create a trust relation between the domains. If you do not want to have a trust relation between your multiple domains, you need to use FSAE 4.0 MR1 and the DC agent needs to be installed once on each domain. Then you can use security policies to configure server access.

In the figure below, three domains are shown connected to the FSSO Collector agent server. The Client logs on to their local Domain Controller, which then sends the user logon event information to the Collector Agent. When the Client attempts to access the Internet, the FortiGate unit contacts the Collector Agent for the logon information, sees the Client is authenticated, and allows access to the Internet. There are multiple domains each

with a domain controller agent (DCagent) that sends logon information to the Collector agent. If the multiple domains have a trust relationship, only one DCagent is required instead of one per domain.

FSSO NTLM with multiple domains not in a forest

Understanding the NTLM authentication process

1. The user attempts to connect to an external (internet) HTTP resource. The client application (browser) on the user's computer issues an unauthenticated request through the FortiGate unit.
2. The FortiGate is aware that this client has not authenticated previously, so responds with a 401 Unauthenticated status code, and tells the client which authentication method to reply with in the header: Proxy-Authenticated: NTLM. Then the initial session is dismantled.
3. The client application connects again to the FortiGate, and issues a GET-request, with a Proxy-Authorization: NTLM <negotiate string> header. <negotiate-string> is a base64-encoded NTLM Type 1 negotiation packet.
4. The FortiGate unit replies with a 401 "proxy auth required" status code, and a Proxy-Authenticate: NTLM <challenge string> (a base 64-encoded NTLM Type 2 challenge packet). In this packet is the challenge nonce, a random number chosen for this negotiation that is used once and prevents replay attacks.

The TCP connection must be kept alive, as all subsequent authentication-related information is tied to the TCP connection. If it is dropped, the authentication process must start again from the beginning.

5. The client sends a new GET-request with a header: Proxy-Authenticate: NTLM <authenticate string>, where <authenticate string> is a NTLM Type 3 Authentication packet that contains:

- username and domain
 - the challenge nonce encoded with the client password (it may contain the challenge nonce twice using different algorithms).
6. If the negotiation is successful and the user belongs to one of the groups permitted in the security policy, the connection is allowed. Otherwise, the FortiGate unit denies the authentication by issuing a 401 return code and prompts for a username and password. Unless the TCP connection is broken, no further credentials are sent from the client to the proxy.

If the authentication policy reaches the authentication timeout period, a new NTLM handshake occurs.

Agentless NTLM support

Agentless NTLM authentication can be configured directly from the FortiGate to the Domain Controller via SMB protocol (no agent is required).

Note that this authentication method is only supported for proxy policies.

Syntax

Note that `domain-controller` is only available when `method` is set to `ntlm` and/or `negotiate-ntlm` is set to `enable`.

```
config authentication scheme
  edit <name>
    set method ntlm
    set domain-controller <dc-setting>
  next
end

config user domain-controller
  edit <name>
    set ip-address <dc-ip>
    set port <port> - default = 445
    set domain-name <dns-name>
    set ldap-server <name>
  next
end
```

Agent installation

After reading the appropriate sections of [Introduction to agent-based FSSO on page 276](#) to determine which FSSO agents you need, you can proceed to perform the necessary installations.

Ensure you have administrative rights on the servers where you are installing FSSO agents. It is best practice to install FSSO agents using the built-in local administrator account. Optionally, you can install FSSO without an admin account. See [Installing FSSO without using an administrator account on page 288](#).

In Windows 2008 by default, you do not have administrative user rights if you are logged on as a user other than as the built-in administrator, even if you were added to the local Administrators group on the computer.

The FSSO installer first installs the Collector agent. You can then continue with installation of the DC agent, or you can install it later by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**. The installer will install a DC agent on the domain controllers of all of the trusted domains in your network.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. Traffic shapers configured on the FortiGate can help guarantee these minimum bandwidths.

Collector agent installation

To install FSSO, you must obtain the FSSO_Setup file from the [Fortinet Support web site](#). This is available as either an executable (.exe) or a Microsoft Installer (.msi) file. Then you follow these two installation procedures on the server that will run the Collector agent. This can be any server or domain controller that is part of your network. These procedures also install the DC Agent on all of the domain controllers in your network.

IPv6 source addresses can be configured for connecting to an FSSO agent.

To install the Collector agent:

1. Create an account with administrator privileges and a password that does not expire. See Microsoft Advanced Server documentation for help with this task.
To use a non-admin read only account, see [Installing FSSO without using an administrator account on page 288](#).
2. Log on to the account that you created in Step 1.
3. Double-click the `FSSOSetup.exe` file.
The Fortinet SSO Collector Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Optionally, change the **User Name**.
8. By default, the agent is installed using the currently running account. If you want FSSO to use another existing admin account, change the **User Name** using the format `DomainName \ UserName`. For example if the account is `jsmith` and the domain is **example_corp** you would enter `example_corp\jsmith`.
9. In the **Password** field, enter the password for the account listed in the **User Name** field.
10. Select **Next**.
11. Enable as needed:
 - Monitor user logon events and send the information to the FortiGate unit
 - Serve NTLM authentication requests coming from FortiGateBy default, both methods are enabled. You can change these options after installation.
12. Select the access method to use for Windows Directory:
13. Select **Standard** to use Windows domain and username credentials.
14. Select **Advanced** if you will set up LDAP access to Windows Directory.
See [Collector agent AD access mode - standard versus advanced on page 280](#).

15. Select **Next** and then select **Install**.

If you want to use DC Agent mode, ensure that **Launch DC Agent Install Wizard** is selected. This will start DC agent installation immediately after you select **Finish**.

16. Select **Finish**.

If you see an error such as Service Fortinet Single Sign On agent (service_FSAE) failed to start, there are two possible reasons for this. Verify the user account you selected has sufficient privileges to run the FSSO service. Also verify the computer system you are attempting to install on is a supported operating system and version.

DC agent installation

The FSSO_Setup file contains both the Collector agent and DC Agent installers, but the DC Agent installer is also available separately as either a .exe or .msi file named DCAgent_Setup.

To install the DC Agent

1. If you have just installed the Collector agent, the FSSO - Install DC Agent wizard starts automatically. Otherwise, go to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
2. Select **Next**.
3. Read and accept the license agreement. Select **Next**.
4. Optionally, you can change the installation location. Select **Next**.
5. Enter the **Collector agent IP address**.
6. If the Collector agent computer has multiple network interfaces, ensure that the one that is listed is on your network. The listed **Collector agent listening port** is the default. Only change this if the port is already used by another service.
7. Select **Next**.
8. Select the domains to monitor and select **Next**.
9. If any of your required domains are not listed, cancel the wizard and set up the proper trusted relationship with the domain controller. Then run the wizard again by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
10. Optionally, select users that you do not want monitored. These users will not be able to authenticate to FortiGate units using FSSO. You can also do this later. See [Configuring the FSSO collector agent for Windows AD on page 290](#).
11. Select **Next**.
12. Optionally, clear the check boxes of domain controllers on which you do not want to install the DC Agent.
13. Select the **Working Mode** as DC Agent Mode. While you can select Polling Mode here, in that situation you would not be installing a DC Agent. For more information, see [DC Agent mode on page 279](#) and [Polling mode on page 279](#).
14. Select **Next**.
15. Select **Yes** when the wizard requests that you reboot the computer.

If you reinstall the FSSO software on this computer, your FSSO configuration is replaced with default settings.

If you want to create a redundant configuration, repeat the Collector agent installation procedure on at least one other Windows AD server.

When you start to install a second Collector agent, cancel the Install Wizard dialog appears the second time. From the configuration GUI, the monitored domain controller list will show your domain controllers un-selected. Select the ones you wish to monitor with this Collector agent, and select **Apply**.

Before you can use FSSO, you need to configure it on both Windows AD and on the FortiGate units. [Configuring FSSO on FortiGate units on page 310](#) will help you accomplish these two tasks.

Installing FSSO without using an administrator account

Normally when installing services in Windows, it is best to use the Domain Admin account, as stated earlier. This ensures installation goes smoothly and uninterrupted, and when using the FSSO agent there will be no permissions issues. However, it is possible to install FSSO with a non-admin account in Windows 2003 or 2008 AD.

The following instructions for Windows 2003 are specific to the event log polling mode only. Do not use this procedure with other FSSO configurations.

Windows 2003

There are two methods in Windows 2003 AD for installing FSSO without an admin account — add the non-admin user to the security log list, and use a non-admin account with read-only permissions. A problem with the first method is that full rights (read, write, and clear) are provided to the event log. This can be a problem when audits require limited or no write access to logs. In those situations, the non-admin account with read-only permissions is the solution.

To add the non-admin user account to the Windows 2003 security log list :

1. Go to **Default Domain Controller Security Settings > Security Settings > User Rights Assignment > Manage auditing and security log**.
2. Add the user account to this list.
3. Repeat these steps on every domain controller in Windows 2003 AD.
A reboot is required.

To use a non-admin account with read-only permissions to install FSSO on Windows 2003:

The following procedure provides the user account specified with read only access to the Windows 2003 AD Domain Controller Security Event Log which allows FSSO to function.

1. Find out the SID of the account you intend to use.
Tools for this can be downloaded for free from <http://technet.microsoft.com/en-us/sysinternals/bb897417>.
2. Then create the permission string. For example:
 - (A;;0x1;;;S-1-5-21-4136056096-764329382-1249792191-1107)
 - A means Allow,

- 0x1 means Read, and
 - S-1-5-21-4136056096-764329382-1249792191-1107 is the SID.
3. Then, append it to the registry key:
HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Eventlog\Security\CustomSD
 4. Repeat these steps on every domain controller in Windows 2003 AD.
A reboot is required.

Windows 2008

In Windows 2008 AD, if you do not want to use the Domain Admin account then the user account that starts the FSSO agent needs to be added to the Event Log Readers group.

When the user is added to the Event Log Readers group, that user is now allowed to have read only access to the event log and this is the minimal rights required for FSSO to work.

Citrix TS agent installation

To install the Citrix TS agent, you must obtain the TSAgent_Setup file from the [Fortinet Support web site](#). Perform the following installation procedure on the Citrix server.

To install the FSSO TS agent:

1. On the Citrix server, create an account with administrator privileges and a password that does not expire. See Citrix documentation for more information.
2. Log on to the account that you created in step 1.
3. Double-click the TSAgent_Setup installation file.
The Fortinet SSO Terminal Server Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Verify that **This Host IP Address** is correct.
8. In the **FSSO Collector Agent List**, enter the IP address(es) of your Collector Agents.
9. Select **Next** and then select **Install**.
The TS agent is installed.
10. Select **Finish**.

Novell eDirectory agent installation

To install the eDirectory agent, you must obtain the FSSO_Setup_eDirectory file from the [Fortinet Support web site](#). Perform the following installation procedure on the computer that will run the eDirectory agent. This can be any server or domain controller that is part of your network. You will need to provide some setup information.

To install the FSSO eDirectory agent:

1. Create an account with administrator privileges and a password that does not expire. See Novell documentation for more information.
2. Log on to the account that you created in step 1.
3. Double-click the FSSO_Setup_edirectory file to start the installation wizard.
4. Select **Next**.

5. Read and accept the license agreement. Select **Next**.
6. Optionally, change the installation location. Select **Next**.
7. Enter:

eDirectory Server	
Server Address	Enter the IP address of the eDirectory server.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.

8. Select **Next**.
9. Select **Install**. When the installation completes, select **Finish**.

Updating FSSO agents on Windows AD

After FSSO is installed on your network, you may want to upgrade to a newer version. The following procedure helps ensure you have a trouble free upgrade. How you update FSSO depends on if you are using polling mode or DC Agent mode.

For polling mode, since there are no DC agents you only need to upgrade the Collector. However in DC Agent mode, each DC Agent must be updated as well.

To update FSSO in DC Agent mode:

1. Go to the system32 directory on all DC's and rename the `dcagent.dll` file to `dcagent.dll.old`. This ensures the when the upgrade is pushed to the DC it does not overwrite the old file. If there are any problems this makes it easy to revert to the old version.
2. Run the FSSO setup .exe file to update the collector. When this is completed, ignore any reboot message.
3. Go to **Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent** and push the DC agent out to all servers. All DC's will now need to be rebooted so that the new DLL file is loaded.
4. After the reboot, go to all DC's and delete the `dcagent.dll.old` files.

Configuring the FSSO collector agent for Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units.

To avoid this problem, you can configure the Fortinet Single Sign On Collector agent to send logon information only for groups named in the FortiGate unit's security policies. See [Configuring FortiGate group filters on page 297](#).

On each server with a Collector agent, you will be

- [Configuring Windows AD server user groups](#)
- [Configuring collector agent settings](#), including the domain controllers to be monitored
- [Selecting Domain Controllers and working mode for monitoring](#)
- [Configuring directory access settings](#)
- [Configuring the ignore user list](#)
- [Configuring FortiGate group filters for each FortiGate unit](#)
- [Configuring FSSO ports](#)
- [Configuring alternate user IP address tracking](#)
- [Viewing FSSO component status](#)

Configuring Windows AD server user groups

FortiGate units control network resource access at the group level. All members of a user group have the same network access as defined in FortiGate security policies.

You can use existing Windows AD user groups for authentication to FortiGate units if you intend that all members within each group have the same network access privileges.

Otherwise, you need to create new user groups for this purpose.

If you change a user's group membership, the change does not take effect until the user logs off and then logs on again.

The FSSO Agent sends only Domain Local Security Group and Global Security Group information to FortiGate units. You cannot use Distribution group types for FortiGate access. No information is sent for empty groups.

Refer to Microsoft documentation for information about creating and managing Windows AD user groups.

Configuring collector agent settings

You need to configure which domain controllers the Collector agent will use and which domains to monitor for user logons. You can also alter default settings and settings you made during installation. These tasks are accomplished by configuring the FSSO Collector Agent, and selecting either Apply to enable the changes.

At any time to refresh the FSSO Agent settings, select Apply.

To configure the collector agent:

1. From the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**.
2. Enter the following information.

Monitoring user logon events	By default, this is enabled to automatically authenticate users as they log on to the Windows domain. Disable the Monitor feature only if you have a large network where this feature will slow responses too much.
Support NTLM authentication	By default, this is enabled to facilitate logon of users who are connected to a domain that does not have the FSSO DC Agent installed. Disable NTLM authentication only if your network does not support NTLM authentication for security or other reasons.
Collector Agent Status	Shows RUNNING when Collector agent is active.
Listening ports	You can change FSSO Collector Agent related port numbers if necessary.
FortiGate	TCP port for FortiGate units. Default 8000.
DC Agent	UDP port for DC Agents. Default 8002.
Logging	
Log level	Select the minimum severity level of logged messages.

Log file size limit (MB)	Enter the maximum size for the log file in MB. Default is 10.
View Log	View all Fortinet Single Sign On agent logs.
Log logon events in separate logs	<p>Record user login-related information separately from other logs. The information in this log includes:</p> <ul style="list-style-type: none"> • data received from DC agents • user logon/logoff information • workstation IP change information • data sent to FortiGate units
View Logon Events	If Log logon events in separate logs is enabled, you can view user login-related information.
Authentication	
Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the Collector agent.
Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 15 characters. The default password is "fortinetcanada". It is highly recommended to modify this password.
Timers	
Workstation verify interval (minutes)	<p>Enter the interval in minutes at which the Fortinet Single Sign On Collector agent connects to client computers to determine whether the user is still logged on. The default is every 5 minutes. The interval may be increased if your network has too much traffic.</p> <p>Note: This verification process creates security log entries on the client computer.</p> <p>If ports 139 or 445 cannot be opened on your network, set the interval to 0 to prevent checking. See Configuring FSSO ports on page 299.</p>
Dead entry timeout interval	<p>Enter the interval in minutes after which Fortinet Single Sign On Agent purges information for user logons that it cannot verify. The default is 480 minutes (8 hours).</p> <p>Dead entries usually occur because the computer is unreachable (such as in standby mode or disconnected) but the user has not logged off. A common reason for this is when users forget to logoff before leaving the office for the day.</p> <p>You can also prevent dead entry checking by setting the interval to 0.</p>

IP address change verify interval	<p>Fortinet Single Sign On Agent periodically checks the IP addresses of logged-in users and updates the FortiGate unit when user IP addresses change. IP address verification prevents users from being locked out if they change IP addresses, as may happen with DHCP assigned addresses.</p> <p>Enter the verification interval in seconds. The default is 60 seconds. You can enter 0 to prevent IP address checking if you use static IP addresses.</p> <p>This does not apply to users authenticated through NTLM.</p>
Cache user group lookup result	<p>Enable caching.</p> <p>Caching can reduce group lookups and increase performance.</p>
Cache expire in (minutes)	<p>Fortinet Single Sign On Agent caches group information for logged-in users.</p> <p>Enter the duration in minutes after which the cache entry expires. If you enter 0, the cache never expires.</p> <p>A long cache expire interval may result in more stale user group information. This can be an issue when a user's group information is changed.</p>
Clear Group Cache	<p>Clear group information of logged-in users.</p> <p>This affects all logged-in users, and may force them to re-login.</p>

3. You can select **Save & close** now or leave the agent configuration window open to complete additional configuration in the following sections.

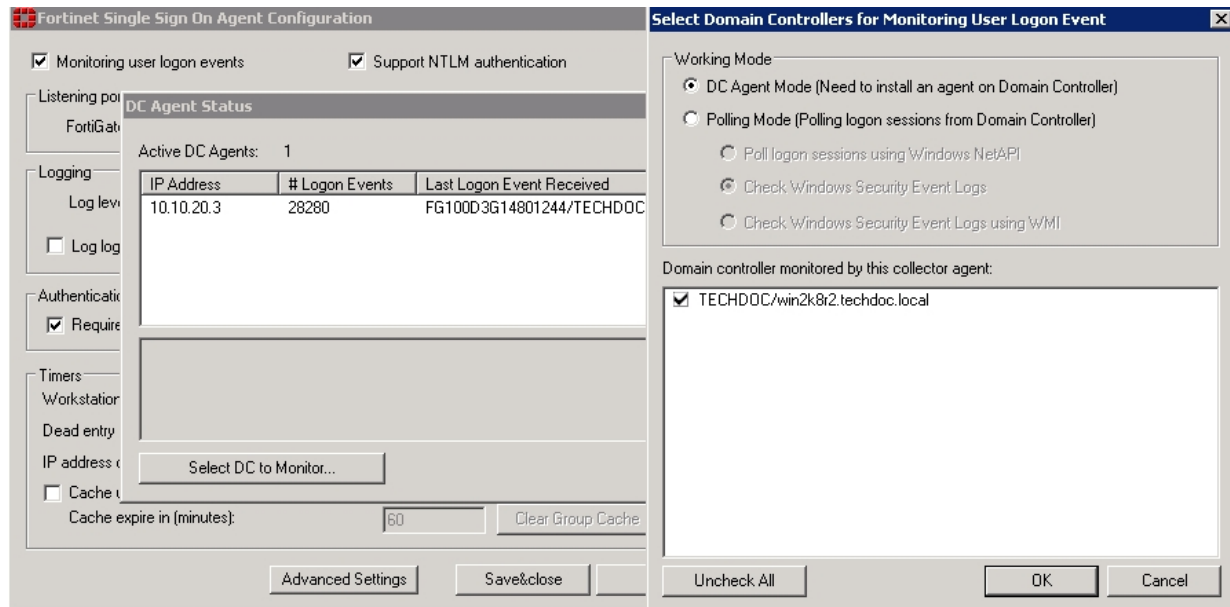

To view the version and build number information for your FSSO Collector Agent configuration, selecting the Fortinet icon in the upper left corner of the Collector agent Configuration screen and select **About Fortinet Single Sign On Agent configuration**.

Selecting Domain Controllers and working mode for monitoring

You can change which DC agents are monitored or change the working mode for logon event monitoring between DC agent mode and polling mode.

When polling mode is selected, it will poll port 445 of the domain controller every few seconds to see who is logged on.

1. From the Start menu select **Programs > Fortinet Fortinet Single Sign-On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.
3. Select **Select DC to Monitor**.

4. Choose the **Working Mode**:

- **DC Agent mode** — a Domain Controller agent monitors user logon events and passes the information to the Collector agent. This provides reliable user logon information, however you must install a DC agent on every domain controller in the domain.
- **Polling mode** — the Collector agent polls each domain controller for user logon information. Under heavy system load this might provide information less reliably. However installing a DC agent on each domain controller is not required in this mode.

5. You also need to choose the method used to retrieve logon information:

- Poll logon sessions using Windows NetAPI
- Check Windows Security Event Logs
- Check Windows Security Event Logs using WMI

For more information about these options, see [Polling mode on page 279](#).

6. Select **OK**.

7. Select **Close**.

8. Select **Save & Close**.

Configuring directory access settings

The FSSO Collector Agent can access Windows Active Directory in one of two modes:

- **Standard** — the FSSO Collector Agent receives group information from the Collector agent in the **domain\user** format. This option is available on FortiOS 3.0 and later.
- **Advanced** — the FSSO Collector Agent obtains user group information using LDAP. The benefit of this method is that it is possible to nest groups within groups. This option is available on FortiOS 3.0 MR6 and later. The group information is in standard LDAP format.

If you change AD access mode, you must reconfigure your group filters to ensure that the group information is in the correct format.

To configure Directory Access settings:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Directory Access Information**.
The **Set Directory Access Information** dialog box opens.
3. From the **AD access mode** list, select either **Standard** or **Advanced**.
4. If you selected Advanced AD access mode, select **Advanced Setting** and configure the following settings and then select **OK**:

AD server address	Enter the address of your network's global catalog server.
AD server port	The default AD server port is 3268. This must match your server port.
BaseDN	Enter the Base distinguished name for the global catalog. This is the point in the tree that will be considered the starting point by default-See following example.
Username	If the global catalog accepts your Fortinet Single Sign On Agent agent's credentials, you can leave these fields blank. Otherwise, enter credentials for an account that can access the global catalog.
Password	

BaseDN example

An example DN for Training Fortinet Canada is `ou=training, ou=canada, dc=fortinet, dc=com`. If you set the **BaseDN** to `ou=canada, dc=fortinet, dc=com` then when Fortinet Single Sign On Agent is looking up user credentials, it will only search the Canada organizational unit, instead of all the possible countries in the company. Its a short cut to entering less information and faster searches.

However, you may have problems if you narrow the BaseDN too much when you have international employees from the company visiting different offices. If someone from Fortinet Japan is visiting the Canada office in the example above, their account credentials will not be matched because they are in `ou=japan, dc=fortinet, dc=com` instead of the BaseDN `ou=canada, dc=fortinet, dc=com`. The easy solution is to change the BaseDN to simply be `dc=fortinet, dc=com`. Then any search will check all the users in the company.

Configuring the ignore user list

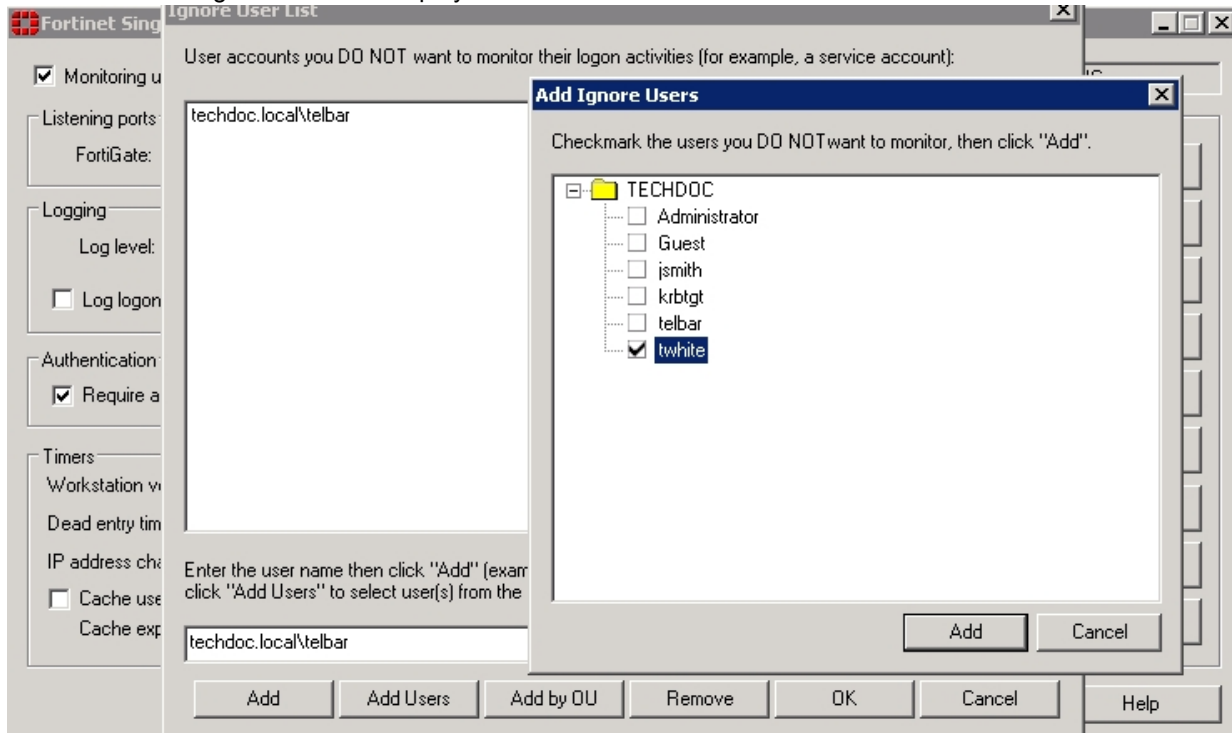

The ignore user list excludes users that do not authenticate to any FortiGate unit, such as system accounts. The logons of these users are not reported to FortiGate units. This reduces the amount of required resources on the FortiGate unit especially when logging logon events to memory.

To configure the ignore user list:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.

2. In the **Common Tasks** section, select **Set ignore user list**.

The current list of ignored users is displayed:

3. Do any of the following:

- To remove a user from the list, select the the username and then select **Remove**. The user's login is no longer ignored.
- To add users to be ignored,
 - enter the username in the format **domain\username** and select **Add** or
 - select **Add Users**, an **Add Ignore Users** window is displayed, checkmark the users you do not want to monitor, then select **Add** or
 - select **Add by OU**, an **Add Ignore Users by OU** window is displayed, select an OU from the directory tree, then select **Add**. All users under the selected OU will be added to the ignore user list.

4. Select **OK**.

Configuring FortiGate group filters

FortiGate group filters actively control which user logon information is sent to each FortiGate unit. You need to configure the group filter list so that each FortiGate unit receives the correct user logon information for the user groups that are named in its security policies. These group filters help limit the traffic sent to the FortiGate unit, and help limit the logon events logged.

The maximum number of Windows AD user groups allowed on a FortiGate depends on the model. Low end models support 256 Windows AD user groups, where mid and high end models support 1024 groups. This is per VDOM if VDOMs are enabled on the FortiGate unit.

You do not need to configure a group filter on the Collector agent if the FortiGate unit retrieves group information from Windows AD using LDAP. In that case, the Collector agent uses the list of groups you selected on the FortiGate unit as its group filter.

The filter list is initially empty. You need to configure filters for your FortiGate units using the Add function. At a minimum, create a default filter that applies to all FortiGate units without a defined filter.

If no filter is defined for a FortiGate unit and there is no default filter, the Collector agent sends all Windows AD group and user logon events to the FortiGate unit. While this normally is not a problem, limiting the amount of data sent to the FortiGate unit improves performance by reducing the amount of memory the unit uses to store the group list and resulting logs.

To configure a FortiGate group filter:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Group Filters**.
The FortiGate Filter List opens. It has the following columns:

FortiGate SN	The serial number of the FortiGate unit to which this filter applies.
Description	An optional description of the role of this FortiGate unit.
Monitored Groups	The Windows AD user groups that are relevant to the security policies on this FortiGate unit.
Add	Create a new filter.
Edit	Modify the filter selected in the list.
Remove	Remove the filter selected in the list.
OK	Save the filter list and exit.
Cancel	Cancel changes and exit.

3. Select **Add** to create a new filter. If you want to modify an existing filter, select it in the list and then select **Edit**.
4. Enter the following information and then select **OK**.

Default filter	Select to create the default filter. The default filter applies to any FortiGate unit that does not have a specific filter defined in the list.
FortiGate Serial Number	Enter the serial number of the FortiGate unit to which this filter applies. This field is not available if Default is selected.
Description	Enter a description of this FortiGate unit's role in your network. For example, you could list the resources accessed through this unit. This field is not available if Default is selected.
Monitor the following groups	The Collector agent sends to the FortiGate unit the user logon information for the Windows AD user groups in this list. Edit this list using the Add, Advanced and Remove buttons.

Add	<p>In the preceding single-line field, enter the Windows AD domain name and user group name, and then select Add. If you don't know the exact name, use the Advanced button instead.</p> <p>The format of the entry depends on the AD access mode (see Configuring directory access settings on page 295):</p> <p>Standard: Domain\Group</p> <p>Advanced: cn=group, ou=corp, dc=domain</p>
Advanced	Select Advanced , select the user groups from the list, and then select Add .
Remove	Remove the user groups selected in the monitor list.

Configuring FSSO ports

For FSSO to function properly a small number of TCP and UDP ports must be open through all firewalls on the network. These ports listed in this section assume the default FSSO ports are used.

TCP ports for FSSO agent with client computers

Windows AD records when users log on but not when they log off. For best performance, Fortinet Single Sign On Agent monitors when users log off. To do this, Fortinet Single Sign On Agent needs read-only access to each client computer's registry over TCP port 139 or 445. Open at least one of these ports — ensure it is not blocked by firewalls.

If it is not feasible or acceptable to open TCP port 139 or 445, you can turn off Fortinet Single Sign On Agent logoff detection. To do this, set the Collector agent **workstation verify interval** to 0. The FSSO Collector Agent assumes that the logged on computer remains logged on for the duration of the Collector agent dead entry timeout interval — by default this is eight hours.

Configuring ports on the collector agent computer

On the computer where you install the Collector agent, you must make sure that the firewall does not block the listening ports for the FortiGate unit and the DC Agent. By default, these are TCP port 8000 and UDP port 8002. For more information about setting these ports, see [Configuring FSSO advanced settings on page 305](#).

Configuring alternate user IP address tracking

In environments where user IP addresses change frequently, you can configure Fortinet Single Sign On Agent to use an alternate method to track user IP address changes. Using this method, Fortinet Single Sign On Agent responds more quickly to user IP address changes because it directly queries workstation IP addresses to match users and IP addresses.

This feature requires FSAE version 3.5.27 or later, Fortinet Single Sign On Agent any version, and FortiOS 3.0 MR7 or later.

To configure alternate user IP address tracking:

1. On the computer where the Collector agent is installed, go to **Start > Run**.
2. Enter `regedit` or `regedt32` and select **OK**.
The Registry Editor opens.
3. Find the registry key `HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\collectoragent`.
4. Set the `supportFSAEauth` value (dword) to `00000001`.
If needed, create this new dword.
5. Close the Registry Editor.
6. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
7. Select **Apply**.
The Fortinet Single Sign On Agent service restarts with the updated registry settings.

Viewing FSSO component status

It is important to know the status of both your Collector agents and DC agents.

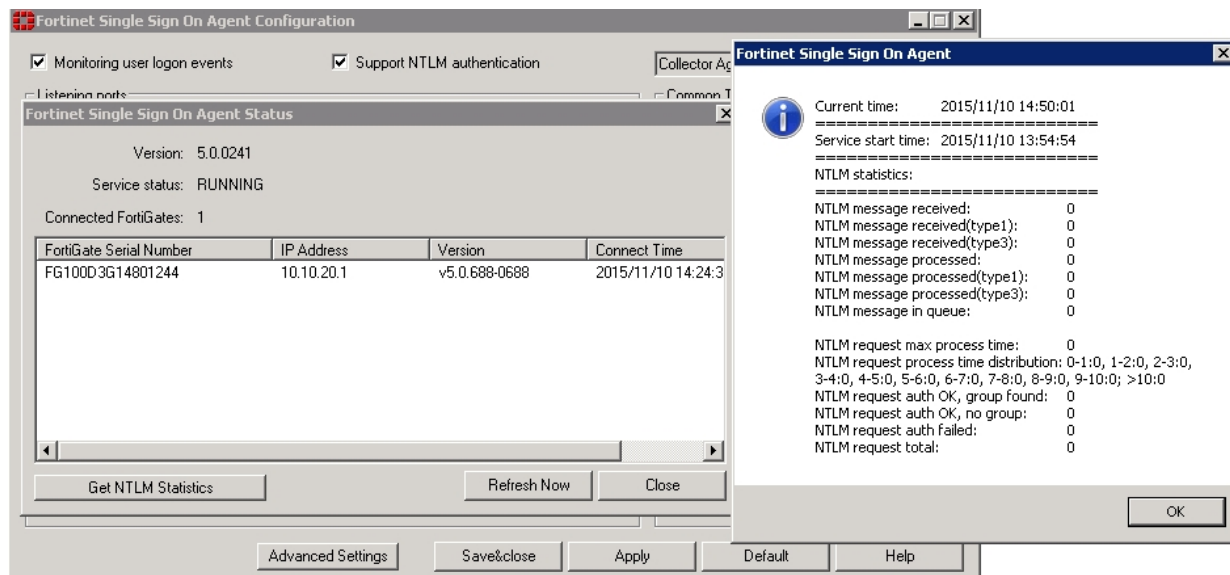

Viewing collector agent status

Use the **Show Service Status** to view your Collector agent information in the Status window. The Status window displays:

- the version of the software
- the status of the service
- the number of connected FortiGate units
- connected FortiGate information such as serial number, IP address, and connect time

To view Collector agent status:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Service Status**.
The Fortinet Single Sign On Collector agent Status window opens.
3. Optionally select **Get NTLM statistics** in the Status window to display NTLM information such as number of messages received, processed, failed, in the queue.

Viewing DC agent status

Use the **Show Monitored DCs** to view the status of DC agents.

To view domain controller agent status:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.
For each DC Agent, the following information is displayed:
 - IP address
 - number of logon events received
 - the last logon event
 - when last logon was received

To change which DC agents are monitored or change the working mode for logon event monitoring, select **Select DC to Monitor**

DC Agent Status			
Active DC Agents: 1			
IP Address	# Logon Events	Last Logon Event Received	Received at
10.10.20.3	350	win2k8r2/KEEPALIVE/5.0.0241	2015/11/10 14:51:11
<div> <div>Select DC to Monitor...</div> <div>Refresh Now</div> <div>Close</div> </div>			

Configuring the FSSO TS agent for Citrix

The FSSO TS agent works with the same FSSO Collector agent that is used for integration with Windows Active Directory. Install the Collector agent first. Follow the Collector agent installation procedure in [Collector agent installation on page 286](#).

FortiOS 5.6 supports FSSO DC/TS Agent v.5.x.

Configuration steps include:

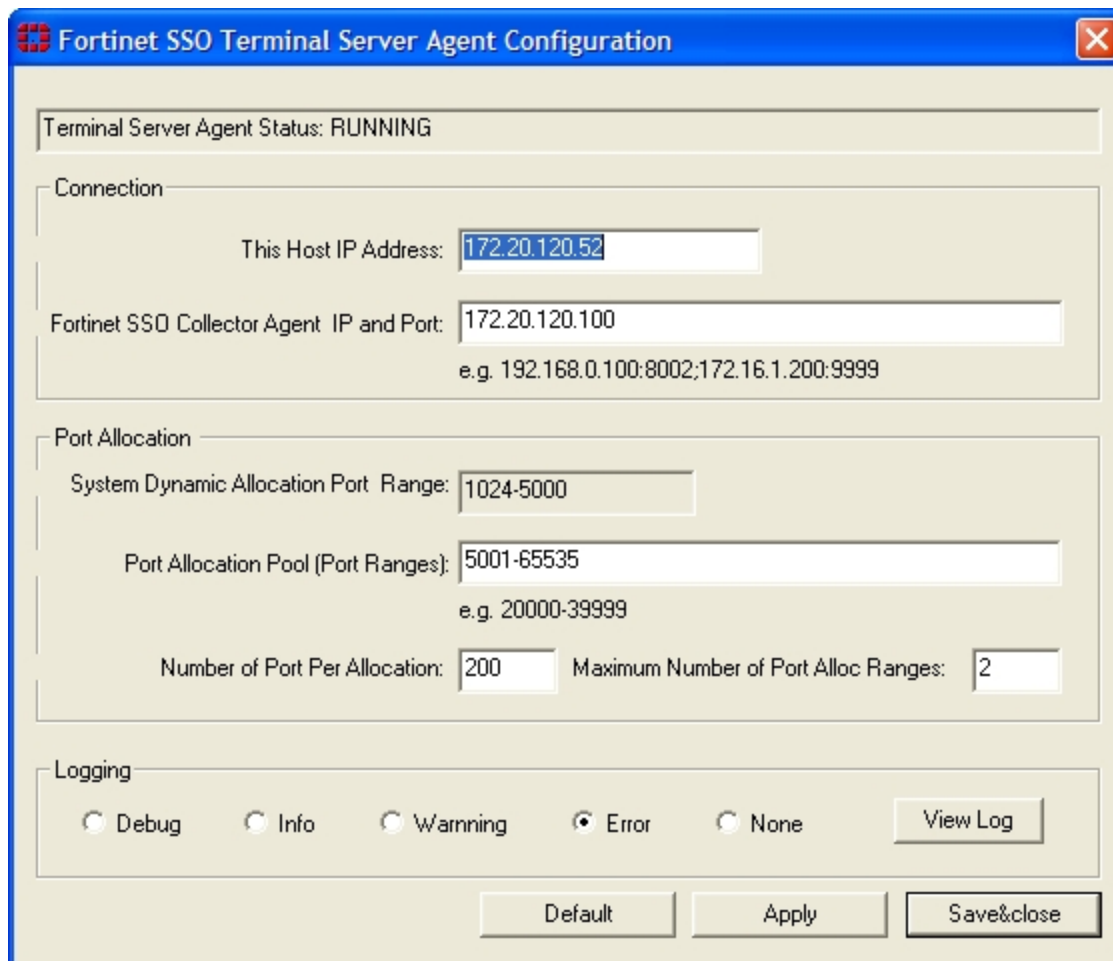

- Install the Fortinet Citrix FSSO agent on the Citrix server.
- Install the Fortinet FSSO collector on a server on the network.
- Add the Citrix FSSO agent to the FortiGate single-sign-On configuration.
- Add Citrix FSSO groups and users to an FSSO user group.
- Add an FSSO identity-based security policy that includes the Citrix FSSO user groups.

To change the TS agent configuration, select from the Start menu **Programs > Fortinet > Fortinet Single Sign-On Agent > TSAgent Config**. In addition to the host and Collector agent IP addresses that you set during installation, you can adjust port allocations for Citrix users. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

Fortinet SSO Collector Agent IP and Port needs to point to the current configured listening port on the collector which is port 8002 by default. Though it may be configured to a custom port.

Configuring the TS agent

The image shows the 'Fortinet SSO Terminal Server Agent Configuration' dialog box. It has a blue title bar with the Fortinet logo and a close button. The main area is divided into sections: 'Terminal Server Agent Status: RUNNING', 'Connection', 'Port Allocation', and 'Logging'. In the 'Connection' section, 'This Host IP Address' is set to '172.20.120.52' and 'Fortinet SSO Collector Agent IP and Port' is '172.20.120.100'. The 'Port Allocation' section shows 'System Dynamic Allocation Port Range' as '1024-5000', 'Port Allocation Pool (Port Ranges)' as '5001-65535', 'Number of Port Per Allocation' as '200', and 'Maximum Number of Port Alloc Ranges' as '2'. The 'Logging' section has radio buttons for 'Debug', 'Info', 'Warning', 'Error' (selected), and 'None', along with a 'View Log' button. At the bottom are 'Default', 'Apply', and 'Save&close' buttons.

Fortinet SSO Terminal Server Agent Configuration

Terminal Server Agent Status: RUNNING

Connection

This Host IP Address: 172.20.120.52

Fortinet SSO Collector Agent IP and Port: 172.20.120.100
e.g. 192.168.0.100:8002;172.16.1.200:9999

Port Allocation

System Dynamic Allocation Port Range: 1024-5000

Port Allocation Pool (Port Ranges): 5001-65535
e.g. 20000-39999

Number of Port Per Allocation: 200 Maximum Number of Port Alloc Ranges: 2

Logging

☐ Debug ☐ Info ☐ Warning ☒ Error ☐ None View Log

Default Apply Save&close

Configuring FSSO with Novell networks

You need to configure the eDirectory agent for it to communicate with eDirectory servers. You may have provided some of this information during installation.

This section includes:

- [Configuring the eDirectory agent](#)
- [Adding an eDirectory server](#)
- [Configuring a group filter](#)

Configuring the eDirectory agent

You need to configure the eDirectory agent for it to communicate with eDirectory servers.

To configure the eDirectory agent:

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. The eDirectory Agent Configuration Utility dialog opens. Enter the following information and select **OK**.

eDirectory Authentication

Username	Enter a username that has access to the eDirectory, using LDAP format.
Password	Enter the password.
Listening port	Enter the TCP port on which Fortinet Single Sign On Agent listens for connections from FortiGate units. The default is 8000. You can change the port if necessary.
Refresh interval	Enter the interval in seconds between polls of the eDirectory server to check for new logons. The default is 30 seconds.

FortiGate Connection Authentication

Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the eDirectory Agent.
Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 15 characters. The default password is "FortinetCanada".
User logon Info Search Method	Select how the eDirectory agent accesses user logon information: LDAP or Native (Novell API). LDAP is the default. If you select Native , you must also have the Novell Client installed on the PC.

Logging

Log file size limit (MB)	Enter the maximum size for the log file in MB.
View Log	View the current log file.
Dump Session	List the currently logged-on users in the log file. This can be useful for troubleshooting.
Log level	Select Debug , Info , Warning or Error as the minimum severity level of message to log or select None to disable logging.

eDirectory Server List

Add	Add an eDirectory server. See Adding an eDirectory server on page 305 .
Delete	Delete the selected eDirectory server.
Edit	Modify the settings for the selected server.
Set Group Filters...	Select the user groups whose user logons will be reported to the FortiGate unit. This is used only if user groups are not selected on the FortiGate unit.

Adding an eDirectory server

Once the eDirectory agent is configured, you add one or more eDirectory servers.

To add an eDirectory server:

1. In the eDirectory Agent Configuration Utility dialog box (see the preceding procedure, [Configuring the eDirectory agent](#)), select **Add**.
2. The eDirectory Setup dialog box opens. Enter the following information and select OK:

eDirectory Server Address	Enter the IP address of the eDirectory server.
Port	If the eDirectory server does not use the default port 389, clear the Default check box and enter the port number.
Use default credential	Select to use the credentials specified in the eDirectory Configuration Utility. See Configuring the eDirectory agent on page 303 . Otherwise, leave the check box clear and enter a username and Password below.
User name	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

Configuring a group filter

The eDirectory agent sends user logon information to the FortiGate unit for all user groups unless you either configure an LDAP server entry for the eDirectory on the FortiGate unit and select the groups that you want to monitor or configure the group filter on the eDirectory agent.

If both the FortiGate LDAP configuration and the eDirectory agent group filter are present, the FortiGate user group selections are used.

To configure the group filter:

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. Select **Set Group Filters**.
3. Do one of the following:
 - Enter group names, then select **Add**.
 - Select **Advanced**, select groups, and then select **Add**.
4. Select **OK**.

Configuring FSSO advanced settings

Depending on your network topologies and requirement, you may need to configure advanced settings in the FSSO Collector agent. To do so, from the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**, then from the **Common Tasks** section, select **Advanced Settings**.

This section include :

- [General settings](#)
- [Citrix/Terminal server](#)
- [Exchange server](#)
- [RADIUS accounting](#)

General settings

In the General tab, enter the following information and select **OK**.

Worker thread count	Number of threads started in the CA process. Default is 128 on CA version 5.0.0241.
Maximum FortiGate connections	Number of FortiGates can be connected to the CA. Default is 64.
Group look-up interval	The interval in seconds to lookup users/groups. If an AD group membership of currently logged on user, CA can detect this and update information on the FortiGate. Enter 0 for no checking.
Windows security Event logs	Choose the event logs to poll.
Event IDs to poll	<p>The default set (0) includes Kerberos authentication event logs : 672 for Windows server 2003, 4768 for Windows server 2008 and 2012 and NTLM authentication event logs : 680 for Windows server 2003, 4776 for Windows server 2008 and 2012. The extended set (1) includes Kerberos service ticket event logs : 673 for Windows server 2003, 4769 for Windows server 2008 and 2012. Service tickets are obtained whenever a user or computer accesses a server on the network.</p> <p>List the event ids separated by ",".</p>
Workstation Check	Optionally enable Use WMI to check user logoff for the collector agent to query whether users is still logged on.
Workstation Name Resolution Advance Options	
Alternative DNS server(s)	Collector Agent uses the DNS server configured on the machine it is running on by default. If CA should use another DNS server then one or more alternative DNS server can be configured here.
Alternative workstation suffix(es)	If only host name is available CA uses the default domain suffix to build a FQDN for DNS queries. In case CA should use a different suffix, it can be configured as well.

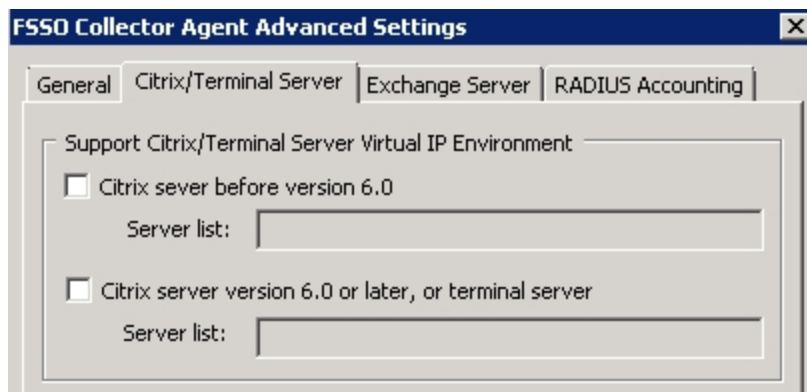

The screenshot shows the 'FSSO Collector Agent Advanced Settings' dialog box with the 'Citrix/Terminal Server' tab selected. The 'General' tab is also visible. The settings are as follows:

- Worker thread count: 128
- Maximum FortiGate connections: 64
- Group lookup interval (in seconds): 0 (0 for no checking)
- Windows Security Event Logs:
 - Event IDs to poll: 0 (0:default set, 1:extended set, or list the eventids separated by ';')
- Workstation Check:
 - ☒ Use WMI to check user logoff
- Workstation Name Resolution Advanced Options:
 - Alternative DNS server(s):
 - Alternative workstation suffix(es):

Citrix/Terminal server

In the Citrix/Terminal server tab, enter the following information and select **OK**.

Support Citrix/Terminal Server Virtual IP Environment	When Citrix server are configured with VIP, CA can get user logon events from these server. Citrix changed their interface and data format so version of Citrix server is important.
Citrix server before version 6.0	Enable this option if you Citrix server version is before 6.0.
Server list	Enter the list of servers separated by colon.
Citrix server version 6.0 or later, or Terminal Server	Enable this option if you Citrix server version is 6.0 or later.
Server list	Enter the list of servers separated by colon.

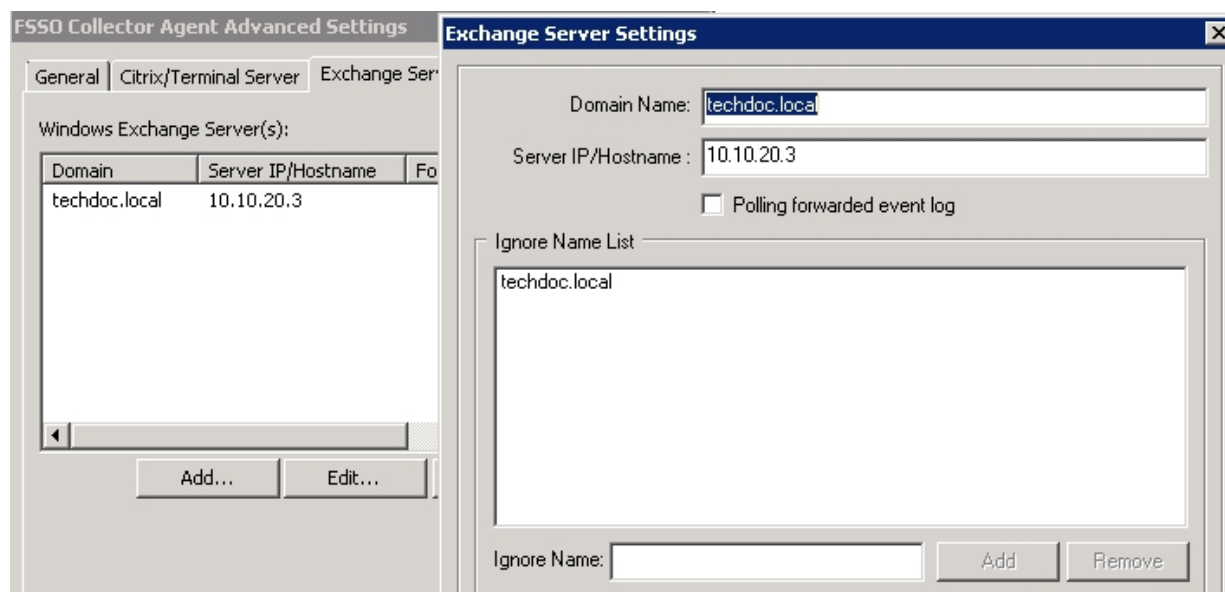

Exchange server

FSSO supports monitoring Microsoft Exchange server. This is useful for situation that the user use the domain account to access their email, but client device might or might not be in the domain. Support for Exchange server is configured on the Back-end FSSO collector agent under **Advanced Settings > Exchange Server**.

Select **Add** and enter the following information and select **OK**.

Domain Name	Enter your domain name.
Server IP/Hostname	Enter the IP address or the hostname of your exchange server.
Polling forwarded event log	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
Ignore Name	Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ES-EventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to. To do so, enter the domain name in the Ignore Name field and select Add .

RADIUS accounting

A RADIUS server must be configured in your network to send accounting messages to the Collector Agent which can be configured to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the Collector Agent. User group names do not need to be added for all users, only to the accounts of users who will use RADIUS Accounting feature on the Collector Agent.
- Configure your accounting system to send RADIUS Start records to the Collector Agent.

The Collector Agent should be configured to listen for RADIUS accounting messages as following.

RADIUS Accounting Server	
Enable RADIUS Accounting Server	Enable this option to allow the CA to gather information about authenticated users via a RADIUS server and send these information to the FortiGate unit for monitoring.
Listen port	The port on which CA listens for RADIUS accounting messages. Default RADIUS accounting is 1813, but if RADIUS server sends accounting messages on different port, value can be configured here.
Shared secret	Common secret between CA and RADIUS server.

Default domain name

This should be the AD domain for which this CA is configured. In this case user name in RADIUS accounting message can be in simple format like user1.

If this value is empty, then user name in RADIUS accounting message must be in one of these formats user1@domain, Domain\user1 or domain/user1.

CA will use user name and domain to query group membership of user. Client IP address (Framed IP) should also be in RADIUS accounting message, so that CA can forward user name, IP address and groups to the FortiGate.

Configuring FSSO on FortiGate units

To configure your FortiGate unit to operate with agent-based FSSO, you

- Configure any access to LDAP servers that might be necessary. Skip this step if you are using FSSO Standard mode. See [Configuring LDAP server access on page 310](#).
- Specify the Collector agent or Novell eDirectory agent that will provide user logon information. See [Specifying your collector agents or Novell eDirectory agents on page 312](#).
- Add Active Directory user groups to FortiGate user groups. See [Creating FSSO user groups on page 313](#).
- Create security policies for FSSO-authenticated groups. See [Creating security policies on page 313](#).
- Optionally, specify a guest security policy to allow guest access. See [Enabling guest access through FSSO security policies on page 315](#).

Configuring LDAP server access

LDAP access is required if your network has a Novell eDirectory agent or a Collector agent using Windows Advanced AD access mode. If you are using FSSO Standard mode, go to [Specifying your collector agents or Novell eDirectory agents on page 312](#).

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**. The default common name identifier is **cn**. This is correct for most LDAP servers. However some servers use other identifiers such as **uid**.
4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished

Name is dc=techdoc,dc=local

5. Select **Fetch DN**, this will fetch the Windows AD directory.

6. Set **Bind Type** to **Regular**.
7. In the **User DN** field, enter the administrative account name that you created for FSSO. For example, if the account is administrator, enter "administrator@techdoc.local".
8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
 - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
 - In the **Certificate** field, select the appropriate certificate for authentication.

Note that you need to configure the Windows AD for secure connection accordingly.
10. Select **OK**.
11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.

To configure LDAP for FSSO - CLI example:

```
config user ldap
```

```

edit LDAP
    set server 10.10.20.3
    set cnid sAMAccountName
    set dn dc=techdoc,dc=local
    set type regular
    set username administrator@techdoc.local
    set password <your_password>
next
end

```

Specifying your collector agents or Novell eDirectory agents

You need to configure the FortiGate unit to access at least one Collector agent or Novell eDirectory agent. You can specify up to five servers on which you have installed a Collector or eDirectory agent. The FortiGate unit accesses these servers in the order that they appear in the list. If a server becomes unavailable, the next one in the list is tried.

To specify Collector agents - web-based manager:

1. Go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Under **SSO/Identity**, select **Fortinet Single Sign-On Agent**.
3. Enter a **Name** for the Windows AD server. This name appears in the list of Windows AD servers when you create user groups.
4. Enter the **Server IP/Name** and **Password** of the server where this agent is installed. Maximum name length is 63 characters. For the collector agent, passwords are only required only if you configured the agent to require authenticated access.
If the TCP port used for FSSO is not the default, 8000, you can change the setting in the CLI using the `config user fssso` command. See [Configuring collector agent settings on page 291](#).
5. Set **Collector Agent AD access mode** to **Advanced**, and select the **LDAP Server** you configured previously. See [Configuring LDAP server access on page 310](#).
6. Select the **Users** or **Groups** or **Organizational Units** tab to select the users, groups, OU that you want to monitor.
7. Select **OK**.

Name:
 Primary Agent IP/Name: Password:
 Secondary Agent IP/Name: Password: [More FSSO agents](#)
 LDAP Server: X
 Users/Groups

The screenshot shows the FortiGate web interface. On the left, the 'LDAP Tree' is expanded, showing the hierarchy: dc=techdoc,dc=local. On the right, the 'Users' tab is selected, displaying a table of users. The table has columns for ID, Name, and Full DN. The 'FortiOS Writers' user is highlighted with a green checkmark. At the bottom, a pagination bar shows '1 / 1' and 'Total: 38'.

ID	Name	Full DN
Domain Controllers	Domain Controllers	CN=Domain Controllers,CN=Users,DC=techdoc,DC=local
Domain Guests	Domain Guests	CN=Domain Guests,CN=Users,DC=techdoc,DC=local
Domain Users	Domain Users	CN=Domain Users,CN=Users,DC=techdoc,DC=local
Enterprise Admins	Enterprise Admins	CN=Enterprise Admins,CN=Users,DC=techdoc,DC=local
Enterprise Read-only Domain Controllers	Enterprise Read-only Domain Controllers	CN=Enterprise Read-only Domain Controllers,CN=Users,DC=techdoc,DC=local
Event Log Readers	Event Log Readers	CN=Event Log Readers,CN=Builtin,DC=techdoc,DC=local
FortiOS Writers	FortiOS Writers	CN=FortiOS Writers,CN=Users,DC=techdoc,DC=local
Group Policy Creator Owners	Group Policy Creator Owners	CN=Group Policy Creator Owners,CN=Users,DC=techdoc,DC=local
Guests	Guests	CN=Guests,CN=Builtin,DC=techdoc,DC=local
IIS_IUSRS	IIS_IUSRS	CN=IIS_IUSRS,CN=Builtin,DC=techdoc,DC=local

To specify the FSSO collector agent - CLI:

In this example, the SSO server name is techdoc and the LDAP server is LDAP.

```
config user fssso
  edit techdoc
    set ldap-server LDAP
    set password <your_password>
    set server 10.10.20.3
    set port 8000
  end
```

Creating FSSO user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User Groups**.
2. Select **Create New**.
The New User Group dialog box opens.
3. In the **Name** box, enter a name for the group, FSSO_Internet_users for example.
4. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
5. In **Members**, select the required **FSSO** groups.
6. Select **OK**.

To create the FSSO_Internet-users user group - CLI :

```
config user group
  edit FSSO_Internet_users
    set group-type fssso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
    CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fssso_group`, and the FSSO RADIUS server is `fssso_rad_server`.

To configure an FSSO authentication security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information.

Incoming Interface	port1
Source Address	company_network
Source User(s)	fsso_group
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
NAT	ON
UTM Security Profiles	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
Log Allowed Traffic	ON. Select Security Events .

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr company_network
    set dstaddr all
    set action accept
    set groups fsso_group
    set schedule always
    set service HTTP HTTPS FTP TELNET
    set nat enable
  end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Users belonging to multiple groups

Before FSSO 4.0 MR3, if a user belonged to multiple user groups, the first security policy to match any group that user belonged to was the only security policy applied. If that specific group did not have access to this protocol or resource where another group did, the user was still denied access. For example, `test_user` belongs to `group1` and `group2`. There are two FSSO authentication policies — one matches `group1` to authenticate FTP traffic and one matches `group2` to authenticate email traffic. The `group1` policy is at the top of the list of policies. If `test_user` wants to access an email server, the first policy encountered for a group `test_user` belongs to is the `group1` policy which does not allow email access and `test_user` is denied access. This is despite the next policy allowing access to email. If the order was reversed in this case, the traffic would be matched and the user's traffic would be allowed through the firewall. However if the policy order was reversed, FTP traffic would not be matched.

As of FSSO 4.0 MR3, if a user belongs to multiple groups multiple then attempts to match the group are attempted if applicable. Using the above example, when the attempt to match the `group1` policy is made and fails, the next policy with a group that `test_user` is a member of is attempted. In this case, the next policy is matched and access is granted to the email server.

When configuring this example the only difference between the policies is the services that are listed and the FSSO user group name.

Authenticating through multiple groups allows administrators to assign groups for specific services, and users who are members of each group have access to those services. For example there could be an FTP group, an email group, and a Telnet group.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to the Windows AD or Novell network and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and protection profile that apply to guest users — typically guests receive reduced access to a reduced set of services.

IPv6 support for FSSO

FortiGate FSSO supports connecting to an FSSO agent over IPv6 and collecting and sending IPv6 details about endpoints. This is enforced in the same manner as IPv4 FSSO traffic.

Syntax

```
config user fsso
  edit <fsso agent name>
    set source-ip6 <IPv6 address for source>
  end
```

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO-related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For

more information on firewall logging, see "Enabling security logging". For more information on logging, see the FortiOS Handbook Log and Reporting guide.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events need, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged. While this extra information is useful, you must

To enable event logging:

1. Go to **Log & Report > Log Settings**.
2. In **Event Logging**, select:

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

3. Optionally you can enable any or all of the other logging event options.
4. Select **Apply**.

Authentication log messages

#	Date/Time	Level	Source	Action	Status	Message	Timestamp
1	06:15:24	Information	TELBAR (10.10.20.7)	FSSO-logout		FSSO-logout event from techdoc: user TELBAR logged off 10.10.20.7	11/12/2015, 6:15:24 AM
2	11-11 22:22	Information	ADMINISTRATOR (10.10.20.3)	authentication	logout	User ADMINISTRATOR succeeded in logout	11/11/2015, 10:22:15 P
3	11-11 22:22	Information	ADMINISTRATOR (10.10.20.3)	FSSO-logout		FSSO-logout event from techdoc: user ADMINISTRATOR logged off 10.10.20.3	11/11/2015, 10:22:15 P
4	11-11 22:17	Information	ADMINISTRATOR (10.10.20.3)	FSSO-logout		FSSO-logout event from techdoc: user ADMINISTRATOR logged on 10.10.20.3	11/11/2015, 10:17:12 P

1 / 5 [Total: 246]

#	1	Action	FSSO-logout
Date/Time	06:15:24	Dst	techdoc
Level	Information	Log Description	FSSO logout authentication status
Log ID	43015	Message	FSSO-logout event from techdoc: user TELBAR logged off 10.10.20.7
Source	TELBAR (10.10.20.7)	Sub Type	user
Timestamp	11/12/2015, 6:15:24 AM	User	TELBAR
Virtual Domain	root		

List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed

Message ID	Severity	Description
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Log and Reporting guide.

Using filters

Logon events are detected by the FSSO CA by monitoring the Security Event logs. Additional logon event filters, such as ServiceName and ServiceID, have been implemented so as to avoid instances of conflicting security events, where existing FSSO logon user information could be overwritten and impact user connectivity.

The problem arises when a scenario such as the following occurs:

1. **User1** logs on to **PC1** on 1.1.1.1, which is logged as a successful Kerberos logon event with an ID of 4769.
2. The FortiGate creates an authenticated FSSO user log entry for **User1/1.1.1.1**.
3. **User1** then maps a network drive and uses credentials for **User2** to logon to the same PC (**PC1**).
4. The FortiGate sees this as a separate logon to **PC1** by a new user, **User2**. As a result, the log entry is updated to **User2/1.1.1.1**.
5. If **User2** is a member of a different user group to **User1** (i.e. has different access permissions), **User1** could lose access to their network resources.

The new filter makes the CA ignore the event log created when **User1** mapped a network drive, meaning that the original entry for **User1** will not be changed.

While this is a useful feature, it is highly recommended to test filters in a redundant test environment.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see [Troubleshooting FSSO on page 318](#).

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:

```
diagnose debug authd fsso list
```

4. Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 10.10.20.3 User: ADMINISTRATOR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
Workstation: WIN2K8R2.TECHDOC.LOCAL MemberOf: FortiOS_Writers
IP: 10.10.20.7 User: TELBAR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
Workstation: TELBAR-PC7.TECHDOC.LOCAL
Total number of logons listed: 2, filtered: 0
----end of FSSO logons----
```

The exact information will vary based on your installation.

5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fsso server-status
FGT# Server Name Connection Status Version
-----
techdoc          connected FSSO 5.0.0241
```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- [General troubleshooting tips for FSSO](#)
- [Users on a particular computer \(IP address\) cannot access the network](#)
- [Guest users do not have access to network](#)
- [Can't find the DC agent service](#)
- [User logon events not received by FSSO collector agent](#)
- [Mac OS X users can't access external resources after waking from sleep mode](#)

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.
FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP) 8000, and 8002.
- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit.
If not the Collector agent does not have this amount of bandwidth, information FSSO information may not reach the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.

Users on a particular computer (IP address) cannot access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the

authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediately logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don't have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `SSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

Can't find the DC agent service

The DCagent service can't be found in the list of regular windows services. This is because it has no associated Windows service.

Instead DCagent is really `dcagent.dll` and is located in the `Windows\system32` folder. This DLL file is loaded when windows boots up and it intercepts all logon events processed by the domain controller to send these events to the Collector agent (CA).

Solution

To verify that the DCagent is installed properly

1. Check that `DCagent.dll` exists in `Windows\system32` folder.
2. Check that the registry key exists: `[HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\dcagent]`

If both exist, the DCagent is properly installed.

User logon events not received by FSSO collector agent

When a warning dialog is present on the screen on the Collector agent computer, the Collector agent will not receive any logon events. Once the dialog has been closed normal operation will resume.

If polling mode is enabled, it is possible the polling interval is too large. Use a shorter polling interval to ensure the collector agent is capturing all logon events.

The polling interval can only be adjusted using the firewall-embedded agent itself, not on agents deployed to member servers.

If NetAPI polling mode is enabled, consider switching to Event logs or Event Logs using WMI polling as it provides better accuracy.

Mac OS X users can't access external resources after waking from sleep mode

When client computers running Mac OS X (10.6.X and higher) wake up from sleep mode, the user must authenticate again to be able to access external resources. If the user does not re-authenticate, the user will maintain access to internal web sites, but will be unable to access any external resources.

This issue is caused by Mac OS X not providing sufficient information to the FSSO. This results in the FortiGate blocking access to the user because they cannot be authenticated.

Solution

The security settings on client computer(s) must be configured to require that a username and password be entered when exiting sleep mode or screen saver. With this feature enabled in Mac OS X, the FortiGate will receive the authentication information it requires to authenticate the user and allow them access.

Note that if the user reverts their settings to disable the password requirement, this will cause the issue to reappear.

SSO using RADIUS accounting records

A FortiGate unit can authenticate users transparently who have already authenticated on an external RADIUS server. Based on the user group to which the user belongs, the security policy applies the appropriate UTM profiles. RADIUS SSO is relatively simple because the FortiGate unit does not interact with the RADIUS server, it only monitors RADIUS accounting records that the server forwards (originating from the RADIUS client). These records include the user's IP address and user group.

After the initial set-up, changes to the user database, including changes to user group memberships, are made on the external RADIUS server, not on the FortiGate unit.

This section describes:

- [User's view of RADIUS SSO authentication](#)
- [Configuration overview](#)
- [Configuring the RADIUS server](#)
- [Creating the FortiGate RADIUS SSO agent](#)
- [Defining local user groups for RADIUS SSO](#)
- [Creating security policies](#)
- [Example - webfiltering for student and teacher accounts](#)

User's view of RADIUS SSO authentication

For the user, RADIUS SSO authentication is simple:

- The user connects to the RADIUS server and authenticates.
- The user attempts to connect to a network resource that is reached through a FortiGate unit. Authentication is required for access, but the user connects to the destination without being asked for logon credentials because the FortiGate unit knows that the user is already authenticated. FortiOS applies UTM features appropriate to the user groups that the user belongs to.

Configuration overview

The general steps to implement RADIUS Single Sign-On are:

1. If necessary, configure your RADIUS server. The user database needs to include user group information and the server needs to send accounting messages.
2. Create the FortiGate RADIUS SSO agent.
3. Define local user groups that map to RADIUS groups.
4. Create a security policy which specifies the user groups that are permitted access.

Configuring the RADIUS server

You can configure FortiGate RSSO to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the FortiOS unit. User group names do not need to be added for all

users, only to the accounts of users who will use RSSO feature on the FortiGate unit.

- Configure your accounting system to send RADIUS Start records to the FortiOS unit. You can send the RADIUS Start records to any FortiGate network interface. If your FortiGate unit is operating with virtual domains (VDOMs) enabled, the RADIUS Start records must be sent to a network interface in the management VDOM.

IPv6 RADIUS support

RADIUS authentication is supported with IPv6, allowing administrators to configure an IPv6 RADIUS server on the FortiGate for IPv6 RADIUS authentication traffic to pass between the server and FortiGate.

Note that while you can set the primary RADIUS server's IPv6 address, the source IP address for communications to the RADIUS server cannot be configured as IPv6.

Syntax

Allow IPv6 access on an interface:

```
config system interface
  edit <name>
    config ipv6
      set ip6-allowaccess {ping | https | ssh | snmp | http | telnet | fgfm | capwap}
      set ip6-address <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx/xxx>
    next
  next
end
```

Configure the IPv6 RADIUS server:

```
config user radius
  edit <name>
    set server <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx>
    ...
  next
end
```

Creating the FortiGate RADIUS SSO agent

Once you define a RADIUS SSO (RSSO) agent, the FortiGate unit will accept user logon information from any RADIUS server that has the same shared secret. You can create only one RSSO agent in each VDOM.

Before you create the RSSO agent, you need to allow RADIUS accounting information on the interface that connects to the RADIUS server.

To enable RADIUS access on the interface - web-based manager:

1. Go to **Network > Interfaces** and edit the interface to which the RADIUS server connected.
2. Select **Listen for RADIUS Accounting Messages**.
3. Select **OK**.

To enable RADIUS access on the interface - CLI:

In this example, the port2 interface is used.

```
config system interface
    edit port2
        set allowaccess radius-acct
    end
```

To create a RADIUS SSO agent:

1. Go to **[[[Undefined variable FortiOSGUIVariables.User & Device > Single Sign-On]]]** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On Agent**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.

To create a RADIUS SSO agent - CLI:

```
config user radius
    edit RSSO_Agent
        set rso enable
        set rso-validate-request-secret enable
        set rso-secret <your secret>
        set rso-radius-response enable
    end
```

Selecting which RADIUS attributes are used for RSSO

For RADIUS SSO to work, FortiOS needs to know the user's endpoint identifier (usually IP address) and RADIUS user group. There are default RADIUS attributes where FortiOS expects this information, but you can change these attributes in the `config user radius` CLI command.

RSSO information and RADIUS attribute defaults

RSSO Information	RADIUS Attribute	CLI field
Endpoint identifier	Calling-Station-ID	<code>rso-endpoint-attribute</code>
Endpoint block attribute	Called-Station-ID	<code>rso-endpoint-block-attribute</code>
User group	Class	<code>sso-attribute</code>
User	Prefix	<code>delegated-IPv6-prefix</code>
User	Prefix	<code>framed-IPv6-prefix</code>

The Endpoint block attribute can be used to block or allow a user. If the attribute value is set to the name of an attribute that indicates whether to block or allow, FortiOS blocks or allows respectively all traffic from that user's IP address. The RSSO fields are visible only when `rso` is set to `enable`.

The Prefix attributes allow for RSSO to provide a /56 prefix for DSL customers. All devices connected from the same location (/56 per subscriber) can be mapped to the same profile without the need to create multiple /64 or smaller entries.

Override SSO attribute

Prior to FortiOS 5.4, when receiving a new start message with a different group name for the same user, and a different IP address such as for a roaming mobile device, the original process was to override all group name information to the latest group name received from the latest start message.

You can disable this override when needed. The default behavior keeps the original design.

To enable or disable overriding SSO attribute - CLI

```
config user radius
edit <name>
set rso <enable>
set sso-attribute-value-override {enable | disable} Enable/disable override of old attribute value with new value for the same endpoint.
```

Configuring logging for RSSO

In the `config user radius` CLI command, you can set the following flags in the `rso-log-flags` field to determine which types of RSSO-related events are logged:

- `protocol-error` — A RADIUS protocol error occurred.
- `profile-missing` — FortiOS cannot find a user group name in a RADIUS start message that matches the name of an RSSO user group in FortiOS.
- `accounting-stop-missed` — a user context entry expired without FortiOS receiving a RADIUS Stop message.
- `accounting-event` — FortiOS did not find the expected information in a RADIUS record.
- `endpoint-block` — FortiOS blocked a user because the RADIUS record's endpoint block attribute had the value "Block".
- `radiusd-other` — Other events, described in the log message.

Defining local user groups for RADIUS SSO

You cannot use RADIUS user groups directly in security policies. Instead, you create locally-defined user groups on the FortiGate unit and associate each of them with a RADIUS user group.

To define local user groups for RADIUS SSO:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

To define local user groups for RADIUS SSO:

This example creates an RSSO user group called RSSO-1 that is associated with RADIUS user group "student".

```
config user group
edit RSSO-1
set group-type rso
set sso-attribute-value student
end
```

Creating security policies

RADIUS SSO uses regular identity-based security policies. The RSSO user group you specify determines which users are permitted to use the policy. You can create multiple policies if user groups can have different UTM features enabled, different permitted services, schedules, and so on.

To create a security policy for RSSO - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information.

Incoming Interface	as needed
Source Address	as needed
Source User(s)	Select the user groups you created for RSSO. See Defining local user groups for RADIUS SSO on page 324 .
Outgoing Interface	as needed
Destination Address	all
Schedule	as needed
Service	as needed
Action	ACCEPT
Enable NAT	Selected
Security Profiles	Select security profiles appropriate for the user group.

4. Select **OK**.

To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.

5. Select **OK**.

To create a security policy for RSSO - CLI:

In this example, an internal network to Internet policy enables web access for members of a student group and activates the appropriate UTM profiles.

```
config firewall policy
edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set dstaddr "all"
    set action accept
    set rso enable
    set groups "RSSO-student"
```

```

set schedule always
set service HTTP HTTPS
set nat enable
set utm-status enable
set av-profile students
set webfilter-profile students
set spamfilter-profile students
set dlp-sensor default
set ips-sensor default
set application-list students
set profile-protocol-options "default"
end

```

Example - webfiltering for student and teacher accounts

The following example uses RADIUS SSO to apply web filtering to students, but not to teachers. Assume that the RADIUS server is already configured to send RADIUS Start and Stop records to the FortiGate unit. There are two RADIUS user groups, **students** and **teachers**, recorded in the default attribute **Class**. The workstations are connected to port1, port2 connects to the RADIUS server, and port3 connects to the Internet.

Configure the student web filter profile:

1. Go to **Security Profiles > Web Filter** and select **Create New** (the "+" button).
2. Enter the following and select **OK**.

Name	student
Inspection Mode	Proxy
FortiGuard Categories	Enable. Right-click the Potentially Liable category and select Block . Repeat for Adult/Mature Content and Security Risk .

Create the RADIUS SSO agent:

1. Go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Under **SSO/Identity**, select **RADIUS Single Sign-On Agent**.
3. Enter a name for the RSSO Agent.
4. Enable **Use RADIUS Shared Secret** and enter the RADIUS server's shared secret.
5. Enable **Send RADIUS Responses**.
6. Select **OK**.

Define local user groups associated with the RADIUS SSO user groups:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following and select **OK**.

Name	RSSO-students
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	students

3. Select **Create New**, enter the following and select **OK**.

Name	RSSO-teachers
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	teachers

Create a security policy for students:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter

Incoming Interface	port1
Source Address	all
Source User(s)	RSSO-students
Source Device Type	All
Outgoing Interface	port3
Destination Address	all
Schedule	always
Service	HTTP, HTTPS
Action	ACCEPT
NAT	ON
Security Profiles	Enable AntiVirus, Web Filter, IPS. In Web Filter, select the student profile.

3. Select **OK**.

Create a security policy for teachers:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter

Incoming Interface	port2
Source Address	all
Source User(s)	RSSO-teachers
Source Device Type	All
Outgoing Interface	port3

Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	ON
Security Profiles	Enable AntiVirus and IPS.

3. Select **OK**.

Monitoring authenticated users

This section describes how to view lists of currently logged-in firewall and VPN users. It also describes how to disconnect users.

The following topics are included in this section:

- [Monitoring firewall users](#)
- [Monitoring SSL VPN users](#)
- [Monitoring IPsec VPN users](#)
- [Monitoring users quarantine](#)

Monitoring firewall users

To monitor firewall users, go to **Monitor > Firewall User Monitor**.

 Refresh	 De-authenticate						
 User Name	 User Group	 Policy ID	 Duration	 IP Address	 Traffic Volume	 Method	
user3	Group1	2	0 day(s) 0 hour(s) 4 minute(s)	10.11.101.20	35 KB	FW-auth	
user4	Group1	2	0 day(s) 3 hour(s) 4 minute(s)	10.11.101.101	421 KB	FW-auth	

You can de-authenticate a user by selecting the Delete icon for that entry.

You can filter the list of displayed users by selecting the funnel icon for one of the column titles or selecting **Filter Settings**.

Optionally, you can de-authenticate multiple users by selecting them and then selecting **De-authenticate**.

Monitoring SSL VPN users

You can monitor web-mode and tunnel-mode SSL VPN users by username and IP address.

To monitor SSL VPN users, go to **Monitor > SSL-VPN Monitor**. To disconnect a user, select the user and then select the **Delete** icon.

<div> Delete</div>					
<input type="checkbox"/>	No.	User	Source IP	Begin Time	Description
<input type="checkbox"/>	1	user2	172.20.120.51	Wed Mar 17 13:17:32 2010	
<input checked="" type="checkbox"/>		Subsession			Tunnel IP:10.0.0.1

The first line, listing the username and IP address, is present for a user with either a web-mode or tunnel-mode connection. The Subsession line is present only if the user has a tunnel mode connection. The **Description** column displays the virtual IP address assigned to the user's tunnel-mode connection.

For more information about SSL VPN, see the FortiOS Handbook SSL VPN guide.

To monitor SSL VPN users - CLI:

To list all of the SSL VPN sessions and their index numbers:

```
execute vpn sslvpn list
```

The output looks like this:

```
SSL-VPN Login Users:
  Index   User   Auth Type   Timeout   From           HTTPS in/out
  0       user1  1           256      172.20.120.51  0/0

SSL-VPN sessions:
  Index   User   Source IP      Tunnel/Dest IP
  0       user2  172.20.120.51  10.0.0.1
```

You can use the Index value in the following commands to disconnect user sessions:

To disconnect a tunnel-mode user

```
execute vpn sslvpn del-tunnel <index>
```

To disconnect a web-mode user

```
execute vpn sslvpn del-web <index>
```

You can also disconnect multiple users:

To disconnect all tunnel-mode SSL VPN users in this VDOM

```
execute vpn ssl del-all tunnel
```

To disconnect all SSL VPN users in this VDOM

```
execute vpn ssl del-all
```

Monitoring IPsec VPN users

To monitor IPsec VPN tunnels in the web-based manager, go to **Monitor > IPsec Monitor**. user names are available only for users who authenticate with XAuth.

You can close a tunnel by selecting the tunnel and right click to select **Bring Down**.

Type	Dialup					
Name	Remote Gateway	Timeout	Status	Incoming Data	Outgoing Data	Username
dialup1_0	172.20.120.51	1116	 Bring Down	79233170 B	171639314 B	user2

For more information, see the FortiOS Handbook IPsec VPN guide.

Monitoring users quarantine

The user quarantine list shows all IP addresses and interfaces blocked by NAC quarantine. The list also shows all IP addresses, authenticated users, senders, and interfaces blocked by data leak prevention (DLP). The system administrator can selectively release users or interfaces from quarantine or configure quarantine to expire after a selected time period.

All sessions started by users or IP addresses on the user quarantine list are blocked until the user or IP address is removed from the list. All sessions to an interface on the list are blocked until the interface is removed from the list.

You can configure NAC quarantine to add users or IP addresses to the user quarantine list under the following conditions:

- **Users or IP addresses that originate attacks detected by IPS** - To quarantine users or IP addresses that originate attacks, enable and configure **Quarantine** in an IPS Filter.
- **Users or IP addresses that are quarantined by Data Leak Prevention** - In a DLP sensor select **Quarantine IP Address** as the action to take.

For more information, see [FortiOS Security Profiles](#) guide.

Users are viewed from **Monitor > Quarantine Monitor**.

Delete	Removes the selected user or IP address from the User Quarantine list.
Remove All	Removes all users and IP addresses from the User Quarantine list.
Search	Search the list for a particular IP address.
Source	The FortiGate function that caused the user or IP address to be added to the User Quarantine list: IPS or Data Leak Prevention.
Created	The date and time the user or IP address was added to the Banned User list.
Expires	The date and time the user or IP address will be automatically removed from the User Quarantine list. If Expires is Indefinite , you must manually remove the user or host from the list.

Examples and troubleshooting

This chapter provides an example of a FortiGate unit providing authenticated access to the Internet for both Windows network users and local users.

The following topics are included in this section:

- [Firewall authentication example](#)
- [LDAP dial-in using member-attribute example](#)
- [RADIUS SSO example](#)
- [Troubleshooting](#)

Firewall authentication example

Example configuration

Overview

In this example, there is a Windows network connected to Port 2 on the FortiGate unit and another LAN, Network_1, connected to Port 3.

All Windows network users authenticate when they logon to their network. Members of the Engineering and Sales groups can access the Internet without entering their authentication credentials again. The example assumes that the Fortinet Single Sign On (FSSO) has already been installed and configured on the domain controller.

LAN users who belong to the Internet_users group can access the Internet after entering their username and password to authenticate. This example shows only two users, User1 is authenticated by a password stored on the FortiGate unit, User2 is authenticated on an external authentication server. Both of these users are referred to as local users because the user account is created on the FortiGate unit.

Creating a locally-authenticated user account

User1 is authenticated by a password stored on the FortiGate unit. It is very simple to create this type of account.

To create a local user - web-based manager:

1. Go to **User & Device > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

User Type	Local User
User Name	User1
Password	hardtoguess
Email Address SMS	(optional)
Enable	Select.

To create a local user - CLI:

```
config user local
edit user1
set type password
set passwd hardtoguess
end
```

Creating a RADIUS-authenticated user account

To authenticate users using an external authentication server, you must first configure the FortiGate unit to access the server.

To configure the remote authentication server - web-based manager:

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**:

Name	OurRADIUSsrv
Primary Server Name/IP	10.11.101.15
Primary Server Secret	OurSecret
Authentication Scheme	Select Use Default Authentication Scheme .

To configure the remote authentication server - CLI:

```
config user radius
edit OurRADIUSsrv
set server 10.11.102.15
set secret OurSecret
set auth-type auto
end
```

Creation of the user account is similar to the locally-authenticated account, except that you specify the RADIUS authentication server instead of the user's password.

To configure a remote user - web-based manager:

1. Go to **User & Device > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

User Type	Remote RADIUS User
User Name	User2
RADIUS server	OurRADIUSsrv
Email Address SMS	(optional)
Enable	Select

To configure a remote user - CLI:

```
config user local
  edit User2
    set name User2
    set type radius
    set radius-server OurRADIUSsrv
  end
```

Creating user groups

There are two user groups: an FSSO user group for FSSO users and a firewall user group for other users. It is not possible to combine these two types of users in the same user group.

Creating the FSSO user group

For this example, assume that FSSO has already been set up on the Windows network and that it uses Advanced mode, meaning that it uses LDAP to access user group information. You need to

- configure LDAP access to the Windows AD global catalog
- specify the collector agent that sends user logon information to the FortiGate unit
- select Windows user groups to monitor
- select and add the Engineering and Sales groups to an FSSO user group

To configure LDAP for FSSO - web-based manager:

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter the following information:

Name	ADserver
Server Name / IP	10.11.101.160
Distinguished Name	dc=office,dc=example,dc=com

Bind Type	Regular
User DN	cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
Password	Enter a secure password.

3. Leave other fields at their default values.
4. Select **OK**.

To configure LDAP for FSSO - CLI"

```
config user ldap
  edit "ADserver"
    set server "10.11.101.160"
    set dn "cn=users,dc=office,dc=example,dc=com"
    set type regular
    set username "cn=administrator,cn=users,dc=office,dc=example,dc=com"
    set password set_a_secure_password
  next
end
```

To specify the collector agent for FSSO - web-based manager:

1. Go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Under **SSO/Identity**, select **Fortinet Single Sign-On Agent**.
3. Enter a **Name** (in this example, WinGroups) for the Windows AD server. This name appears in the list of Windows AD servers when you create user groups.
4. Enter the **Server IP/Name** (in this example, 10.11.101.160) and **Password** (in this example, fortinet_canada) of the server where this agent is installed. Maximum name length is 63 characters. For the collector agent, passwords are only required only if you configured the agent to require authenticated access.
If the TCP port used for FSSO is not the default, 8000, you can change the setting in the CLI using the `config user fssso` command. See [Examples and troubleshooting on page 332](#).
5. Set **Collector Agent AD access mode** to **Advanced**, and select the **LDAP Server** (in this example, ADserver) you configured previously. See [Examples and troubleshooting on page 332](#).
6. Select the **Users** or **Groups** or **Organizational Units** tab to select the users, groups, OU that you want to monitor.
7. Select **OK**.

To specify the collector agent for FSSO - CLI:

```
config user fssso
  edit "WinGroups"
    set ldap-server "ADserver"
    set password ENC
      G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EqT2J8zhOrbkJFDr0RmY3c4LaoXdsoBczA
      ldONmcGfthTxxwGsigzGpbJdC7lspFlQYtj
    set server "10.11.101.160"
  end
```

To create the FSSO_Internet-users user group - web-based manager:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	FSSO_Internet_users
Type	Fortinet Single Sign-On (FSSO)
Members	Engineering, Sales

To create the FSSO_Internet-users user group - CLI:

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
      CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

Creating the firewall user group

The non-FSSO users need a user group too. In this example, only two users are shown, but additional members can be added easily.

To create the firewall user group - web-based manager:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Internet_users
Type	Firewall
Members	User1, User2

To create the firewall user group - CLI:

```
config user group
  edit Internet_users
    set group-type firewall
    set member User1 User2
  end
```

Defining policy addresses

1. Go to **Policy & Objects > Addresses**.
2. Create the following addresses:

Address Name	Internal_net
---------------------	--------------

Type	Subnet
Subnet / IP Range	10.11.102.0/24
Interface	Port 3

Address Name	Windows_net
Type	Subnet
Subnet / IP Range	10.11.101.0/24
Interface	Port 2

Creating security policies

Two security policies are needed: one for firewall group who connect through port3 and one for FSSO group who connect through port2.

To create a security policy for FSSO authentication - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information:

Incoming Interface	Port2
Source Address	Windows_net
Source User(s)	FSSO_Internet_users
Outgoing Interface	Port1
Destination Address	all
Schedule	always
Service	ALL
NAT	ON
Security Profiles	Optionally, enable security profiles.

3. Select OK.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
edit 0
set srcintf port2
set dstintf port1
set srcaddr Windows_net
set dstaddr all
set action accept
```

```

set groups FSSO_Internet_users
set schedule always
set service ANY
set nat enable
end

```

To create a security policy for local user authentication - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information:

Incoming Interface	Port3
Source Address	Internal_net
Source User(s)	Internet_users
Outgoing Interface	Port1
Destination Address	all
Schedule	always
Service	ALL
NAT	ON
Security Profiles	Optionally, enable security profiles.

3. Select **OK**.

To create a security policy for local user authentication - CLI:

```

config firewall policy
edit 0
set srcintf port3
set dstintf port1
set srcaddr internal_net
set dstaddr all
set action accept
set schedule always
set groups Internet_users
set service ANY
set nat enable
end

```

LDAP dial-in using member-attribute example

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to set up a VPN connection simply based on an attribute that is set to TRUE, instead of based on their user group. In AD the "Allow Dialin" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

To accomplish this with a FortiGate unit, member-attribute must be set. This can only be accomplished through the CLI - the option is not available through the web-based manager.

Before configuring the FortiGate unit, ensure the AD server has the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to authenticate.

To configure user LDAP member-attribute settings - CLI:

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=fortilabanz,DC=com,DC=au"
    set type regular
    set username "fortigate@sample.com"
    set password *****
    set member-attr "msNPAllowDialin"
  next
end
```

To configure LDAP group settings - CLI:

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap"
        set group-name "TRUE"
      next
    end
  next
end
```

Once these settings are in place, users that are a member of the `ldap` user group will be able to authenticate.

To ensure your settings are correct, here is the sample output from a `diag debug` command that shows the authentication process.

When the "Allow Dial-in" attribute is set to "TRUE" the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the attribute is not set but it is expected, the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='FALSE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
```

```
fnbamd_auth_poll_ldap-Failed group matching
```

The only difference between these two outputs is the last line which is either passed or failed based on if the member-attribute is set to the expected value or not.

RADIUS SSO example

A common RADIUS SSO topology involves a medium sized company network of users connecting to the Internet through the FortiGate unit, and authenticating with a RADIUS server. RADIUS SSO authentication was selected because it is fast and relatively easy to configure.

This section includes:

- [Assumptions](#)
- [Topology](#)
- [Configuring RADIUS](#)
- [Configuring FortiGate regular and RADIUS SSO security policies](#)
- [Testing](#)

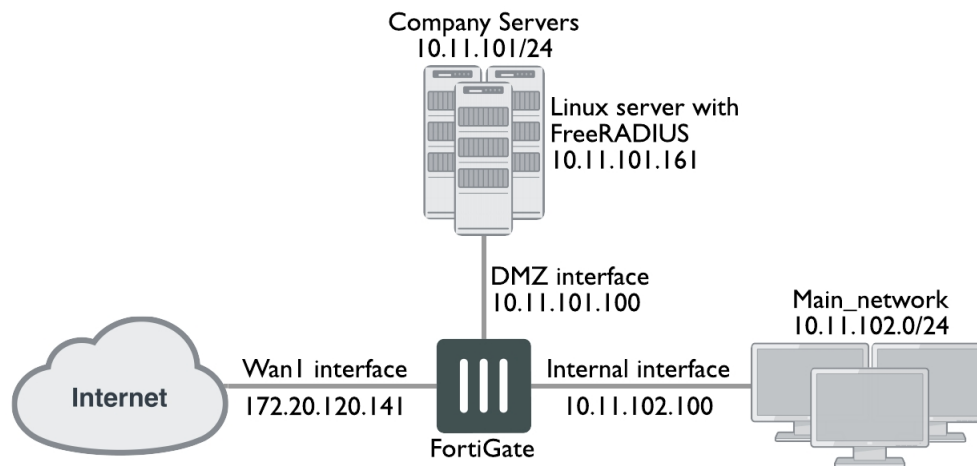

Assumptions

- VDOMs are not enabled.
- The admin super_admin administrator account will be used for all FortiGate unit configuration.
- Any other devices on the network do not affect the topology of this example, and therefore are not included.
- Anywhere settings are not described, they are assumed to be default values.
- A RADIUS server is installed on a server or FortiAuthenticator unit and uses default attributes.
- BGP is used for any dynamic routing.
- Authentication event logging under **Log & Report** has been configured.

Topology

Example.com has an office with 20 users on the internal network. These users need access to the Internet to do their jobs. The office network is protected by a FortiGate-60C unit with access to the Internet through the wan1 interface, the user network on the internal interface, and all the servers are on the DMZ interface. This includes an Ubuntu Linux server running FreeRADIUS. For this example only two users will be configured — Pat Lee with an account name `plee`, or `plee@example.com`, and Kelly Green with an account name `kgreen`, or `kgreen@example.com`.

RADIUS SSO topology

Configuring RADIUS

Configuring RADIUS includes configuring the RADIUS server such as FreeRADIUS, a radius client on user's computers, and configuring users in the system. For this example the two users will be Pat Lee, and Kelly Green. They belong to a group called `exampledotcom_employees`. When it is all configured, the RADIUS daemon needs to be started.

The users have a RADIUS client installed on their PCs that allows them to authenticate through the RADIUS server.

FreeRADIUS can be found on the freeradius.org website. For any problems installing FreeRADIUS, see the FreeRADIUS documentation.

Configuring FortiGate interfaces

Before configuring the RADIUS SSO security policy, configure FortiGate interfaces. This includes defining a DHCP server for the internal network as this type of network typically uses DHCP. The wan1 and dmz interfaces are assigned static IP addresses and do not need a DHCP server.

FortiGate interfaces used in this example

Interface	Subnet	Act as DHCP Server	Devices
wan1	172.20.120.141	No	Internet Service Provider
dmz	10.11.101.100	No	Servers, including RADIUS server
internal	10.11.102.100	Yes: x.x.x.110-.250	Internal user network

To configure FortiGate interfaces - web-based manager:

1. Go to **Network > Interfaces**.
2. Select wan1 to edit.

3. Enter the following information and select **OK**.

Alias	Internet
Addressing Mode	Manual
IP/Network Mask	172.20.120.141/255.255.255.0
Administrative Access	HTTPS, SSH
Enable DHCP Server	Not selected
Comments	Internet
Administrative Status	Up

4. Select dmz to edit.
5. Enter the following information and select **OK**.

Alias	Servers
Addressing Mode	Manual
IP/Network Mask	10.11.101.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING, SNMP
Enable DHCP Server	Not selected
Listen for RADIUS Accounting Messages	Select
Comments	Servers
Administrative Status	Up

6. Select internal to edit.
7. Enter the following information and select **OK**.

Alias	Internal network
Addressing Mode	Manual
IP/Network Mask	10.11.102.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING
Enable DHCP Server	Select
Address Range	10.11.102.110 - 10.11.102.250
Netmask	255.255.255.0

Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
Comments	Internal network
Administrative Status	Up

Configuring a RADIUS SSO agent on the FortiGate unit

To create a RADIUS SSO agent:

1. Go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Under **SSO/Identity**, select **RADIUS Single Sign-On Agent**.
3. Enter a name for the RSSO Agent.
4. Enable **Use RADIUS Shared Secret** and enter the RADIUS server's shared secret.
5. Enable **Send RADIUS Responses**.
6. Select **OK**.

Creating a RADIUS SSO user group

To define a local user group for RADIUS SSO:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

Configuring FortiGate regular and RADIUS SSO security policies

With the RADIUS server and FortiGate interfaces configured, security policies can be configured. This includes both RADIUS SSO and regular policies, as well as addresses and address groups. All policies require NAT to be enabled.

Security policies required for RADIUS SSO

Seq. No.	From -> To	Type	Schedule	Description
1	internal -> wan1	RADIUS SSO	business hours	Authenticate outgoing user traffic.
2	internal -> wan1	regular	always	Allow essential network services and VoIP.
3	dmz -> wan1	regular	always	Allow servers to access Internet.

Seq. No.	From -> To	Type	Schedule	Description
4	internal -> dmz	regular	always	Allow users to access servers.
5	any -> any	deny	always	Implicit policy denying all traffic that hasn't been matched.

The RADIUS SSO policy must be placed at the top of the policy list so it is matched first. The only exception to this is if you have a policy to deny access to a list of banned users. In this case, that policy must go at the top so the RADIUS SSO does not mistakenly match a banned user or IP address.

This section includes:

- [Schedules, address groups, and services groups](#)
- [Configuring regular security policies](#)
- [Configuring RADIUS SSO security policy](#)

Schedules, address groups, and services groups

This section lists the lists that need to be configured before security policies are created. Creating these lists is straight forward, so the essential information has been provided here but not step by step instructions. For more information on firewall related details, see

Schedules

Only one schedule needs to be configured — `business_hours`. This is a fairly standard Monday to Friday 8am to 5pm schedule, or whatever days and hours covers standard work hours at the company.

Address groups

The following address groups need to be configured before the security policies.

Address Group Name	Interface	Address range included
internal_network	internal	10.11.102.110 to 10.11.102.250
company_servers	dmz	10.11.101.110 to 10.11.101.250

Service groups

The following service groups need to be configured before the security policies. Note that the services listed are suggestions and may include more or less as required.

Service Group Name	Interface	Description of services to be included
essential_network_services	internal	Any network protocols required for normal network operation such as DNS, NTP, BGP.
essential_server_services	dmz	All the protocols required by the company servers such as BGP, HTTP, HTTPS, FTP, IMAP, POP3, SMTP, IKE, SQL, MYSQL, NTP, TRACEROUTE, SOCKs, and SNMP.
user_services	internal	Any protocols required by users HTTP, HTTP, FTP,

The following security policy configurations are basic and only include logging, and default AV and IPS.

Configuring regular security policies

Regular security policies allow or deny access for non-RADIUS SSO traffic. This is essential as there are network services—such as DNS, NTP, and FortiGuard—that require access to the Internet.

To configure regular security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**, and select **Create New**.
2. Enter the following information, and select **OK**.

Incoming Interface	Internal
Source Address	internal_network
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	essential_network_services
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	ON
Comments	Essential network services

3. Select **Create New**, enter the following information, and select **OK**.

Incoming Interface	dmz
Source Address	company_servers
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	essential_server_services
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	enable
Comments	Company servers accessing the Internet

4. Select **Create New**, enter the following information, and select **OK**.

Incoming Interface	Internal
Source Address	internal_network
Outgoing Interface	dmz
Destination Address	company_servers
Schedule	always
Service	all
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	enable
Comments	Access company servers

Configuring RADIUS SSO security policy

The RADIUS SSO policy allows access for members of specific RADIUS groups.

To configure RADIUS SSO security policy:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information:

Incoming Interface	Internal
Source Address	internal_network
Source User(s)	Select the user groups you created for RSSO.
Outgoing Interface	wan1
Destination Address	all
Schedule	business_hours
Service	ALL
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, Web Filter, IPS, and Email Filter. In each case, select the default profile.

4. Select **OK**.
5. To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.
6. Select **OK**.

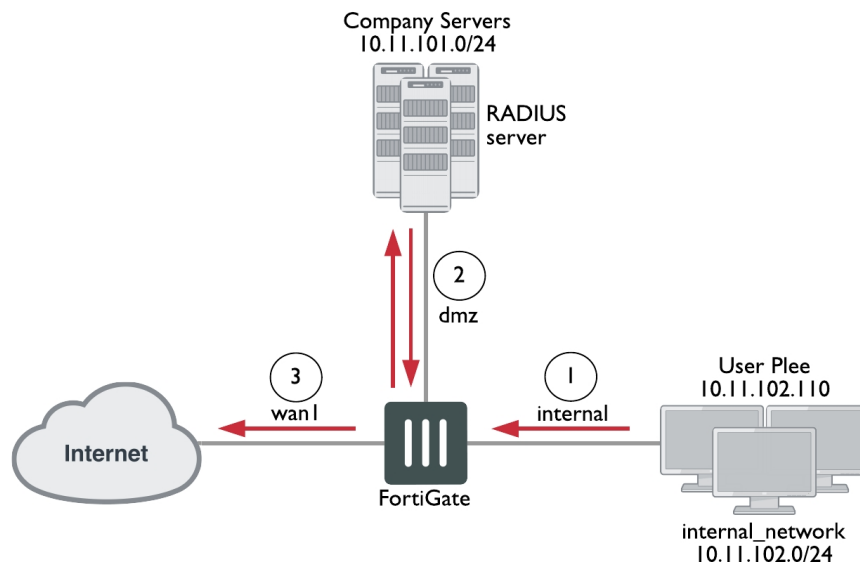

Testing

Once configured, a user only needs to log on to their PC using their RADIUS account. After that when they attempt to access an Internet website, the FortiGate unit will use their session information to get their RADIUS information. Once the user is verified, they are allowed access to the website.

To test the configuration perform the following steps:

1. Have user 'plee' logon to their PC, and try to access an Internet website.
2. The FortiGate unit will contact the RADIUS server for user plee's information.
Once confirmed, plee will have access to the website.
Each step generates log entries that enable you to verify that each step was successful.
3. If a step is unsuccessful, confirm that your configuration is correct.

RADIUS SSO test

Troubleshooting

In the web-based manager, a good tool for troubleshooting is the packet counter column on the security policy page at **Policy & Objects > IPv4 Policy**. This column displays the number of packets that have passed through this security policy. Its value when you are troubleshooting is that when you are testing your configuration (end to end connectivity, user authentication, policy use) watching the packet count for an increase confirms any other methods you may be using for troubleshooting. It provides the key of which policy is allowing the traffic, useful information if you expect a user to require authentication and it never happens.

This section addresses how to get more information from the CLI about users and user authentication attempts to help troubleshoot failed authentication attempts.

```
diag firewall iprope list
```

Shows the IP that the computer connected from. This is useful to confirm authorization and VPN settings.

```
diag firewall iprope clear
```

Clear all authorized users from the current list. Useful to force users to re-authenticate after system or group changes. However, this command may easily result in many users having to re-authenticate, so use carefully.

```
diag rso query ip
```

```
diag rso query rso-key
```

Queries the RSSO database.

For more information on troubleshooting specific features, go to that section of this document. Most sections have troubleshooting information at the end of the section. In addition to that information, see the [FortiOS Handbook Troubleshooting](#) guide for general troubleshooting information.

Chapter 4 - Best Practices

Introduction

This FortiGate Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGate units in a customer environment. It is updated periodically as new issues are identified.

General considerations

1. For security purposes, NAT mode is preferred because all of the internal or DMZ networks can have secure private addresses. NAT mode policies use network address translation to hide the addresses in a more secure zone from users in a less secure zone.
2. Use virtual domains (VDOMs) to group related interfaces or VLAN subinterfaces. Using VDOMs will partition networks and create added security by limiting the scope of threats.
3. Use Transparent mode when a network is complex and does not allow for changes in the IP addressing scheme.

Customer service and technical support

For antivirus and IPS updates, firmware updates, updated product documentation, technical support information, and other resources, visit the Fortinet Support website at <https://support.fortinet.com>.

You can also register Fortinet products and service contracts and change your registration information at any time. You can also find a guide to Fortinet's Support services from: [How to work with Fortinet Support](#).

When requesting technical support, for optimum results you should provide as much of the following information as possible:

- Your name, and your company's name and location
- Your email address and/or telephone number
- Your support contract number (if applicable)
- The product name and model number
- The product serial number (if applicable)
- The software or firmware version number
- A detailed description of the problem

Fortinet Knowledge Base

The most recent Fortinet technical documentation is available from the Fortinet Knowledge Base. The knowledge base contains short how-to articles, FAQs, technical notes, product and feature guides, and much more. Visit the Fortinet Knowledge Base at <http://kb.fortinet.com>.

Comments on Fortinet technical documentation

Please send information about any errors or omissions in this document, or any Fortinet technical documentation, to techdoc@fortinet.com.

System and performance

By implementing the following best practices for system and performance, you will ensure maximum efficiency of your FortiGate device. Be sure to read everything carefully, particularly the section that concerns shutting down the FortiGate system, in order to avoid potential hardware issues.

Performance

- Disable any management features you do not need. If you don't need SSH or SNMP, disable them. SSH also provides another possibility for would-be hackers to infiltrate your FortiGate unit.
- Put the most used firewall rules to the top of the interface list.
- Log only necessary traffic. The writing of logs, especially if to an internal hard disk, slows down performance.
- Enable only the required application inspections.
- Keep alert systems to a minimum. If you send logs to a syslog server, you may not need SNMP or email alerts, making for redundant processing.
- Establish scheduled FortiGuard updates at a reasonable rate. Daily updates occurring every 4-5 hours are sufficient for most situations. In more heavy-traffic situations, schedule updates for the evening when more bandwidth can be available.
- Keep security profiles to a minimum. If you do not need a profile on a firewall rule, do not include it.
- Keep VDOMs to a minimum. On low-end FortiGate units, avoid using them if possible.
- Avoid traffic shaping if you need maximum performance. Traffic shaping, by definition, slows down traffic.

Shutting down

Always shut down the FortiGate operating system properly before turning off the power switch to avoid potentially catastrophic hardware problems.

To power off the FortiGate unit - web-based manager:

1. Go to **Dashboard**.
2. In the **System Resources** widget, select **Shutdown**.

To power off the FortiGate unit – CLI:

```
execute shutdown
```

Once this has been done, you can safely turn off the power switch or disconnect the power cables from the power supply.

Migration

Network administrators are often reluctant to change firewall vendors due to the perception that the migration process is difficult. Indeed, there is no point hiding the fact that moving to a new vendor requires careful consideration. But concern over the potential pain of migration should not stand in the way of adopting new security technologies. The purpose of this chapter is to describe the best practices for performing such migrations and ultimately to ease the migration process itself.

Information gathering

It is always best practice to perform a full network audit prior to any migration. This should include:

- Full back up of all security systems (including switches, routers) in case a back-out needs to be performed.
- Physical and logical network diagram with visual audit

Understanding exactly where cables run in the network and verifying they are all correctly labeled is essential to avoid mistakes and unnecessary downtime during the upgrade. Don't overlook simple things such as:

- Do I have enough spare interfaces on my switches?
- Do I have the right fiber (single/multi mode) and right connectors (LC, FC, MTRJ, SC, ST)?
- Do I have spare cables? (in the heat of the moment, it is a simple mistake to break an RJ-45 connector or damage a fiber)
- Do I have space in the rack for the new equipment?
- Do I have enough power sockets?

No matter how securely a FortiGate is configured in the network, it cannot help if it has been bypassed; visually checking where the device sits in the network in relation to other devices will ensure you are maintaining security and verify the network diagram is 'as built'. Details of all networks including subnet masks should be documented at this point to ensure that the replacement device is configured with the correct information.

Object and policy migration

Whilst we have suggested some level of manual review is included in the policy migration, it can be useful to be able to automatically migrate simply between another vendor's format and the FortiGate format. The FortiGate policy format is text based and can easily be cut and pasted into from other vendor formats however, responding to the high customer demand to migrate away from other vendors, Fortinet have released an automatic configuration migration tool at <http://convert.fortinet.com> to simplify this process. Supporting Cisco ACLs, PIX, ASA, Check Point, and Juniper, the Converter can securely upload and convert the policy into the Fortinet format.

Testing and validation

This is an important process and should be tested offline first wherever possible i.e. configure the policy in the lab or on a test network and verify that the required access permissions are being implemented. To really test the solution out, the FortiGate can be implemented on the live network with a different gateway IP and the selected user pointed to the new gateway. This allows a staged approach to migrating the new platform into the network ensuring that the process does not interrupt day to day operations.

Going live and obtaining feedback

If testing and validation is successful at this point, you can migrate to the new firewall either by switching IP's and removing the old devices or by changing the default gateway in DHCP. Once the firewall is in place, acceptance testing will of course need to be carried out and an iterative process of tuning undertaken to finalize the configuration.

Adding new services

The Fortinet solution will have a plethora of additional features compared to your previous vendor and it is very tempting to start switching them on but it is a good idea to wait and validate the new firewall as was previously configured before adding new functions as this simplifies testing and problem diagnosis. Finally complete the migration (don't forget about the Plan Do Check Act Cycle) by adding any new services that were requested and learn about the multiple features you have available with the FortiGate appliance.

Environmental specifications

Keep the following environmental specifications in mind when installing and setting up your FortiGate unit.

- Operating temperature: 32 to 104°F (0 to 40°C). Temperatures may vary, depending on the FortiGate model.
- If you install the FortiGate unit in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient temperature.
Therefore, make sure to install the equipment in an environment compatible with the manufacturer's maximum rated ambient temperature.
- Storage temperature: -13 to 158°F (-25 to 70°C). Temperatures may vary, depending on the FortiGate model.
- Humidity: 5 to 90% non-condensing.
- Air flow - For rack installation, make sure that the amount of air flow required for safe operation of the equipment is not compromised.
- For free-standing installation, make sure that the appliance has at least 1.5 in. (3.75 cm) of clearance on each side to allow for adequate air flow and cooling.

Depending on your device, the FortiGate may generate, use, and even radiate radio frequency energy and, if not installed and used in accordance with the instructions, may cause harmful interference to radio communications. However, there is no guarantee that interference will not occur in a particular installation. If the equipment does cause harmful interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient or relocate the receiving antenna.
- Increase the separation between the equipment and receiver.
- Connect the equipment into an outlet on a circuit different from that to which the receiver is connected.
- Consult the dealer or an experienced radio/TV technician for help.

Explosion is a serious risk if the battery is replaced by an incorrect type. Dispose of used batteries according to the instructions. To reduce the risk of fire, use only No. 26 AWG or larger UL Listed or CSA Certified Telecommunication Line Cord.

Grounding

- Ensure the FortiGate unit is connected and properly grounded to a lightning and surge protector. WAN or LAN connections that enter the premises from outside the building should be connected to an Ethernet CAT5 (10/100 Mb/s) surge protector.
- Shielded Twisted Pair (STP) Ethernet cables should be used whenever possible rather than Unshielded Twisted Pair (UTP).
- Do not connect or disconnect cables during lightning activity to avoid damage to the FortiGate unit or personal injury.

Rack mounting

- **Elevated Operating Ambient** - If installed in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient.
Therefore, consideration should be given to installing the equipment in an environment compatible with the maximum ambient temperature (Tmax) specified by the manufacturer.

- **Reduced Air Flow** - Installation of the equipment in a rack should be such that the amount of air flow required for safe operation of the equipment is not compromised.
- **Mechanical Loading** - Mounting of the equipment in the rack should be such that a hazardous condition is not achieved due to uneven mechanical loading.
- **Circuit Overloading** - Consideration should be given to the connection of the equipment to the supply circuit and the effect that overloading of the circuits might have on overcurrent protection and supply wiring. Appropriate consideration of equipment nameplate ratings should be used when addressing this concern.
- **Reliable Earthing** - Reliable earthing of rack-mounted equipment should be maintained.

Particular attention should be given to supply connections other than direct connections to the branch circuit (e.g. use of power strips).

Firmware

Firmware upgrading and downgrading sounds pretty simple, anyone can do it, right? The mark of a professional is not that they can do something correctly, or even do it correctly over and over again. A professional works in such a way that, if anything goes wrong they are prepared and able to quickly get things back to normal. Firmware updates can go wrong just like anything else. So a real professional does things in a way that minimizes their risk and follows some best practices, as listed below.

Firmware change management

Consider the following five points when performing firmware upgrades, not only in FortiOS but in general. This applies to pretty much any change you have to do in a production environment.

Understanding the new version first

Before attempting any changes in production, first make sure you set up a laboratory where you can freely play with the new features, and understand them with enough time and no pressure. Read the Release Notes, Manuals, and other documentation like presentations, videos, or podcasts about the new version.

You are ready to explain the need for an upgrade once you understand:

- The differences and the enhancements between the new version and the previous version(s).
- The impact of the upgrade on customers and the users of the operating platform.
- The known limitations that might affect your environment.
- The potential risks when performing the upgrade.
- The licensing changes that may apply.

Never attempt to upgrade to a version you don't fully understand (both on features and known limitations), and on which you have no operational experience.

Have a valid reason to upgrade

The reason can NOT be "Because I want to have the latest version". The reason has to be explained in terms of business, technical, and/or operational improvement.

Affirmative answers to the following questions are valid reasons to upgrade:

- Does the new version have a feature that helps to ensure compliance?
- Does the new version have an enhancement that allows 40% decrease (40% improvement) on the time to perform a certain operation?
- Does the new feature correct a known defect/bug found on a previous version that affects the company business/operations?
- Will the new version allow your organization to deploy new services that will help to gain new customers or increase loyalty of existing ones?
- Is the vendor cutting support for the version your organization is currently using?

If the best reason to upgrade is “Because the new features seem to be cool” or “Because I want to have the latest version”, a little more understanding and planning may be necessary.

Prepare an upgrade plan

If you choose to upgrade because you found a valid reason to do so, make sure you create a plan that covers business, technical, and operational aspects of the upgrade:

Business:

Proper planning and justification for an upgrade should be proportional to how critical the system is to the business.

- Make sure you can clearly articulate the benefits of the upgrade in business terms (time, money, and efficiency).
- Understand the business processes that will be affected by the change.
- Make sure the upgrade maintenance window is not close to a business-critical process (such as quarterly or monthly business closure).
- Obtain executive and operational approval for the maintenance window. The approval must come from the owners of ALL the systems/information affected by the upgrade, not only from those that own the system being upgraded. The approval must be done in a formal (written or e-mail) form.

Technical and operational:

- Re-read the Release Notes for the technology you are upgrading. Supported hardware models, upgrade paths, and known limitations should be clearly understood.
- Make sure your upgrade maintenance window does not overlap with any other maintenance window on your infrastructure.
- If you have any premium support offer (such as TAM, Premium Support), do a capacity planning exercise to ensure the new firmware/software version does not take more hardware resources than you currently have.
- Create a backup, whether or not you have scheduled backups. Create a new fresh backup.
- Obtain offline copies of both the currently installed firmware and the new version.
- Create a list of systems with inter-dependencies to the system you are upgrading. For example, if you are upgrading a FortiGate; understand the impact on any FortiAP, FortiAuthenticator, FortiToken, FortiManager, or FortiAnalyzer you have on your environment.
- Ensure you have a list of adjacent devices to the upgrading platform and have administrative access to them, just in case you need to do some troubleshooting. Are you upgrading FortiWeb? Make sure you can administratively access the Web Applications. Are you upgrading a FortiGate? Make sure you can administratively access the surrounding switches and routers.
- Have a step-by-step plan on how to perform and test the upgrade. You want to make sure you think of the worst situation before it happens, and have predefined courses of action, instead of thinking under pressure when something already went wrong.
- Define a set of tests (that include critical business applications that should be working) to make sure the upgrade went fine. If any test does not go well, define which ones mandate a rollback and which ones can be tolerated for further troubleshooting. This set of tests should be run before and after the upgrade to compare results, and they should be the same.
- Define a clear rollback plan. If something goes wrong with the upgrade or the tests, the rollback plan will help you get your environment back to a known and operational status. The plan must clearly state the conditions under which the rollback will be started.

- Declare configuration freezes. A little bit before and after the upgrade. The idea is to reduce the amount of variables to take into consideration if something goes wrong.
- Perform a “Quality Assurance” upgrade. Grab a copy of the production configuration, load it on a non-production box and execute the upgrade there to see if there are any issues on the process. Then adjust your plan according to the results you obtained.
- Have a list of information elements to be gathered if something goes wrong. This ensures that, even if the upgrade fails, you will collect enough information so you can troubleshoot the issue without needing to repeat the problem. Get help from Fortinet Support if you need to check what else could be missing on your list.
- Define a test monitoring period after the change was completed. Even if the upgrade went smoothly, something could still go wrong. Make sure you monitor the upgraded system for at least one business cycle. Business cycles may be a week, a month, or a quarter, depending on your organization’s business priorities.

Execute the upgrade plan

Execution of an upgrade is just as key as planning.

Once you are performing the upgrade, the pressure will rise and stress might peak. This is why you should stick to the plan you created with a cool head.

Resist the temptation to take decisions while performing the upgrade, as your judgment will be clouded by the stress of the moment, even if a new decision seems to be “obvious” at such time. If your plan says you should rollback, then execute the rollback despite the potential “We-can-fix-this-very-quickly” mentality.

While performing the upgrade, make sure all the involved components are permanently monitored before, during, and after the upgrade, either via monitoring systems, SNMP alerts, or at least with tools like a ping. Critical resources like CPU, memory, network, and/or disk utilization must also be constantly monitored.

To avoid misunderstandings, when performing the tests for each critical application defined on the planning, make sure there are formal notifications on the results for each user area, service, system, and/or application tested.

Regardless if you have to rollback or not, if a problem occurs, make sure you gather as much information about the problem as possible, so you can later place a Support ticket to find a solution.

Last but not least, document the upgrade:

- Enable your terminal emulation program to leave trace of all the commands executed and all the output generated. If you are performing steps via GUI, consider using a video capture tool to document it.
- Document any command or change performed over the adjacent/interdependent systems. Make sure they are acknowledged by the relevant administrators
- Document any deviations performed over the upgrade plan. This is planned-versus-actual.

Learn more about change management

Change Management and Change Control are huge knowledge areas in the field of Information Systems and Computer/Network Security.

This document is by no means a comprehensive list on what you should do when performing an upgrade, with either Fortinet or any other technology. It is merely a list of important things you should take into consideration when performing upgrades which are the result of years of experience dealing with changes on critical environments, as it is common that security devices are protecting critical applications and processes.

There are vast resources on the topic: books, public white papers, blog entries, etc. If you search the Internet for the “Change Control Best Practices” or “Change Management Best Practices” you will get many interesting documents.

Changes on production IT infrastructure are critical to the business. Make sure they play in your favor and not against you.

Performing a firmware upgrade

Upgrading a firewall is something that should be compared to upgrading the operating system on your computer. It's not to be taken lightly! You want to make sure everything is backed up and you have some options available if things go awry. Assuming it all seems to work you also want a list of things to do in order to confirm everything is working properly. Finally, you need enough time to do it. All really simple stuff, but what does this mean in relation to upgrading your FortiGate? It means, you follow these simple steps:

- 1. Backup and store old configuration (full configuration backup from CLI).**

Digging into this a little, step 1 is easy to understand. Do a full backup of your old configuration. This is all part of your disaster recovery plan. If the upgrade fails in some way you need to make sure you can get the Firewall back up and running. The best way to do this is to get it back to a state where you know what the behavior was. For more information, refer to ["Performing a configuration backup" on page 359](#).

- 2. Have copy of old firmware available.**

Step 2, is also part of your disaster recovery. If the upgrade fails you might be able to switch the active partition. But as a Professional, you need to be prepared for the worst case scenario where you can't do that. Which means you'll need your old firmware.

- 3. Have disaster recovery option on standby – especially if remote.**

Step 3, is your plan for what to do in the event of a critical failure. As we're talking FortiGate this means that your firewall doesn't come back after the upgrade. What this means is that you need to be able to get to the console port in order to find out why. Maybe it's DHCP and the IP changed, maybe the OS is corrupt, who knows? Get to the console and find out.

There could be a simple fix. If there's not, then be prepared for a format and TFTP reload.

- 4. Read the release notes, including the upgrade path and bug information.**

Step 4, READ THE RELEASE NOTES. They contain all kinds of information, known bugs, fixed bugs even upgrade issues like lost configuration settings. Not all upgrade information is ever contained in any products release notes. That does not mean they are devoid of good/useful information. Read them, digest them, then a few days later read them again.

- 5. Double check everything.**

Step 5, do a double check of everything. Is your TFTP server working, does your console connection function, is there anything in the release notes that could impact your upgrade procedure, do you have your configuration backed up? Make sure you've done everything.

- 6. Upgrade.**

Step 6, do the upgrade. Doing an upgrade doesn't take very long, a few minutes (less a lot of times) but make sure you schedule enough time for it. At the end of the day an upgrade can succeed or fail. If it succeeds you want some time to check/confirm that any important features you have are working (VPNs etc). If it fails you'll need time to sort things out.

Performing a firmware downgrade

Just like upgrading, you need to make sure it's done properly. While similar, the steps are somewhat different since there are other pitfalls in this case.

- 1. Locate pre-upgrade configuration file.**

Step 1 is very important. This is why, when you upgrade you make a backup of your old configuration and save it. If you don't, then you'll need to rebuild manually.

- 2. Have copy of old firmware available.**

Step 2 is fairly obvious. Even with devices that have multiple partitions and your downgrade process is simply going to be to switch the active partition, this could go wrong. In which case, you may be without Internet access. A professional has a plan for when things go wrong.

- 3. Have disaster recovery option on standby – especially if remote.**

Step 3 is no different from before. Hopefully you don't need to format the unit, but be prepared for that, just in case.

- 4. Read the release notes – is a downgrade possible, or necessary?**

Step 4, once again, is to READ THE RELEASE NOTES. In this case, you will need to do this for the version you are on, and the version you are downgrading too, and everything in between (if you are going back multiple major releases or patches). Maybe the OS switched from 32 to 64 bits somewhere between the two firmware releases. In order to make sure you don't get nailed by something like that you need to check the upgrade and downgrade information in every major release and patch, as it may have a direct impact on your options.

- 5. Double check everything.**

- 6. Downgrade – all settings, except those needed for access, are lost.**

Step 5 and 6 are the same as before. Double check everything, then downgrade.

- 7. Restore pre-upgrade configuration.**

Step 7 is new. Obviously most settings are lost when you downgrade so in order to get back up and running you will need to restore your old configuration file.

Performing a configuration backup

Once you configure the FortiGate unit and it is working correctly, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate unit to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it.

It is also recommended that once any further changes are made that you backup the configuration immediately, to ensure you have the most current configuration available. Also, ensure you backup the configuration before upgrading the FortiGate unit's firmware. Should anything happen during the upgrade that changes the configuration, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP and TFTP site. The latter two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate unit or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

To back up the FortiGate configuration - web-based manager:

1. Go to **Dashboard**.
2. On the **System Information** widget, select **Backup** next to **System Configuration**.
3. Select to backup to your **Local PC** or to a **USB Disk**.
The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
4. If VDOMs are enabled, select to backup the entire FortiGate configuration (**Full Config**) or only a specific VDOM configuration (**VDOM Config**).
5. If backing up a VDOM configuration, select the VDOM name from the list.
6. Select **Encrypt configuration file**.
Encryption must be enabled on the backup file to back up VPN certificates.
7. Enter a password and enter it again to confirm it. You will need this password to restore the file.
8. Select **Backup**.
9. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

To back up the FortiGate configuration - CLI:

```
execute backup config management-station <comment>
```

... or ...

```
execute backup config usb <backup_filename> [<backup_password>]
```

... or for FTP (note that port number, username are optional depending on the FTP site)...

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]  
[<password>]
```

... or for TFTP ...

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom  
edit <vdom_name>
```

Backing up a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate unit as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for an administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate unit. SCP is enabled using the CLI commands:

```
config system global  
set admin-scp enable  
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global  
set admin-scp enable  
end
```

```
config vdom
  edit <vdom_name>
```

Security Profiles (AV, Web Filtering etc.)

Infection can come from many sources and have many different effects. Because of this, there is no single means to effectively protect your network. Instead, you can best protect your network with the various UTM tools your FortiGate unit offers.

Firewall

- Be careful when disabling or deleting firewall settings. Changes that you make to the firewall configuration using the GUI or CLI are saved and activated immediately.
- Arrange firewall policies in the policy list from more specific to more general. The firewall searches for a matching policy starting from the top of the policy list and working down. For example, a very general policy matches all connection attempts. When you create exceptions to a general policy, you must add them to the policy list above the general policy.
- Avoid using the All selection for the source and destination addresses. Use addresses or address groups.
- If you remove all policies from the firewall, there are no policy matches and all connections are dropped.
- If possible, avoid port ranges on services for security reasons.
- The settings for a firewall policy should be as specific as possible. Do not use 0.0.0.0 as an address. Do not use Any as a service. Use subnets or specific IP addresses for source and destination addresses and use individual services or service groups.
- Use a 32-bit subnet mask when creating a single host address (for example, 255.255.255.255).
- Use logging on a policy only when necessary and be aware of the performance impact. For example, you may want to log all dropped connections but can choose to use this sparingly by sampling traffic data rather than have it continually storing log information you may not use.
- It is possible to use security policies based on 'any' interface. However, for better granularity and stricter security, explicit interfaces are recommended.
- Use the comment field to input management data, for example: who requested the rule, who authorized it, etc.
- Avoid FQDN addresses if possible, unless they are internal. It can cause a performance impact on DNS queries and security impact from DNS spoofing.
- For non vlan interfaces, use zones (even if you have only one single interface for members) to allow:
 - An explicit name of the interface to use in security policies ('internal' is more explicit than 'port10').
 - A split between the physical port and its function to allow port remapping (for instance moving from a 1G interface to a 10G interface) or to facilitate configuration translation, as performed during hardware upgrades.

Security

- Use NTP to synchronize time on the FortiGate and the core network systems, such as email servers, web servers, and logging services.
- Enable log rules to match corporate policy. For example, log administration authentication events and access to systems from untrusted interfaces.
- Minimize adhoc changes to live systems, if possible, to minimize interruptions to the network. When not possible, create backup configurations and implement sound audit systems using FortiAnalyzer and FortiManager.
- If you only need to allow access to a system on a specific port, limit the access by creating the strictest rule possible.

Authentication

- You must add a valid user group to activate the Authentication check box on the firewall policy configuration page.
- Users can authenticate with the firewall using HTTP or FTP. For users to be able to authenticate, you must add an HTTP or FTP policy that is configured for authentication.

Antivirus

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure you receive antivirus signature updates as soon as they are available.
- To ensure that all AV push updates occur, ensure you have an AV profile enabled in a security policy.
- Enable only the protocols you need to scan. If you have antivirus scans occurring on the SMTP server, or use FortiMail, it is redundant to have scanning occur on the FortiGate unit as well.
- Reduce the maximum file size to be scanned. Viruses usually travel in small files of around 1 to 2 megabytes.
- Do not quarantine files unless you regularly monitor and review them. This is otherwise a waste of space and impacts performance.
- Examine antivirus reports and log messages periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.

Antispam

- If possible use, a FortiMail unit. The antispam engines are more robust.
- Use fast DNS servers.
- Use specific security profiles for the rule that will use antispam.
- DNS checks may cause false positive with HELO DNS lookup.
- Content analysis (banned words) may impose performance overhead.

Intrusion Prevention System (IPS)

Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions. Refer to the following list of best practices regarding IPS.

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive IPS signature updates as soon as they are available.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Create and use security profiles with specific signatures and anomalies you need per-interface and per-rule.
- Do not use predefined or generic profiles. While these profiles are convenient to supply immediate protection, you should create profiles to suit your network environment.

- If you do use the default profiles, reduce the IPS signatures/anomalies enabled in the profile to conserve processing time and memory.
- If you are going to enable anomalies, make sure you tune thresholds according to your environment.
- If you need protection, but not audit information, disable the logging option.
- Tune the IP-protocol parameter accordingly.

Blocking Skype using CLI options for improved detection

If you want to identify or block Skype sessions, use the following CLI command with your FortiGate's public IP address to improve detection (FortiOS 4.3.12+ and 5.0.2+):

```
config ips global
    set skype-client-public-ipaddr 198.51.100.0,203.0.113.0
end
```

Note that the above syntax is configured using multiple public IP addresses, where a single public IP address may suffice depending on your network configuration.

Email filter

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine.

- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to the FortiGuard AntiSpam Service.

URL filtering

Best practices for URL filtering can be divided into four categories: flow-based versus proxy based filtering; local category/rating feature; URL filter 'Exempt' action; and Deep Scan.

Flow-based versus proxy-based

Try to avoid mixing flow-based and proxy-based features in the same profile if you are not using IPS or Application Control.

Local category/rating feature

Local categories and local rating features consume a large amount of CPU resources, so use these features as little as possible. It is better to use Local categories instead of using the 'override' feature, since the 'override' feature is more complicated and more difficult to troubleshoot.

URL filter 'Exempt' action

When using the URL filter 'Exempt' option, webfilter, antivirus and dlp scans are bypassed by default, so use this option only for trusted sites.

Configuration notes: You need to configure 'Exempt' actions in the URL filter if you want to bypass the FortiGuard Web Filter. You can configure which particular inspection(s) you want to bypass using the `set exempt` command in `config webfilter urlfilter`.

Deep Scan

The 'Deep Scan' feature is much heavier on resources than 'HTTPS URL Scan Only'. Deep Scan is much more accurate, since many sites (such as various Google applications) cannot be scanned separately without deep scanning enabled.

Note: If you configure Deep Scan in the SSL profile and then configure 'Enable HTTPS URL Scan Only' in the web filter profile, then Deep Scan is not performed.

Web filtering

FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous

Patch management

When vulnerabilities are discovered in software, the software vendors release updates that fix these problems. Keeping your software and operating system up-to-date is a vital step to prevent infection and defend against attacks.

- Follow the latest advisories and reports on the FortiGuard webpage.
- Apply updates to all software as the updates become available.
- FortiGuard Vulnerability Management can help identify security weaknesses in your network. This subscription service is available through FortiScan and FortiAnalyzer units.
- Apply firmware updates to your FortiGate unit as they are released.
- Subscribe to FortiGuard AntiVirus and IPS services, so that AntiVirus and IPS scanning engines are automatically updated when new version are released.

Policy configuration

Configuring the FortiGate unit with an 'allow all' traffic policy is very undesirable. While this does greatly simplify the configuration, it is less secure. As a security measure, it is best practice for the policy rulebase to 'deny' by default, and not the other way around.

Policy configuration changes

On a heavy-loaded system, plan configuration changes during low usage periods in order to minimize impact on CPU usage and established sessions. In this scenario, it is considered a best practice to de-accelerate the hardware-accelerated sessions.

You can configure de-accelerated behaviour on hardware-accelerated sessions using CLI commands to control how the processor manages policy configuration changes. The following CLI commands are to be used:

```
config system settings
    set firewall-session-dirty { check-all | check-new | check-policy-option }
end
```

where you want the following to be true:

<code>check-all</code>	CPU flushes all current sessions and re-evaluates them. This is the default option.
<code>check-new</code>	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
<code>check-policy-option</code>	Use the option selected in the <code>firewall-session-dirty</code> field of the firewall policy (<code>check-all</code> or <code>check-new</code> , as above, but per policy).

Policy whitelisting

- Allow only the necessary inbound and outbound traffic.
- If possible, limit traffic to specific addresses or subnets. This allows the FortiGate unit to drop traffic to and from unexpected addresses.

IPS and DoS policies

- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to Block.
- DoS attacks are launched against vulnerabilities. Maintain a FortiGuard IPS subscription to ensure your FortiGate unit automatically receives new and updated IPS signatures as they are released.
- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received. The key is to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, but your network may require very different values. One way to find the correct values for your environment is to set the action to Pass and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

Networking

When configuring your network, ensure that there is no 'back door' access to the protected network. For example, if there is a wireless access point, it must be appropriately protected with password and encryption.

Be sure to also maintain an up-to-date network diagram which includes IP addressing, cabling, and network elements.

Routing configuration

- Always configure a default route.
- Add blackhole routes for subnets reachable using VPN tunnels. This ensures that if a VPN tunnel goes down, traffic is not mistakenly routed to the Internet unencrypted.

Policy routing

Keep the number of policy routes to a minimum to optimize performance in route lookup and to simplify troubleshooting.

Dynamic routing

- Select a Router ID that matches an IP assigned to an interface. This avoids the likelihood of having two devices with the same router ID.
- For routing over an IPsec tunnel, assign IP addresses to both ends of the tunnel.

Advanced routing

Use the following best practices for advanced routing when dealing with Border Gateway Protocol (BGP) and Open Shortest Path First (OSPF).

Border Gateway Protocol (BGP)

If you are using BGP, it is recommended that you enable soft-reconfiguration. This has two benefits:

- It allows you to perform 'soft clear' of peers after a change is made to a BGP policy.
- It provides greater visibility into the specific prefixes learned from each neighbor.

Leave soft-reconfiguration disabled if your FortiGate does not have much unused memory. Soft-reconfiguration requires keeping separate copies of prefixes received and advertised, in addition to the local BGP database.

Open Shortest Path First (OSPF)

- Avoid use of passive interfaces wherever possible.
- Avoid use of virtual links to connect areas. All areas should be designed to connect directly to the backbone area.
- Ensure that all backbone routers have a minimum of two peering connections to other backbone neighbors.
- An entire OSPF domain should be under common administration.

Network Address Translation (NAT)

- Beware of misconfiguring the IP Pool range. Double-check the start and end IPs of each IP pool. The IP pool should not overlap with addresses assigned to FortiGate interfaces or to any hosts on directly connected networks.
- If you have internal and external users accessing the same servers, use split DNS to offer an internal IP to internal users so that they don't have to use the external-facing VIP.

Configuring NAT

Do not enable NAT for inbound traffic unless it is required by an application. If, for example, NAT is enabled for inbound SMTP traffic, the SMTP server might act as an open relay.

Transparent Mode

- Do not connect two ports to the same VLAN on a switch or to the same hub. Some Layer 2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN.
- If you operate multiple VLANs on your FortiGate unit, assign each VLAN id to its own forwarding domain to ensure that the scope of the broadcast does not extend beyond the VLAN it originated in.

To protect against Layer 2 loops:

- Enable `stpforward` on all interfaces.
- Use separate VDOMs for production traffic (TP mode VDOM) and management traffic (NAT/Route mode VDOM).
- Only place those interfaces used for production in the TP mode VDOM. Place all other interfaces in the NAT/Route mode VDOM. This protects against potential Layer 2 loops.

Using virtual IPs (VIPs)

- Use the external IP of 0.0.0.0 when creating a VIP for a FortiGate unit where the external interface IP address is dynamically assigned.
- Be sure to select the correct external interface when creating a new virtual IP (VIP). The external interface should be set to the interface at which the FortiGate unit receives connection requests from external networks.

FGCP high availability

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection.
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance).
- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.
- If you need to enable session pickup, consider enabling `session-pickup-delay` to improve performance by reducing the number of sessions that are synchronized. See [Improving session synchronization performance on page 1](#).
- Consider using the `session-sync-dev` option to move session synchronization traffic off the HA heartbeat link to one or more dedicated session synchronization interfaces. See [Improving session synchronization performance on page 1](#).
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit.
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- Configure at least two heartbeat interfaces and set these interfaces to have different priorities.
- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.
 - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See [Enabling or disabling HA heartbeat encryption and authentication on page 1529](#).
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NP4 or NP6 processor to avoid NP4 or NP6-related problems from affecting heartbeat traffic.
- Where possible, the heartbeat interfaces should not be connected to an NP4 or NP6 processor that is also processing network traffic.
- Where possible, each heartbeat interface should be connected to a different NP4 or NP6 processor.
- Any FortiGate interface can be used as a heartbeat interface including 10/100/1000Base-T, SFP, QSFP fiber and copper, and so on. If you set up two or more interfaces as heartbeat interfaces each interface can be a different type and speed.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See [Remote link failover on page 1556](#).

WAN Optimization

WAN Optimization features require significant memory resources and generate a high amount of I/O on disk. Before enabling WAN Optimization, ensure that the memory usage is not too high. If possible, avoid other disk-intensive features such as heavy traffic logging on the same disk as the one configured for WAN Optimization needs.

In general, it is preferable to enable the Transparent Mode checkbox and ensure that routing between the two endpoints is acceptable. Some protocols may not work well without enabling Transparent Mode.

Other best practices for utilizing the WAN Optimization feature follow.

Sharing the WAN Opt. tunnel for traffic of the same nature

WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic (such as CIFS traffic from different servers). However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel.

Ordering WAN Opt. rules appropriately

- Precise, port specific WAN Optimization rules should be at the top of the list.
- Generic rules, such as overall TCP, should be at the bottom of the list.

Avoiding mixing protocols in a WAN Opt. tunnel

Different protocols may be more or less talkative or interactive. Mixing protocols in a tunnel may result in a delay for some of them. It is recommended to define protocol specific wan-optimization rules and restrict the ports to the necessary ones only for performance reasons.

Setting correct configuration options for CIFS WAN Opt.

Ensure that the WAN Optimization rules cover TCP ports 139 and 445 (on the same or two different rules). Also ensure that Transparent Mode is selected.

Setting correct configuration options for MAPI WAN Opt.

For MAPI WAN Optimization, only specify a rule with TCP port 135 (unless the MAPI control port is configured differently). Derived data sessions using other random ports will be handled by the CIFS wan-optimization daemon even with only the control port configured.

Testing WAN Opt. in a lab

- Ensure that WAN emulators are used to simulate the WAN. If no WAN emulator is used, it is expected to have better results without WAN Optimization than with WAN Optimization.
- To test the difference between cold transfers (first-time transfers) and warm transfers, it is recommended to generate a random file of the cold transfer to ensure that the test is the first time that the file has been seen.

Regarding byte compression and type of file

Enabling byte compression on file transfers already compressed (.jpeg files, compressed archive, etc.) won't provide any performance increase and could be seen as a misuse of CPU resources.

Regarding network address translation (NAT)

Selecting the NAT feature in a security policy does not have any influence on WAN Optimization traffic.

High Availability

There is no benefit to using active-active mode, so for pure WAN Optimization needs, use active-passive mode. Refer to the [FGCP high availability](#) section for other best practices related to HA.

Authentication with specific peers

Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure.

Virtual Domains (VDOMs)

VDOMs can provide separate firewall policies and, in NAT/Route mode, completely separate configurations for routing and VPN services for each connected network or organization. This section provides a list of best practices for configuring VDOMs.

Per-VDOM resource settings

While Global resources apply to resources shared by the whole FortiGate unit, per-VDOM resources are specific to only one Virtual Domain.

By default all the per-VDOM resource settings are set to no limits. This means that any single VDOM can use up all the resources of the entire FortiGate unit if it needs to do so. This would starve the other VDOMs for resources to the point where they would be unable to function. For this reason, it is recommended that you set some maximums on resources that are most vital to your customers.

Virtual domains in NAT/Route mode

Once you have enabled virtual domains and created one or more VDOMs, you need to configure them. It is recommended that you perform the following tasks in the order given (while you may not require all for your network topology):

1. Change the management virtual domain.
2. Configure FortiGate interfaces in a NAT/Route VDOM.
3. Configure VDOM routing.
4. Configure security policies for NAT/Route VDOMs.
5. Configure UTM profiles for NAT/Route VDOMs.
6. Test the configuration.

Virtual clustering

If you decide to disable override for clustering, as a result of persistent renegotiating, you should disable it for both cluster units.

Explicit proxy

- For explicit proxies, when configuring limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources prematurely.
- Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSSO, local database etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.
- For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.
- Set the explicit web proxy and explicit FTP proxy Default Firewall Policy Action to Deny. This means that a firewall policy is required to use these explicit proxies, allowing you to control access and impose security features.
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy.

Wireless

The following section contains a list of best practices for wireless network configurations with regard to encryption and authentication, geographic location, network planning, power usage, client load balancing, local bridging, SSIDs, and the use of static IPs.

Encryption and authentication

It is best practice to always enable the strongest user authentication and encryption method that your client supports. Fortinet recommends the following security, in order of strongest to weakest:

- WPA2 - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WPA - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WEP128 - 26 Hexadecimal digit key
- WEP64 - 10 Hexadecimal digit key
- None - Open system

Geographic location

Ensure that the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.

The maximum allowed transmitter power and permitted radio channels for Wi-Fi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

The location setting can only be changed from CLI. To change the country to France, for example, enter the following:

```
config wireless-controller setting
  set country FR
end
```

To see the list of country codes, enter a question mark ('?') in place of the country code.

Using an incorrect geographic location is a common error that can lead to unpredictable results on the client side.

Network planning

It is recommended that you perform a proper site survey prior positioning the wireless access point. In order to evaluate the coverage area environment, the following criteria must be taken into account:

- Size of coverage area
- Bandwidth required
- Client wireless capabilities

After completing a RF site survey, you'll have a good idea of the number and location of access points needed to provide users with adequate coverage and performance.

However, prior to installing the access points, be sure to determine the RF channel(s) you plan to use. This will ensure that users can roam throughout the facility with substantial performance.

To avoid co-channel interference, adjacent Wi-Fi APs must be configured to use non-overlapping channels. Otherwise, you'll find poor performance will degrade because of interference between access points.

It is recommended to statically configure the non-overlapping channels on every access point, using one Custom AP profile per AP (or group of APs). If static configuration cannot be used, the FortiOS Wi-Fi Controller includes the Automatic Radio Resource Provisioning (ARRP) feature.

Lowering the power level to reduce RF interference

Relevant Product(s): FortiAP

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. If possible, reduce the transmitter power of your wireless access point so that the signal is not available beyond the areas where it is needed. Auto Tx Power Control can be enabled to automatically adjust the transmit power.

In cases where customers complain about slow wireless traffic through a FortiAP, it might be necessary to try to reduce the possibility of RF interference. It is best practice not to locate FortiAPs near steel beams or other interfering materials. You can try using a wireless sniffer tool to collect the wireless packets and then analyze the extent of air interference.

A common mistake is spacing FortiAPs based upon the 5Ghz radio frequency. The 2.4Ghz signal travels further.

You have two options when confronted with slow wireless traffic through a FortiAP:

Option #1: Reducing transmit power

Perform a speed test and record the results. Set one of the radios on a FortiAP to be in dedicated monitoring mode. Then observe how many APs are detected. If the number of APs is too high (i.e., greater than 20), try reducing the transmit power in the WTP profile for the FortiAPs until the number of dedicated APs has dropped significantly.

Repeat the speed test.

Option #2: Ensuring that VAPs are distributed over the available channels

No built-in tools are available to measure RF interference directly. However, FortiOS 5.0 does allow for automatic power adjustment, which should minimize the occurrence of RF interference.

Wireless client load balancing

Wireless load balancing allows your wireless network to more efficiently distribute wireless traffic among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- **Access Point Hand-off** - The wireless controller signals a client to switch to another access point.
- **Frequency Hand-off** - The wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Local bridging

Whenever possible, use local bridging to offload the CAPWAP tunnel. Note that in this case, Wi-Fi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN. The vlan ID can only be configured

from the CLI:

```
config wireless-controller vap
  edit "vaplocalbridge"
    set vdom "root"
    set ssid "testvaplocalbridge"
    set local-bridging enable
    set vlanid 40 ---> only available in CLI
  next
end
```

Advertising SSIDs

- It is highly recommended to advertise the SSID. It makes it easier for customers and wireless clients. Also, if you 'hide' the SSID (known as 'network cloaking'), then clients will always look for it when they're outside the coverage area, which searches for known SSIDs, in effect leaking the SSID anyway. Refer to [RFC 3370](#). Furthermore, many of the latest Broadcom drivers do not support hidden SSID for WPA2.
- For security reason, you might want to prevent direct communication between your wireless clients. In this case, enable Block Intra-SSID Traffic (in the SSID configuration).
- In a network with multiple wireless controllers, you need to change the mesh SSID so that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to **WiFi & Switch Controller > SSID** to change the SSID. Fortinet also recommends that you create a new preshared key instead of using the default.

Using static IPs in a CAPWAP configuration

In a large FortiAP deployment with more than 20 FortiAPs connecting to a Fortigate Wireless Controller (AC), it is recommended to use static IPs on the access points instead of DHCP, setting the AC IP statically and the AC discovery type to static (Type 1), instead of learning it through broadcast, multicast, or DHCP.

This makes management of the APs easier since you know the exact IP of each access point. Troubleshooting also becomes easier as the debug of the AC controller won't continuously attempt the different discovery methods in sequence (broadcast > multicast > static).

Logging and reporting

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- What FortiGate activities you want and/or need logged (for example, security features).
- The logging device best suited for your network structure.
- If you want or require archiving of log files.
- Ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

- Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
- Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
- If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the IM usage dashboard widget or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
- Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

- When downloading log messages and viewing them on a computer, the log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.

System memory and hard disks

If the FortiGate unit has a hard disk, it is enabled by default to store logs. This also means that you do not have to enable this and configure the settings for logging to the hard disk, but modify these settings so that it is configured for your network logging requirements.

If the FortiGate unit has only flash memory, disk logging is disabled by default, as it is not recommended. Constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. It must be enabled in the CLI under config log disk setting.

For some low-end models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

Chapter 5 - FortiOS Carrier

This FortiOS Handbook chapter contains the following sections:

- [What's new in FortiOS Carrier 6.0](#)
 - Features and improvements that have been added in version FortiOS 5.6
- [Overview of FortiOS Carrier features](#)
 - The high altitude overview of FortiOS Carrier
- ["MMS Concepts" on page 382](#)
 - Basic background on MMS and its concepts so that there is some context to the settings used in the MMS configuration
- ["MMS Configuration" on page 397](#)
 - Listing of the MMS configuration options and settings
 - Procedures and insights in the configuration of the MMS components of FortiOS Carrier
- [GTP basic concepts](#)
 - Basic background on GTP and its concepts so that there is some context to the settings used in the GTP configuration
- ["GTP Configuration" on page 462](#)
 - Listing of the GTP configuration options and settings
 - Procedures and insights in the configuration of the GTP components of FortiOS Carrier
- ["SCTP Concepts" on page 506](#)
 - Background on SCTP, and how it makes the FortiOS Carrier different than the FortiGate
- ["Troubleshooting" on page 510](#)
 - Some basic procedures for troubleshooting FortiOS Carrier

What's new in FortiOS Carrier 6.0

The following list contains new firewall features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- [FGSP support over GTP on page 1](#)
- [GTP Stats via SNMP on page 488](#)
- [GTP Shared Tunnel Limit on page 486](#)

The GTP Shared Tunnel limit is the total number of GTP tunnels created by multiple GTP profiles. A Global shared tunnel limit gives the flexibility of limiting the number of GTP tunnels flowing through different profiles. A shared global limit is defined and then referenced in the profiles. Before FortiOS version 6, the GTP tunnel limit could be set on a per-profile basis. The GTP tunnel limits can now be set per VDOM.

Per profile tunnel limiting is still possible but restrictive limit between the global limit and the profile limit will be enforced.

Example:

- Global shared tunnel limit defined as 12
- GTP Profile A - per profile tunnel limit defined as 8
- GTP Profile B - per profile tunnel limit defined as 14

You can have eight tunnels active in profile A, but the ninth will be dropped due to the profile limit of 8.

If Profile A still has 8 active tunnels, you can have four tunnels active in profile B and the fifth will be dropped even though the profile allows 14, because the global share limit is 12.

```
next
edit "gtp2"
  set global-tunnel-limit "gtp-tl-1"
end
```

Overview of FortiOS Carrier features

FortiOS Carrier specific features include Multimedia messaging service (MMS) protection, and GPRS Tunneling Protocol (GTP) protection.

All FortiGate units, carrier-enabled or not, are capable of handling Stream Control Transmission Protocol (SCTP) traffic, which is a protocol designed for and primarily used in Carrier networks.

This section includes:

Overview

FortiOS Carrier provides all the features found on FortiGate units plus added features specific to carrier networks: MMS and GTP.

MMS

MMS is a standard for sending messages that include multimedia content between mobile phones. MMS is also popular as a method of delivering news and entertainment content including videos, pictures, and text. Carrier networks include four different MMS types of messages — MM1, MM3, MM4, and MM7.

GTP

The GPRS Tunneling Protocol (GTP) runs on GPRS carrier networks. GPRS is a GSM packet radio standard. It provides more efficient usage of the radio interface so that mobile devices can share the same radio channel. FortiOS supports GTPv1 and GTPv2.

GPRS provides direct connections to the Internet (TCP/IP) and X.25 networks for point-to-point services (connection-less/connection oriented) and point-to-multipoint services (broadcast).

GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and it is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based) that converts the message from radio to wired, and sends the message to the carrier network and eventually the Internet (wired carrier network). See [GTP](#).

MMS Concepts

MMS background

MMS is a common method for mobile users to send and receive multimedia content. A Carrier network supports MMS across its network. This makes up the MMS Service Provider Network (MSPN).

Messages can be sent or received between the MMSC and a number of other services including the Internet, content providers, or other carriers. Each of these different service connections uses different MMS formats including MM1 and MM7 messages (essentially HTTP format), and MM3 and MM4 messages (SMTP formatted). These different formats reflect the different purposes and content for each type of MMS message.

MMS content interfaces

MMS content interfaces

MMS messages are sent from devices and servers to other devices and servers using MMS content interfaces

There are eight interfaces defined for the MMS standard, referred to as MM1 through MM8. The most important of these interfaces for the transfer of data is the MM1 interface, as this defines how mobile users communicate from the mobile network to the Multimedia Message Service Center (MMSC). MMS content to be monitored and controlled comes from these mobile users and is going to the provider network.

Other MMS content interfaces that connect a service provider network to other external sources can pose threats as well. MM3 handles communication between the Internet and the MMSC and is a possible source of viruses and other content problems from the Internet. MM4 handles communication between different content provider MMSCs. Filtering MM4 content protects the service provider network from content sent from foreign service providers and their subscribers. Finally MM7 is used for communication between content providers and the MMSC. Filtering MM3 content can also keep harmful content off of the service provider network.

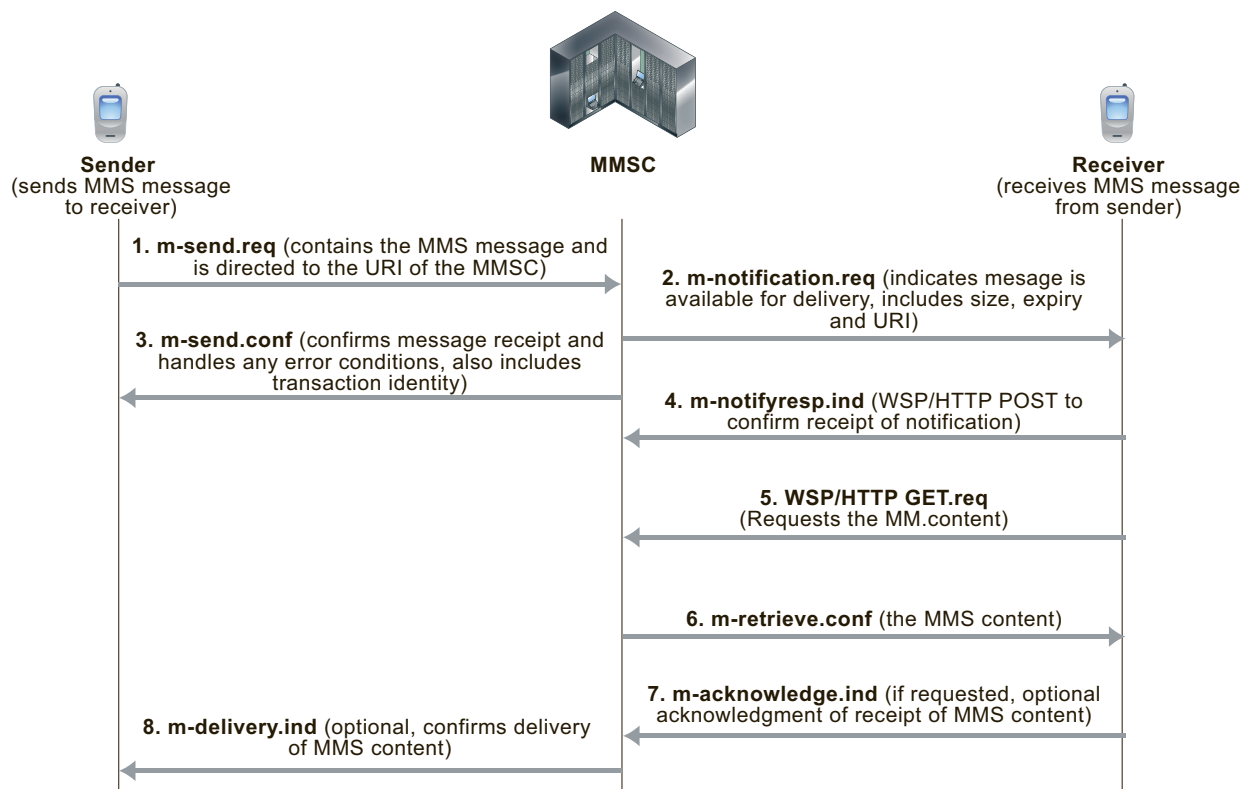

MMS content interfaces

Type	Transaction	Similar to
MM 1	Handset to MMSC	HTTP
MM 3	Between MMSC and Internet	SMTP
MM 4	Between Operator MMSCs	SMTP
MM 7	Content Providers to MMSC	HTTP and SOAP

How MMS content interfaces are applied

As shown below, the sender's mobile device encodes the MMS content in a form similar to MIME email message (MMS MIME content formats are defined by the MMS Message Encapsulation specification). The encoded message is then forwarded to the service provider's MMSC. Communication between the sending device and the MMSC uses the MM1 content interface. The MM1 content interface establishes a connection and sends an MM1 send request (`m-send.req`) message that contains the MMS message. The MMSC processes this request and sends back an MM1 send confirmation (`m-send.conf`) HTTP response indicating the status of the message — accepted or an error occurred, for example.

MM1 transactions between senders and receivers and the MMSC

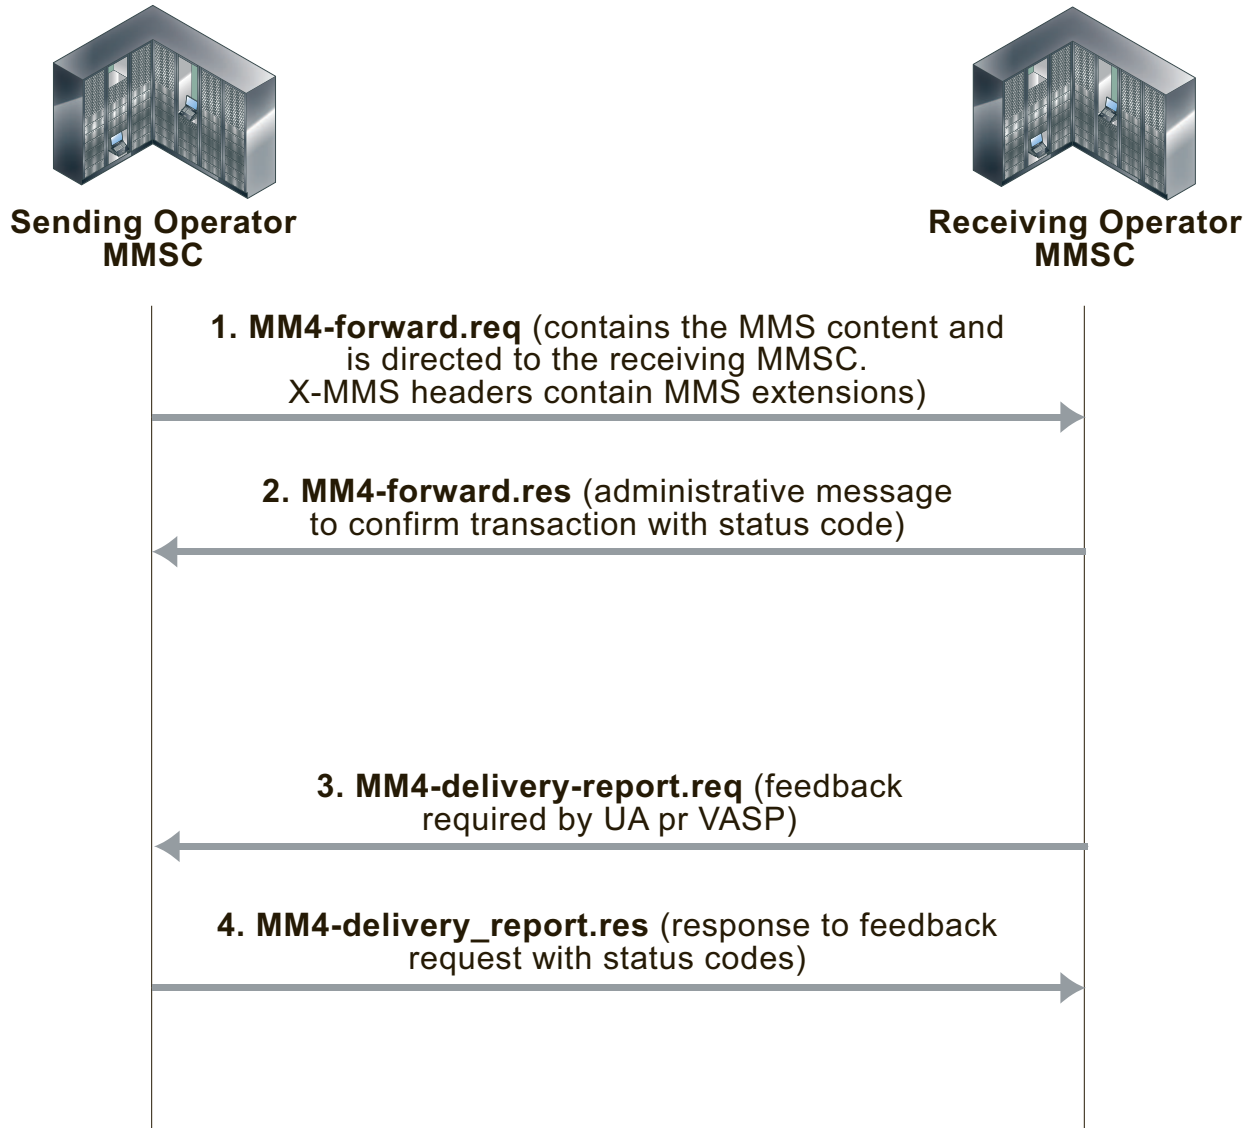

If the recipient is on another carrier, the MMSC forwards the message to the recipient's carrier. This forwarding uses the MM4 content interface for forwarding content between operator MMSCs (see the figure below).

Before the MMSC can forward the message to the final recipient, it must first determine if the receiver's handset can receive MMS messages using the MM1 content interface. If the recipient can use the MM1 content interface, the content is extracted and sent to a temporary storage server with an HTTP front-end.

To retrieve the message, the receiver's handset establishes a connection with the MMSC. An HTTP get request is then sent from the recipient to the MMSC. This message contains the URL where the content of the message is stored. The MMSC responds with a retrieve confirmation (`m-retrieve.conf`) HTTP response that contains the message.

MM4 messages sent between operator MMSCs

This causes the receiver's handset to retrieve the content from the embedded URL. Several messages are exchanged to indicate status of the delivery attempt. Before delivering content, some MMSCs also include a content adaptation service that attempts to modify the multimedia content into a format suitable for the recipient's handset.

If the receiver's handset is not MM1 capable, the message can be delivered to a web based service and the receiver can view the content from a normal Internet browser. The URL for the content can be sent to the receiver in an SMS text message. Using this method, non-MM1 capable recipients can still receive MMS content.

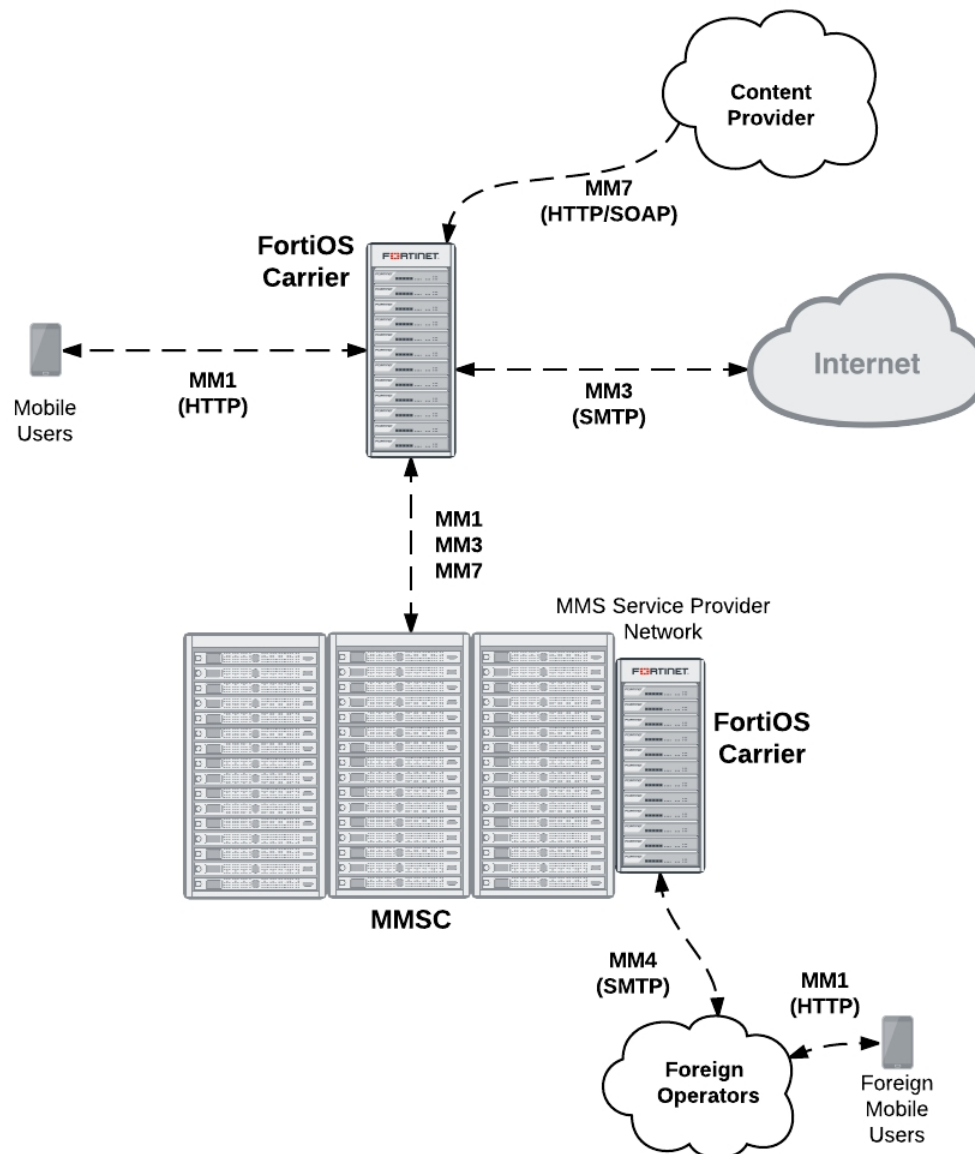

The method for determining whether a handset is MMS capable is not specified by the standards. A database is usually maintained by the operator, and in it each mobile phone number is marked as being associated with a legacy handset or not. It can be a bit hit and miss since customers can change their handset at will and this database is not usually updated dynamically.

Email and web-based gateways from MMSC to the Internet use the MM3 content interface. On the receiving side, the content servers can typically receive service requests both from WAP and normal HTTP browsers, so delivery via the web is simple. For sending from external sources to handsets, most carriers allow MIME encoded message to be sent to the receiver's phone number with a special domain.

How FortiOS Carrier processes MMS messages

MMS messages can be vectors for propagating undesirable content such as spam and viruses. FortiOS Carrier can scan MMS messages sent using the MM1, MM3, MM4, and MM7 content interfaces. You can configure FortiOS Carrier to scan MMS messages for spam and viruses by configuring and adding MMS protection profiles and adding the MMS protection profiles to security policies. You can also use MMS protection profiles to apply content blocking, carrier endpoint filtering, MMS address translation, sending MMS notifications, DLP archiving of MMS messages, and logging of MMS message activity.

FortiOS Carrier MMS processing

FortiOS Carrier can send MMS messages to senders informing those senders that their devices are infected. FortiOS Carrier can also send MMS notifications to administrators to inform them of suspicious activity on their networks.

For message floods and duplicate messages, FortiOS Carrier does not send notifications to message senders but does send notifications to administrators and sends messages to sender handsets to complete MM1 and MM4 sessions.

Where MMS messaging uses the TCP/IP set of protocols, SMS text messaging uses the Signaling System Number 7 (SS7) set of protocols, which is not supported by FortiOS.

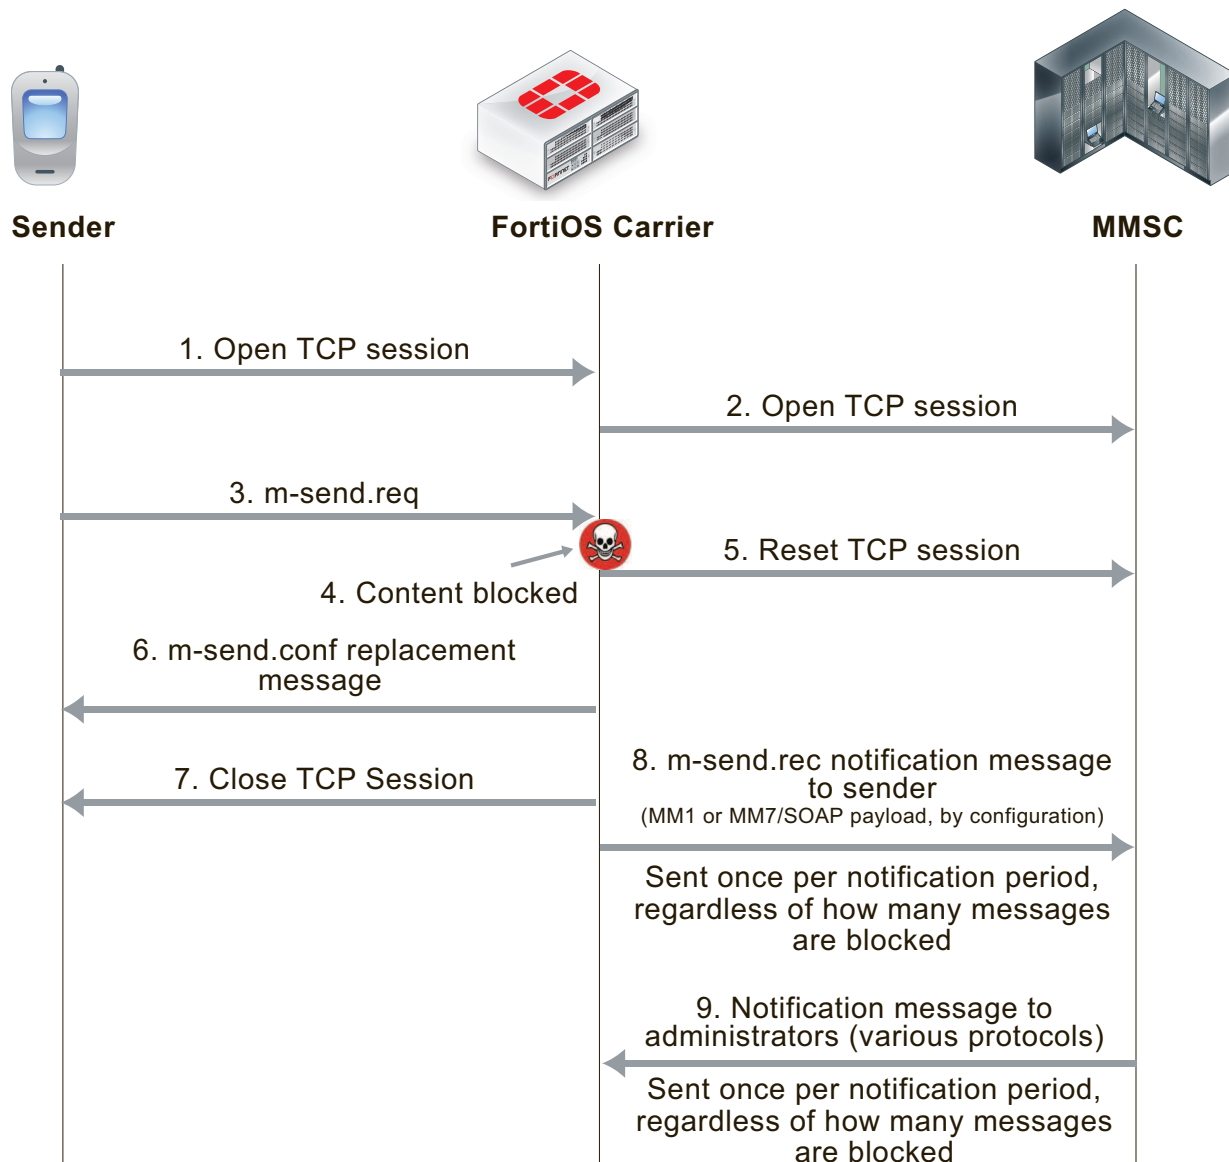

FortiOS Carrier and MMS content scanning

The following section applies to MMS content scanning, including virus scanning, file filtering, content spam filtering, carrier endpoint filtering, and MMS content checksum filtering.

MM1 Content Scanning

During MM1 content scanning a message is first transmitted from the sender, establishing a connection with the MMSC. FortiOS Carrier intercepts this connection and acts as the endpoint. FortiOS Carrier then establishes its own connection to the MMSC. Once connected, the client transmits its `m-send.req` HTTP post request to FortiOS Carrier which scans it according to the MMS protection profile settings. If the content is clean, the message is forwarded to the MMSC. The MMSC returns `m-send.conf` HTTP response through FortiOS Carrier to the sender.

If FortiOS Carrier blocks the message (for example because a virus was found, see the figure below), FortiOS Carrier resets the connection to the MMSC and sends `m-send.conf` HTTP response back to the sender. The response message can be customized using replacement messages. FortiOS Carrier then terminates the connection. Sending back an `m-send.conf` message prevents the sender from trying to send the message again.

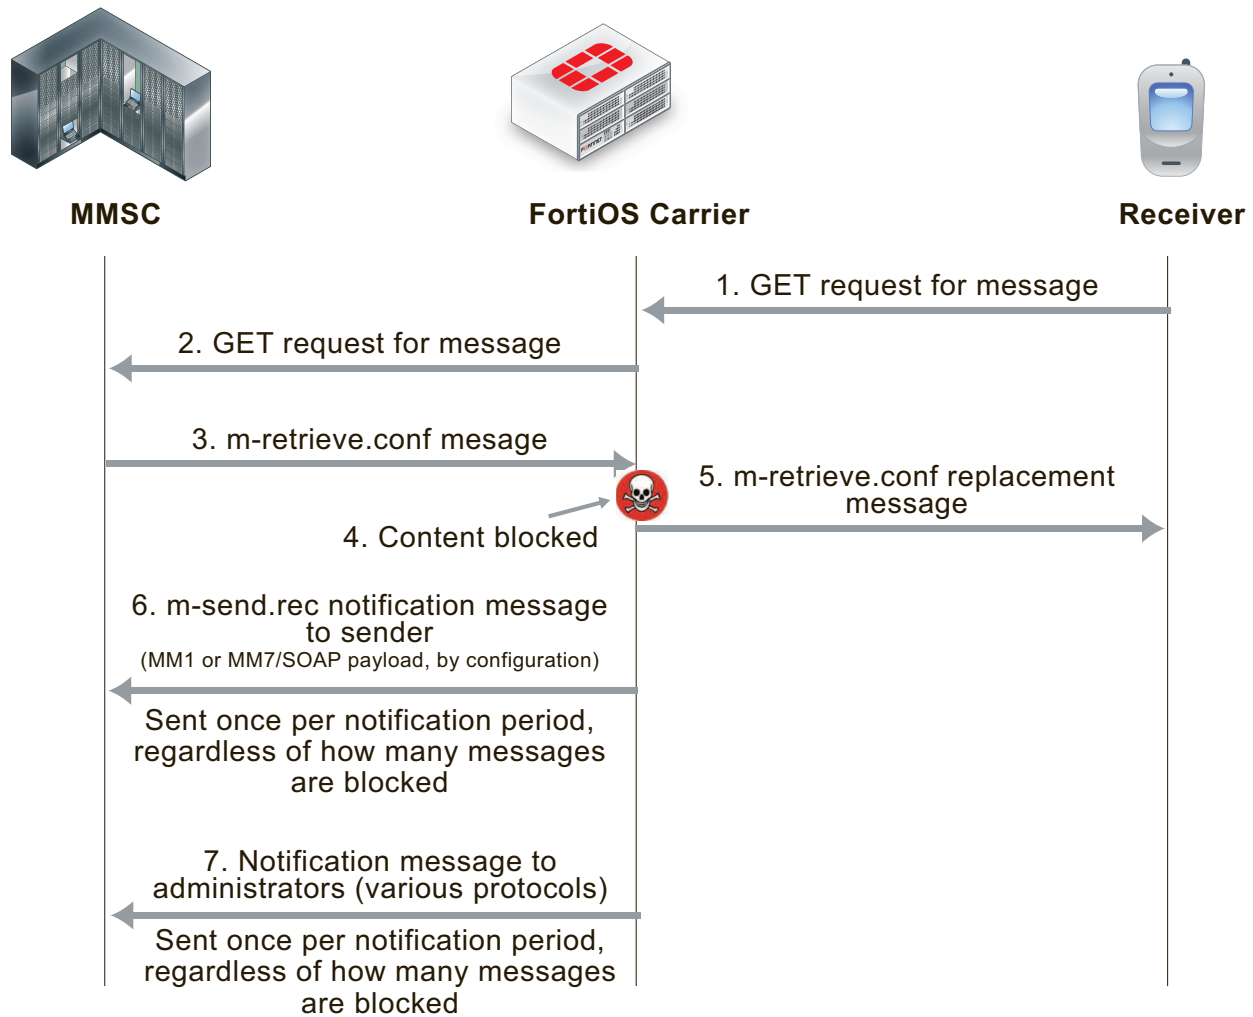

MM1 MMS scanning of message sent by sender (blocking m.send.req messages)

FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the sender to notify them of blocked messages.

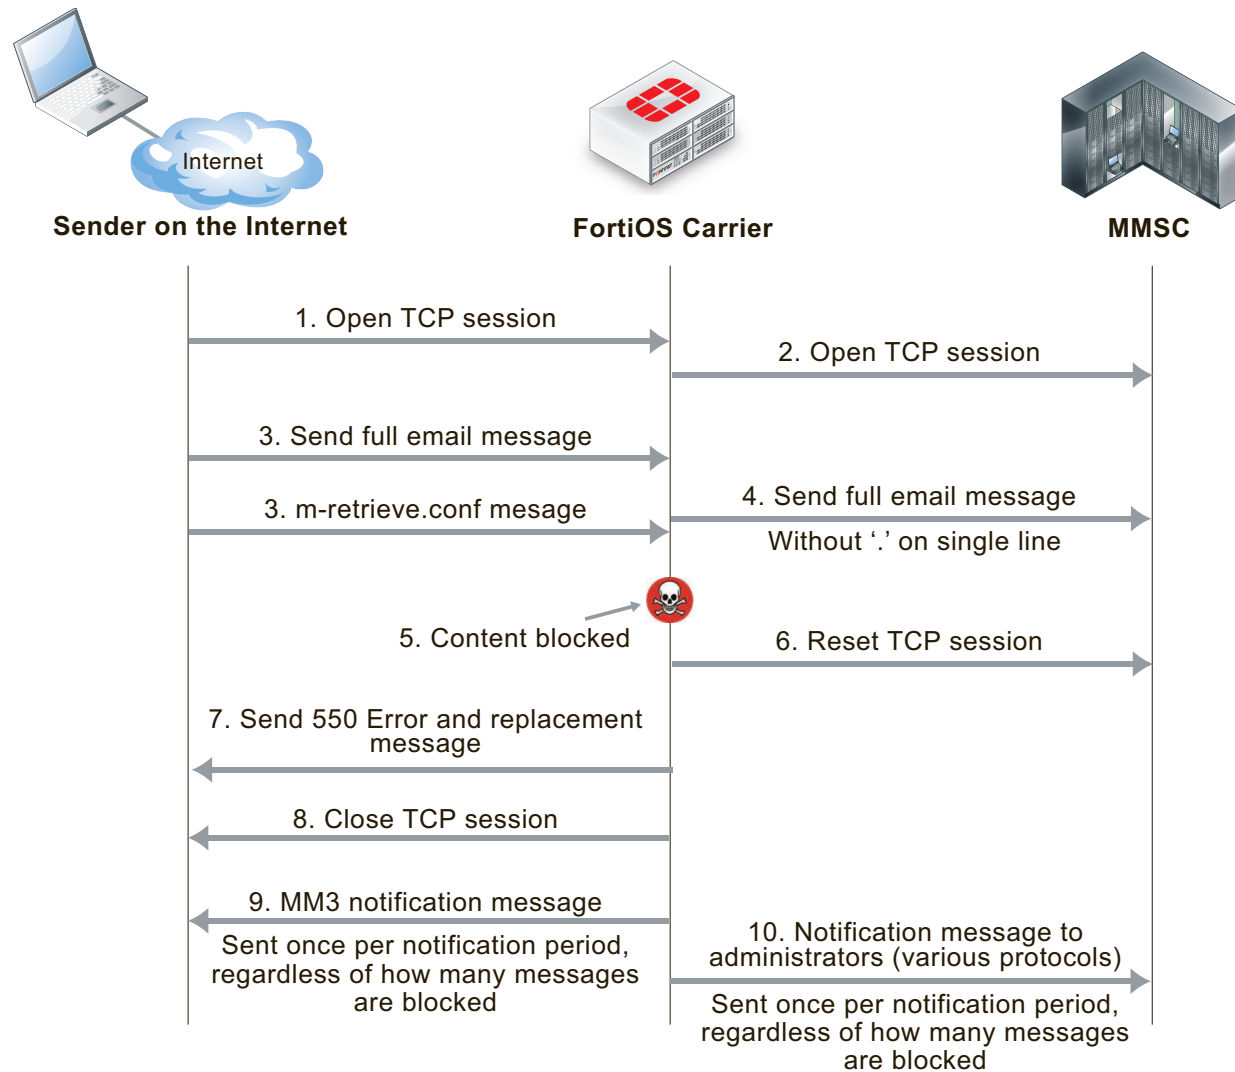

Filtering message retrieval

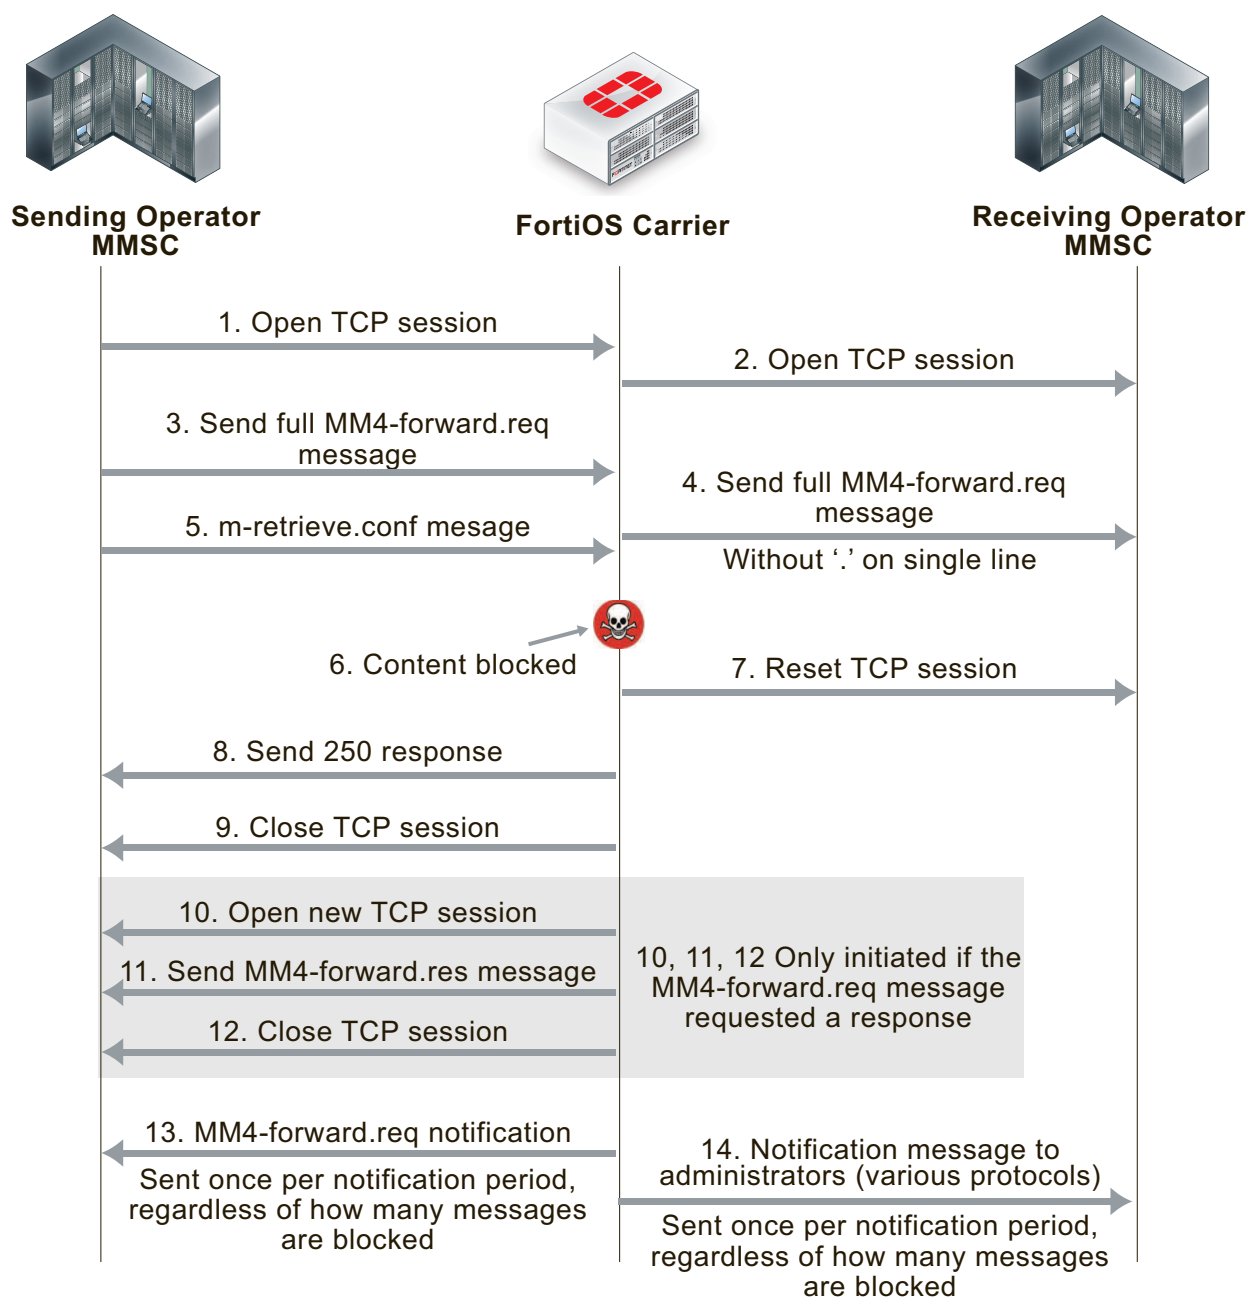

FortiOS Carrier intercepts the connection to the MMSC, and the `m-retrieve.conf` HTTP response from the MMSC is scanned according to the MMS content scanning settings. If the content is clean, the response is forwarded back to the client. If the content is blocked, FortiOS Carrier drops the connection to the MMSC. It then builds an `m-retrieve.conf` message from the associated replacement message and transmits this back to the client.

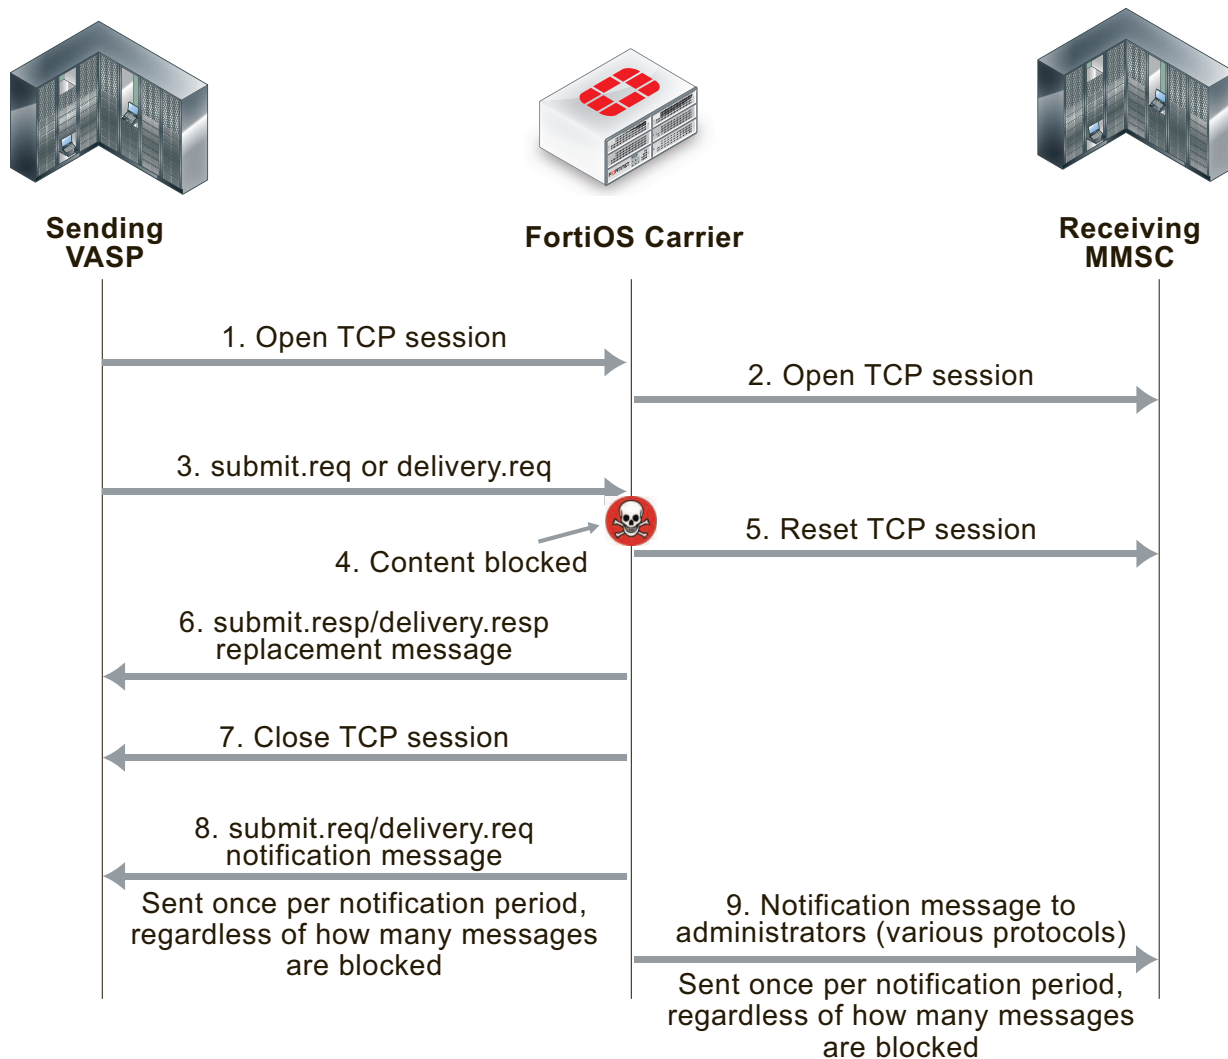

FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the receiver to notify them of blocked messages.

MM1 MMS scanning of messages received by receiver (blocking m.retrieve.conf messages)

Filtering MM3 and MM4 messages works in an similar way to MM1 (see the figures below). FortiOS Carrier intercepts connections to the MMSC, and scans messages as configured. When messages are blocked, FortiOS Carrier closes sessions as required, sends confirmation messages to the sender, notifies administrators, and notifies senders and receivers of messages.

MM3 MMS scanning of messages sent from a sender on the Internet to an MMSC

MM4 MMS scanning of messages sent between operator MMSCs

MM7 MMS scanning of messages sent between a VASP and an MMSC**FortiOS Carrier and MMS duplicate messages and message floods**

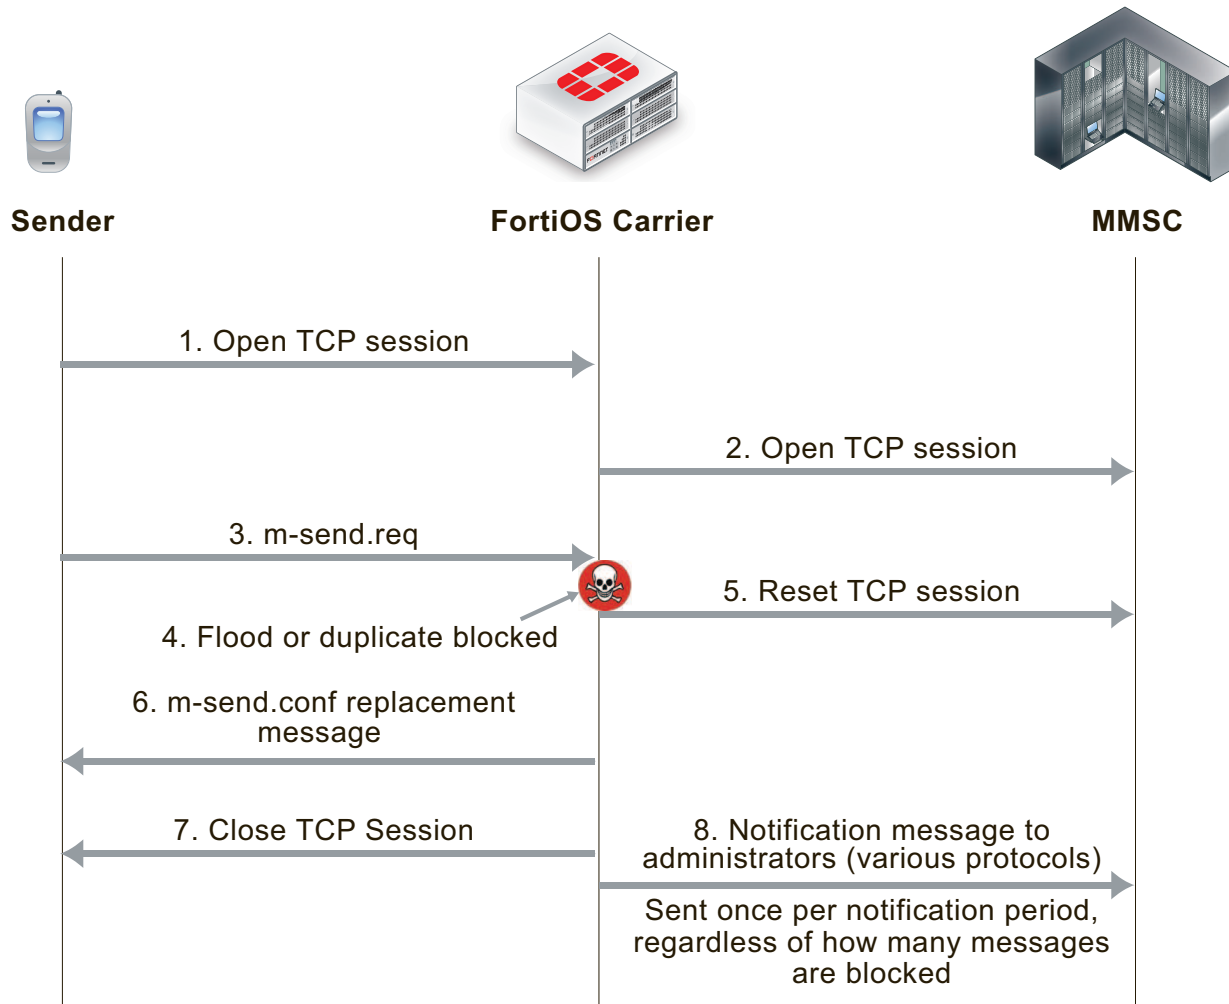

FortiOS Carrier detects duplicate messages and message floods for the MM1 and MM4 interfaces. How FortiOS Carrier detects and responds to duplicate messages and message floods is different from how FortiOS Carrier detects and responds to viruses and other MMS scanning protection measures.

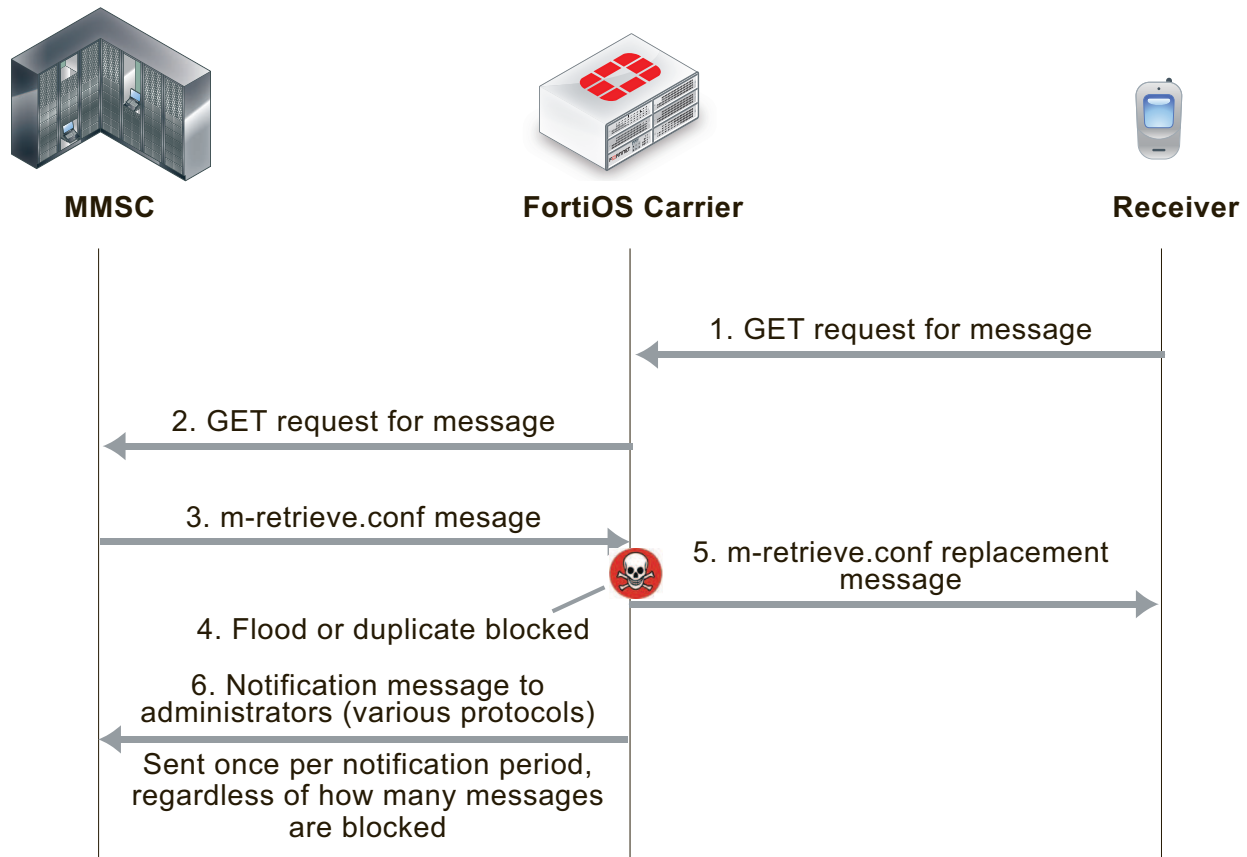

For message floods and duplicate messages, the sender does not receive notifications about floods or duplicate messages, as if the sender is an attacker they can gain useful information about flood and duplicate thresholds. Plus, duplicate messages and message floods are usually a result of a large amount of messaging activity and filtering of these messages is designed to reduce the amount of unwanted messaging traffic. Adding to the traffic by sending notifications to senders and receivers could result in an increase in message traffic.

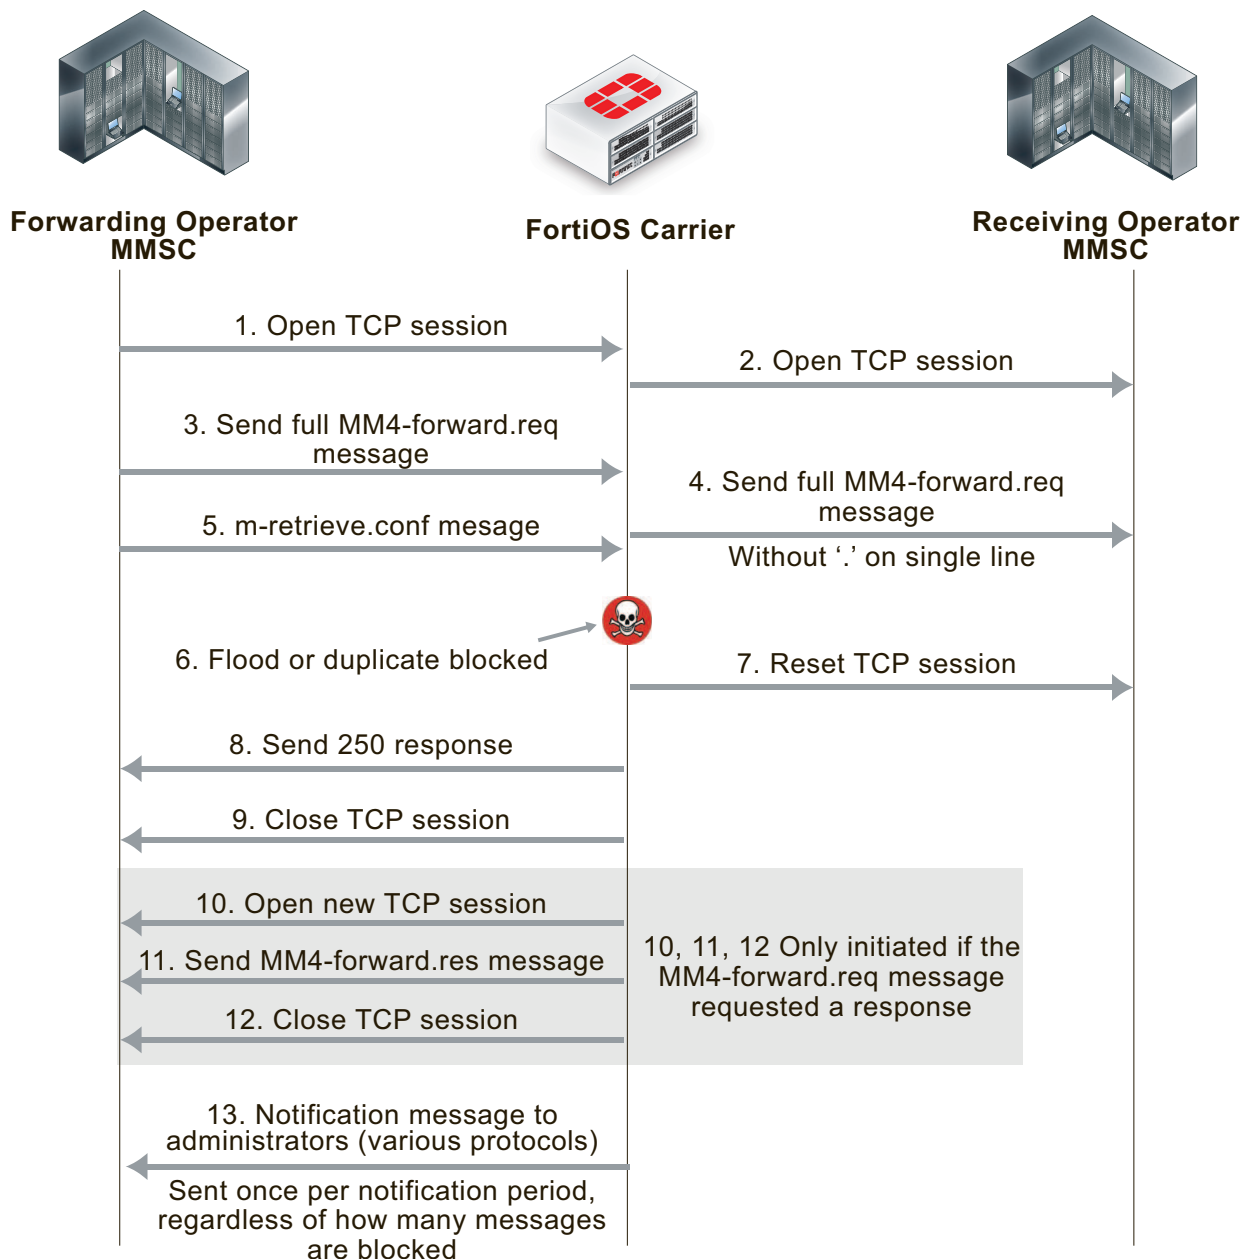

You can create up to three thresholds for detecting duplicate messages and message floods. For each threshold you can configure the FortiOS Carrier unit to respond by logging the activity, archiving or quarantining the messages, notifying administrators of the activity, and by blocking the messages. In many cases you may only want to configure blocking for higher activity thresholds, and to just monitor and send administrator notifications at lower activity thresholds.

When a block threshold is reached for MM1 messages, FortiOS Carrier sends `m-send.conf` or `m-retrieve.conf` messages to the originator of the activity. These messages are sent to end the MM1 sessions, otherwise the originator would continue to re-send the blocked message. When a block threshold is reached for MM4, FortiOS Carrier sends a `MM4-forward.res` message to close the MM4 session. An MM4 message is sent only if initiated by the originating `MM4-forward.req` message.

MM1 message flood and duplicate message blocking of sent messages

MM1 message flood and duplicate message blocking of received messages

MM4 message flood and duplicate message blocking**MMS protection profiles**

An MMS protection profile is a group of settings that you can apply to an MMS session matched by a security policy.

MMS protection profiles are easy to configure and can be used by more than one security policy. You can configure a single MMS protection profile for the different traffic types handled by a set of security policies that require identical protection levels and types. This eliminates the need to repeatedly configure those same MMS protection profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need only moderate protection. You would configure two separate MMS protection profiles to provide the different levels of protection: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS Protection Profile, you need to add it to a security policy to apply the profile to MMS traffic.

Bypassing MMS protection profile filtering based on carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from MMS protection profile filtering. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from all scanning, all messages from matching carrier endpoints bypass MMS protection profile filtering. See Bypassing message flood protection based on user's carrier endpoints.

Applying MMS protection profiles to MMS traffic

To apply an MMS protection profile you must first create the MMS protection profile and then add the MMS protection profile to a security policy by enabling the Carrier security profile. The MMS protection profile then applies itself to the traffic accepted by that security policy.

MMS protection profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS protection profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS protection profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS protection profile.

To add an MMS protection profile to a security policy

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New** to add an MMS protection profile.
3. Configure as needed, and save.
4. Go to **Policy & Objects > IPv4 Policy**.
5. Select **Create New** to add a security policy, or select an existing policy and **Edit** to add the MMS profile.
6. Configure the security policy as required.
7. Enable **MMS Profile**, and select the MMS profile to add to the security policy.
8. Select **OK**.

MMS Configuration

MMS profiles

Since MMS profiles can be used by more than one security policy, you can configure one profile for the traffic types handled by a set of security policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

If the security policy requires authentication, do not select the MMS profile in the security policy. This type of profile is specific to the authenticating user group. For details on configuring the profile associated with the user group, see User Groups in the Authentication guide.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate protection profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS profile, you can then apply the profile to MMS traffic by applying it to a security policy.

MMS profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS profile.

The MMS Profile page contains options for each of the following:

- MMS scanning
- MMS Bulk Email Filtering Detection
- MMS Address Translation
- MMS Notifications
- DLP Archive
- Logging

MMS profile configuration settings

The following are MMS profile configuration settings in **Security Profiles > MMS Profile**.

MMS Profile page	
Lists each individual MMS profile that you created. On this page, you can edit, delete or create an MMS profile.	
Create New	Creates a new MMS profile. When you select Create New , you are automatically redirected to the New MMS Profile page.
Edit	Modifies settings within an MMS profile. When you select Edit , you are automatically redirected to the Edit MMS Profile.
Delete	Removes an MMS profile from the list on the MMS Profile page.
	To remove multiple MMS profiles from within the list, on the MMS Profile page, in each of the rows of the profiles you want removed, select the check box and then select Delete .
	To remove all MMS profiles from the list, on the MMS Profile page, select the check box in the check box column, and then select Delete .
Name	The name of the MMS profile.

Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus**), 1 appears in **Ref.** .

To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object.

To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:

Ref.

View the list page for these objects – automatically redirects you to the list page where the object is referenced at.

Edit this object – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page.

View the details for this object – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

New MMS Profile page

Provides settings for configuring an MMS profile. This page also provides settings for configuring DLP archives and logging.

Profile Name	Enter a name for the profile.
Comments	Enter a description about the profile. This is optional.
MMS Scanning	Configure MMS Scanning options.
MMS Bulk Email Filtering Detection	Configure MMS Bulk Email options.
MMS Address Translation	Configure MMS Address Translation options.
MMS Notifications	Configure MMS Notification options.
DLP Archive	Configure DLP archive option.
Logging	Configure logging options.

MMS scanning options

You can configure MMS scanning protection profile options to apply virus scanning, file filtering, content filtering, carrier endpoint blocking, and other scanning to MMS messages transmitted using the MM1, MM3, MM4 and

MM7 protocols.

The following are the MMS Scanning options that are available within an MMS profile. You can create an MMS profile in **Security Profiles > MMS Profile** or edit an existing one. You must expand MMS Scanning to access the following options.

MMS Scanning section of the New MMS Profile page	
Monitor Only	<p>Select to cause the unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Select this option to be able to report on viruses and other problems in MMS traffic without affecting users.</p> <p>Tip: Select Remove Blocked if you want the unit to actually remove content intercepted by MMS scanning options.</p>
Virus Scan	<p>Select to scan attachments in MMS traffic for viruses.</p> <p>Since MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configuration also applies to MM1 and MM7 scanning.</p> <p>MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configuration also applies to MM3 and MM4 scanning.</p>
Scan MM1 message retrieval	<p>Select to scan message retrievals that use MM1. If you enable Virus Scan for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.</p>
Remove Blocked	<p>Select to remove blocked content from each protocol and replace it with the replacement message.</p> <p>Select Constant if the unit is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message.</p> <p>Tip: If you only want to monitor blocked content, select Monitor Only.</p>
Content Filter	<p>Select to filter messages based on matching the content of the message with the words or patterns in the selected web content filter list.</p> <p>For information about adding a web content filter list, see the FortiGate CLI Reference.</p>
Carrier Endpoint Block	<p>Select to add Carrier Endpoint Filtering in this MMS profile. Select the carrier endpoint filter list to apply it to the profile.</p>

MMS Scanning section of the New MMS Profile page

MMS Content Checksum	Select to add MMS Content Checksum in this MMS profile. Select the MMS content checksum list to apply it to the profile.
Pass Fragmented Messages	Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.
Comfort Clients	<p>Select client comforting for MM1 and MM7 sessions.</p> <p>Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.</p>
Comfort Servers	<p>Select server comforting for each protocol.</p> <p>Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for the unit to buffer and scan large POST requests from slow clients.</p>
Interval (1-900 seconds)	Enter the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.
Amount (1-10240 bytes)	The number of bytes sent by client or server comforting at each interval.
Oversized MMS Message	<p>Select Block or Pass for files and email messages exceeding configured thresholds for each protocol.</p> <p>The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.</p>
Threshold (1KB - 800 MB)	Enter the oversized file threshold and select KB or MB. If a file is larger than the threshold the file is passed or blocked depending on the Oversized MMS Message setting. The web-based manager displays the allowed threshold range. The threshold maximum is 10% of the unit's RAM.

MMS Bulk Anti-Spam Detection options

You can use the MMS bulk email filtering options to detect and filter MM1 and MM4 message floods and duplicate messages. You can configure three thresholds that define a flood of message activity and three thresholds that define excessive duplicate messages. The configuration of each threshold includes the response actions for the threshold.

The configurable thresholds for each of the flood and duplicate sensors and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

You can also add MSISDN to the bulk email filtering configuration and select a subset of the bulk email filtering options to applied to these individual MSISDNs.

You must first select MM1 and/or MM4 to detect excessive message duplicates. If excessive message duplicates are detected, the unit will perform the **Duplicate Message Action** for the specified duration.

You can configure three duplicate message thresholds and enable them with separate values and actions. They are labeled Duplicate Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Duplicate Threshold 1 and Duplicate Threshold 2, but you cannot disable Duplicate Threshold 1 and enable Duplicate Threshold 2.

When traffic accepted by a security policy that contains an MMS profile with duplicate message configured receives MM1 or MM4 duplicate messages that match a threshold configured in the MMS protection profile, the unit performs the duplicate message action configured for the matching threshold.

You can configure three message flood thresholds and enable them with separate values and actions. They are labeled Flood Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

When traffic accepted by a security policy that contains an MMS protection profile with message flooding configured experiences MM1 or MM4 message flooding that matches a threshold configured in the MMS profile, the unit performs the message flood action configured for the matching threshold.

MMS Bulk Anti-Spam Detection

This section of the New MMS Profile page contains numerous sections where you can configure specific settings for flood threshold, duplicate threshold and recipient MSISDNs.

Message Flood

The message flood settings for each flood threshold. Expand each to configure settings for a threshold.

Flood Threshold 1	Expand to reveal the flood threshold settings for Flood Threshold 1. The settings for Flood Threshold 1 are the same for Flood Threshold 2 and 3.
Enable	Select to apply Flood Threshold 1 to the MSISDN exception.
Message Flood Window	Enter the period of time during which a message flood will be detected if the Message Flood Limit is exceeded. The message flood window can be 1 to 2880 minutes (48 hours).
Message Flood Limit	Enter the number of messages which signifies a message flood if exceeded within the Message Flood Window .
Message Flood Block Time	Enter the amount of time during which the unit performs the Message Flood Action after a message flood is detected.

Message Flood Action	Select one or more actions that the unit is to perform when a message flood is detected.
Flood Threshold 2	Expand to configure settings for Flood Threshold 2 or 3 respectively.
Flood Threshold 3	
Duplicate Message	
The duplicate message threshold settings. Expand each to configure settings for a threshold.	
MM1 Retrieve Duplicate Enable	Select to scan MM1 <code>mm1-retr</code> messages for duplicates. By default, <code>mm1-retr</code> messages are not scanned for duplicates as they may often be the same without necessarily being bulk or spam.
Enable	Select to enable the selected duplicate message threshold and to make the rest of the options available for configuration.
Duplicate Message Window	Enter the period of time during which excessive message duplicates will be detected if the Duplicate message Limit it exceeded. The duplicate message window can be 1 to 2880 minutes (48 hours).
Duplicate Message Limit	Enter the number of messages which signifies excessive message duplicates if exceeded within the Duplicate Message Window.
Duplicate Message Block Time	Enter the amount of time during which the unit will perform the Duplicate Message Action after a message flood is detected.
Duplicate Message Action	Select one or more actions that the unit is to perform when excessive message duplication is detected.
Duplicate Threshold 2	Expand to configure settings for Duplicate Threshold 2 or 3 respectively.
Duplicate Threshold 3	
Recipient MSISDN	
The recipient Mobile Subscriber Integrated Services Digital Network Number (MSISDN) settings for each recipient MSISDN. When you select Create New , you are automatically redirected to the New MSISDN page.	
You need to save the profile before you can add MSISDNs.	
Recipient MSISDN	The recipient MSISDN.
Flood Threshold 1	Check to enable Flood Threshold 1 settings for this MSISDN.
Flood Threshold 2	Check to enable Flood Threshold 2 settings for this MSISDN.
Flood Threshold 3	Check to enable Flood Threshold 3 settings for this MSISDN..

Duplicate Threshold 1	Check to enable Duplicate Threshold 1 settings for this MSISDN.
Duplicate Threshold 2	Check to enable Duplicate Threshold 2 settings for this MSISDN..
Duplicate Threshold 3	Check to enable Duplicate Threshold 3 settings for this MSISDN..
Edit	Modifies the settings of a Recipient MSISDN in the Recipient MSISDN list. When you select Edit , you are automatically redirected to the New MSISDN page.
Delete	Removes a Recipient MSISDN in the Recipient MSISDN list within the Recipient MSISDN section of the page.
New MSISDN page	
Create New	Creates a new Recipient MSISDN. When you select Create New , you are automatically redirected to the New MSISDN page.
Recipient MSISDN	Enter a name for the recipient MSISDN.
Flood Threshold 1	Select to apply Flood Threshold 1 to the MSISDN exception.
Flood Threshold 2	Select to apply Flood Threshold 2 to the MSISDN exception.
Flood Threshold 3	Select to apply Flood Threshold 3 to the MSISDN exception.
Duplicate Threshold 1	Select to apply Duplicate Threshold 1 to the MSISDN exception.
Duplicate Threshold 2	Select to apply Duplicate Threshold 2 to the MSISDN exception.
Duplicate Threshold 3	Select to apply Duplicate Threshold 3 to the MSISDN exception.

MMS Address Translation options

The sender's carrier endpoint is used to provide logging and reporting details to the mobile operator and to identify the sender of infected content.

When MMS messages are transmitted, the **From** field may or may not contain the sender's address. When the address is not included, the sender information will not be present in the logs and the unit will not be able to notify the user if the message is blocked unless the sender's address is made available elsewhere in the request.

The unit can extract the sender's address from an extended HTTP header field in the HTTP request. This field must be added to the HTTP request before it is received by the unit. If this field is present, it will be used instead of the sender's address in the MMS message for logging and notification. If this header field is present when a message is retrieved, it will be used instead of the **To** address in the message. If this header field is not present the content of the **To** header field is used instead.

Alternatively, the unit can extract the sender's address from a cookie.

You can configure MMS address translation to extract the sender's carrier endpoint so that it can be added to log and notification messages. You can configure MMS address translation settings to extract carrier endpoints from HTTP header fields or from cookies. You can also configure MMS address translation to add an endpoint prefix to

the extracted carrier endpoints. For more information, see Dynamic Profiles and Endpoints in the Authentication guide.

MMS Address Translation

Sender Address Source

Select to extract the sender's address from the **HTTP Header Field** or a **Cookie**. You must also specify the identifier that contains the carrier endpoint.

Enter the sender address identifier that includes the carrier endpoint. The default identifier is `x-up-calling-line-id`.

If the **Sender Address Source** is **HTTP Header Field**, the address and its identifier in the HTTP request header takes the format:

```
<Sender Address Identifier>: <MSISDN_value>
```

Where the `<MSISDN_value>` is the carrier endpoint. For example, the HTTP header might contain:

```
x-up-calling-line-id: 6044301297
```

where `x-up-calling-line-id` would be the Sender Address Identifier.

Sender Address Identifier

If the **Sender Address Source** is **Cookie**, the address and its identifier in the HTTP request header's `Cookie` field takes the format of attribute-value pairs:

```
Cookie: id=<cookie-id>;
```

```
<Sender Address Identifier>=<MSISDN Value>
```

For example, the HTTP request headers might contain:

```
Cookie: id=0123jff!a;x-up-calling-line-id=6044301297
```

where `x-up-calling-line-id` would be the **Sender Address Identifier**.

Convert Sender Address From / To HEX

Select to convert the sender address from ASCII to hexadecimal or from hexadecimal to ASCII. This is required by some applications.

Add Carrier Endpoint Prefix for Logging / Notification

Select the following to enable adding endpoint prefixes for logging and notification.

Enable

Select to enable adding the country code to the extracted carrier endpoint, such as the MSISDN, for logging and notification purposes. You can limit the number length for the test numbers used for internal monitoring without a country code.

MMS Address Translation

Prefix	Enter a carrier endpoint prefix to be added to all carrier endpoints. Use the prefix to add extra information to the carrier endpoint in the log entry.
Minimum Length	Enter the minimum length of the country code information being added. If this and Maximum Length are set to zero (0), length is not limited.
Maximum Length	Enter the maximum length of the country code information being added. If this and Minimum Length are set to zero (0), length is not limited.

MMS Notifications

MMS notifications are messages that a unit sends when an MMS profile matches content in an MM1, MM3, MM4 or MM7 session. For example, the MMS profile detects a virus or uses content blocking to block a web page, text message or email. You can send notifications to the sender of the message using same protocol and the addressing headers in the original message. You can also configure MMS notifications to send notification messages to another destination (such as a system administrator) using the MM1, MM3, MM4 or MM7 protocol.

You need to enable one or more **Notification Types** or you can add an **Antivirus Notification List** to enable sending notifications.

You can also use MMS notifications options to configure how often notifications are sent. The unit sends notification messages immediately for the first event, then at a configurable interval if events continue to occur. If the interval does not coincide with the window of time during which notices may be sent, the unit waits to send the notice in the next available window. Subsequent notices contain a count of the number of events that have occurred since the previous notification.

There are separate notifications for each notification type, including virus events. Virus event notifications include the virus name. Up to three viruses are tracked for each user at a time. If a fourth virus is found, one of the existing tracked viruses is removed from the list.

The notifications are MM1 `m-send-req` messages sent from the unit directly to the MMSC for delivery to the client. The host name of the MMSC, the URL to which `m-send-req` messages are sent, and the port must be specified.

MMS Notification

Antivirus Notification List	<p>Optionally select an antivirus notification list to select a list of virus names to send notifications for. The unit sends a notification message whenever a virus name or prefix in the antivirus notification list matches the name of a virus detected in a session scanned by the MMS protection profile. Select Disabled if you do not want to use a notification list.</p> <p>Instead of selecting a notification list you can configure the Virus ScanNotification Type to send notifications for all viruses.</p>
------------------------------------	--

MMS Notification

Message Protocol	<p>In each column, select the protocol used to send notification messages. You can use a different protocol to send the notification message than the protocol on which the violation was sent. The MMS Notifications options change depending on the message protocol that you select.</p> <p>If you select a different message protocol, you must also enter the User Domain. If selecting MM7 you must also enter the Message Type.</p>
Message Type	Select the MM7 message type to use if sending notifications using MM7. Options include deliver.REQ and submit.REQ
Detect Server Details	<p>Select to use the information in the headers of the original message to set the address of the notification message. If you do not select this option, you can enter the required addressing information manually.</p> <p>You cannot select Detect Server Details if you are sending notification messages using a different message protocol.</p> <p>If you select Detect Server Details, you cannot change the Port where the notification is being sent.</p>
Hostname	Enter the FQDN or the IP address of the server where the notifications will be sent.
URL	<p>Enter the URL of the server. For example if the notification is going to www.example.com/home/alerts , the URL is /home/alerts.</p> <p>This option is available only when Message Protocol is mm1 or mm7.</p>
Port	<p>Enter the port number of the server.</p> <p>You cannot change the Port if Detect Server Details is enabled.</p>
Username	<p>Enter the user name required for sending messages using this server (optional).</p> <p>This option is available only when Message Protocol is mm7.</p>
Password	<p>Enter the password required for sending messages using this server (optional).</p> <p>This option is available only when Message Protocol is mm7.</p>

MMS Notification	
VASP ID	<p>Enter the value-added-service-provider (VASP) ID to be used when sending a notification message. If a VAS is not offered by the mobile provider, it is offered by a third party or a VAS provider or content provider (CP).</p> <p>This option is available only when Message Protocol is mm7.</p>
VAS ID	<p>Enter the value-added-service (VAS) ID to be used when sending a notification message. A VAS is generally any service beyond voice calls and fax.</p> <p>This option is available only when Message Protocol is mm7.</p>
All Notification Types	<p>In each column, select notification for all MMS event types for that MMS protocol, then enter the amount of time and select the time unit for notice intervals.</p> <p>Alternatively, expand All Notification Types, and then select notification for individual MMS event types for each MMS protocol. Then enter the amount of time and select the time unit for notice intervals.</p> <p>Not all event types are available for all MMS protocols.</p>
Content Filter	In each column, select to notify when messages are blocked by the content filter, then enter the amount of time and select the time unit for notice intervals.
File Block	In each column, select to notify when messages are blocked by file block, then enter the amount of time and select the time unit for notice intervals.
Carrier Endpoint Block	In each column, select to notify when messages are blocked, then enter the amount of time and select the time unit for notice intervals.
Flood	In each column, select to notify when message flood events occur, then enter the amount of time and select the time unit for notice intervals.
Duplicate	In each column, select to notify when duplicate message events occur, then enter the amount of time and select the time unit for notice intervals.
MMS Content Checksum	In each column, select to notify when the content within an MMS message is scanned and banned because of the checksum value that was matched.
Virus Scan	In each column, select to notify when the content within an MMS message is scanned for viruses.

MMS Notification	
Notifications Per Second Limit	For each MMS protocol, enter the number of notifications to send per second. If you enter zero (0) , the notification rate is not limited.
Day of Week	For each MMS protocol, select the days of the week the unit is allowed to send notifications.
Window Start Time	For each MMS protocol, select the time of day to begin the message alert window. By default, the message window starts at 00:00. You can change this if you want to start the message window later in the day. When configured, notification outside this window will not be sent.
Window Duration	For each MMS protocol, select the time of day at which to end the message alert window. By default, the message window ends at 00:24. You can change this if you want to end the message window earlier in the day. When configured, notification outside this window will not be sent

DLP Archive options

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. In addition to the MMS profile's DLP archive options, you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Profile

The unit only allows one sixteenth of its memory for transferring content archive files. For example, for units with 128 MB RAM, only 8 MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

DLP Archive	
Display DLP meta-information on the system dashboard	Select each required protocol to display the content archive summary in the Log and Archive Statistics dashboard widget on the System Dashboard.

DLP Archive

Archive to FortiAnalyzer/FortiGuard	Select the type of archiving that you want for the protocol (MM1, MM3, MM4, and MM7). You can choose from Full, Summary or None.
	None — Do not send content archives.
	Summary — Send content archive metadata only. Includes information such as date and time, source and destination, request and response size, and scan result.
	<p>Full — Send content archive both metadata and copies of files or messages.</p> <p>In some cases, FortiOS Carrier may not archive content, or may make only a partial content archive, regardless of your selected option. This behavior varies by prerequisites for each protocol.</p> <p>This option is available only if a FortiAnalyzer unit or FortiGuard Analysis and Management Service is configured.</p>

Logging

You can enable logging in an MMS profile to write event log messages when the MMS profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS profile logging options to write an event log message every time a virus is detected.

You must first configure how the unit stores log messages so that you can then record these logs messages. For more information, see the FortiOS Handbook Logging and Reporting guide.

Logging

MMS-Antivirus	If antivirus settings are enabled for this MMS profile, select the following options to record Antivirus Log messages.
Viruses	Record a log message when this MMS profile detects a virus.
Blocked Files	Record a log message when antivirus file filtering enabled in this MMS profile blocks a file.
Oversized Files/Emails	Record a log message when this MMS profile encounters an oversized file or email message. Oversized files and email messages cannot be scanned for viruses.
MMS Scanning	If MMS scanning settings are enabled for this MMS profile, select the following options to record Email Filter Log messages.
Notification Messages	Select to log the number of MMS notification messages sent.

Logging	
Bulk Messages	Select to log MMS Bulk AntiSpam events. You must also select which protocols to write log messages for in the MMS bulk email filtering part of the MMS profile.
Carrier Endpoint Filter Block	Select to log MMS carrier endpoint filter events, such as MSISDN filtering.
MMS Content Checksum	Select to log MMS content checksum activity.
Content Block	Select to log content blocking events.

MMS Content Checksum

The MMS Content Checksum menu allows you to configure content checksum lists.

Configure MMS content checksum lists in **Security Profiles > MMS Content Checksum** using the following table.

MMS Content Checksum	
Lists each individual content checksum list that you created. On this page, you can edit, delete or create a content checksum list.	
Create New	Creates a new MMS content checksum list. When you select Create New , you are automatically redirected to the New List. This page provides a name field and comment field. You must enter a name to go to MMS Content Checksum Settings page.
Edit	Modifies settings to a MMS content checksum. When you select Edit , you are automatically redirected to the MMS Content Checksum Settings page.
Delete	Removes an MMS content checksum from the page.
	To remove multiple content checksum lists from within the list, on the MMS Content Checksum page, in each of the rows of the content checksum lists you want removed, select the check box and then select Delete .
	To remove all content checksum lists from list, on the MMS Content Checksum page, select the check box in the check box column and then select Delete .
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in the content checksum list.

MMS Profiles	The MMS profile or profiles that have the MMS content checksum list applied. For example if two different MMS profiles use this content checksum list, they will both be listed here.
Comments	A description given to the MMS content checksum.
Ref.	<p>Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (Security Profiles > AntiVirus > Profiles), 1 appears in Ref. .</p> <p>To view the location of the referenced object, select the number in Ref., and the Object Usage window appears displaying the various locations of the referenced object.</p> <p>To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:</p> <ul style="list-style-type: none"> • View the list page for these objects – automatically redirects you to the list page where the object is referenced at. • Edit this object – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • View the details for this object – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Notification List

The Notification List menu allows you to configure a list of viruses. This virus list provides a list for scanning viruses in MMS messages. You can use one virus list in multiple MMS profiles, and configure multiple virus lists.

Notification list configuration settings

The following are notification list configuration settings in **Security Profiles > Notification List**.

Notification List	Lists all the notification lists that you created. On this page you can edit, delete or create a new notification list.
Create New	Creates a new notification list. When you select Create New , you are automatically redirected to the New List page. You must enter a name to go to the Notification List Settings page.

Edit	Modifies settings within the notification list. When you select Edit , you are automatically redirected to the Notification List Settings page.
Delete	<p>Removes a notification list from the list on the Notification List page.</p> <p>To remove multiple notification lists from within the list, on the Notification List page, in each of the rows of the notification lists you want removed, select the check box and then select Delete.</p> <p>To remove all notification lists from the list, on the Notification List page, select the check box in the check box column and then select Delete.</p>
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in that content checksum list.
MMS Profiles	The MMS profile or profiles that are associated with
Comments	A description given to the MMS notification list.
Ref.	<p>Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (Security Profiles > Antivirus > Profiles), 1 appears in Ref. .</p> <p>To view the location of the referenced object, select the number in Ref., and the Object Usage window appears displaying the various locations of the referenced object.</p> <p>To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:</p> <ul style="list-style-type: none"> • View the list page for these objects – automatically redirects you to the list page where the object is referenced at. • Edit this object – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • View the details for this object – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Notification List Settings	
Provides settings for configuring a notification list, which is a list of viruses and is used for scanning viruses in MMS messages. This list is called the Antivirus Notification List in an MMS profile.	

Name	If editing the name of a notification list, enter the new name in this field. You must select OK to save the change.
Comments	If you want to enter a comment, enter the comment in the field. You must select OK to save the change.
Create New	Creates a notification entry in the list. When you select Create New , you are automatically redirected to the New Entry page.
Edit	Modifies settings within a notification list. When you select Edit , you are automatically redirected to the Edit Entry page.
Delete	Removes a notification entry from the list on the page. To remove multiple notification entries from within the list, on the Notification List Settings page, in each of the rows of the entries you want removed, select the check box and then select Delete . To remove all notification entries from the list, on the Notification List Settings page, select the check box in the check box column and then select Delete .
Enable	Enables a notification entry that is disabled.
Disable	Disables a notification entry so that it is not active and available for use, but it is not deleted.
Remove All Entries	Removes all notification entries that are listed on the Notification List Settings page.
Enable	Displays whether or not the checksum is enabled.
Virus Name/Profile	The name of the virus that was added to the list.
Entry Type	The type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
New Entry page	
Virus Name/Profile	Enter the virus name.
Entry Type	Select the type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
Enable	Select to enable the virus in the list.

Message Flood

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse. A

message flood occurs when a single subscriber sends a volume of messages that exceed the flood threshold that you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected. For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all outgoing messages blocked for 30 minutes.

Action	Description
Log	Add a log entry indicating that a message flood has occurred. You must also enable logging by going to Security Profiles > MMS Profile , <applicable profile> > Logging > MMS Scanning > Bulk Messages , and toggling on the checkbox.
DLP Archive	Save the first message to exceed the flood threshold, or all the messages that exceed the flood threshold, in the DLP archive. DLP archiving flood messages may not always produce useful results. Since different messages can be causing the flood, reviewing the archived messages may not be a good indication of what is causing the problem since the messages could be completely random.
All messages	All the messages that exceed the flood threshold will be saved in the DLP archive.
First message only	Save only the first message to exceed the flood threshold in the DLP archive. Other messages in the flood are not saved. For message floods this may not produce much useful information since a legitimate message could trigger the flood threshold.
Intercept	Messages that exceed the flood threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message will also be quarantined for later examination. If the quarantine of intercepted messages is disabled, the Intercept action has no effect.
Block	Messages that exceed the flood threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each message will be quarantined for later examination.
Alert Notification	<p>If the flood threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS flood notification message.</p> <p>In the web-based manager when Alert Notification is selected it displays the fields to configure the notification.</p>

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

Message flood configuration settings

The following are message flood configuration settings in **Security Profiles > Message Flood**.

Message Flood	
Lists the large amount of messages that are being sent to you from outside sources.	
Delete	<p>Removes messages from the list.</p> <p>To remove multiple messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select Delete.</p> <p>To remove all messages from the list, on the Message Flood page, select the check box in the check box column and then select Delete.</p>
Remove All Entries	Removes all messages from the list.
Protocol	Sorts/filters by the protocol used.
MMS Profile	Sorts/filters by the MMS profile that is used.
Sender	Sorts/filters by the sender's email address.
Level	Sorts/filters by the level of severity of the message.
Count	The count column can be up or down and these settings can be turned off by selecting beside the column's name.
Window Size (minutes)	The time in minutes.
Timer (minutes:seconds)	The time in seconds and in minutes. The timer column can be up or down and these settings turned off by selecting beside the column's name.
Page Controls	Use to navigate through the list.

Duplicate Message

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC.

The unit keeps track of the sent messages. If the same message appears more often than the threshold value that you have configured, action is taken. Possible actions are logging the duplicate messages, blocking or intercepting them, archiving, and sending an alert to inform an administrator that duplicate messages are occurring.

Duplicate message configuration settings

View duplicate messages in **Security Profiles > Duplicate Message**.

Duplicate Message

Lists duplicates of messages that were sent to you.

Delete	Removes a message from the list.
	To remove multiple duplicate messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select Delete .
	To remove all duplicate messages from the list, on the Message Flood page, select the check box in the check box column and then select Delete .
Page Controls	Use to navigate through the list.
Remove All Entries	Removes all duplicate messages from the list.
Protocol	Sorts/filters by the protocol used.
MMS Profile	Sorts/filters by the MMS profile that logs the detection.
Checksum	Sorts/filters by the checksum of the MMS message.
Level	Sorts/filters by the level of severity of the message.
Count	Displays the number of messages in the last window of time.
Window Size (minutes)	The period of time during which a message flood will be detected if the Message Flood Limit is exceeded.
Timer (minutes:seconds)	Either the time left in the window if the message is unflagged, or the time until the message will be unflagged if it is already flagged.

Carrier Endpoint Filter Lists

A carrier endpoint filter list contains carrier endpoint patterns. A pattern can match one carrier endpoint or can use wildcards or regular expressions to match multiple carrier endpoints. For each pattern, you select the action that the unit takes on a message when the pattern matches a carrier endpoint in the message. Actions include blocking the message, exempting the message from MMS scanning, and exempting the message from all scanning. You can also configure the pattern to intercept the message and content archive the message to a FortiAnalyzer unit.

Carrier endpoint filter lists configuration settings

The following are Carrier endpoint filter list configuration settings in **Security Profiles > Carrier Endpoint Filter Lists**.

Carrier Endpoint Filter Lists

Lists all the endpoint filters that you created. On this page, you can edit, delete or create a new endpoint filter list.

Create New	Creates a new endpoint filter list. When you select Create New , you are automatically redirected to the New List page. You must enter a name to go to the Carrier Endpoint Filter Lists Settings page.
Edit	Modifies settings within an endpoint filter list in the list.
Delete	<p>Removes an endpoint filter in the list.</p> <p>To remove multiple endpoint filter lists from within the list, on the Carrier Endpoint Filter List page, in each of the rows of the endpoint filter lists you want removed, select the check box and then select Delete.</p> <p>To remove all endpoint filter lists from the list, on the Carrier Endpoint Filter List page, select the check box in the check box column and then select Delete.</p>
Name	The name of the endpoint filter.
# Entries	The number of carrier endpoint patterns in each carrier endpoint filter list.
MMS Profiles	The MMS profile that the carrier endpoint filter list is added to.
Comments	A description about the endpoint filter.

Ref.	<p>Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (Security Profiles > Antivirus > Profiles), 1 appears in Ref. .</p> <p>To view the location of the referenced object, select the number in Ref., and the Object Usage window appears displaying the various locations of the referenced object.</p> <p>To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:</p> <ul style="list-style-type: none"> • View the list page for these objects – automatically redirects you to the list page where the object is referenced at. • Edit this object – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • View the details for this object – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
-------------	---

Carrier Endpoint Filter Lists Settings

Provides settings for configuring an endpoint filter.

Name	The name you entered on the New List page, after selecting Create New on the Carrier Endpoint Filter page.
Comments	A description about the endpoint filter. You can add one here if you did not enter one on the New List page.
Create New	Creates a new endpoint filter list. When you select Create New , you are automatically redirected to the New Entry page.
Edit	Select to modify the settings of a pattern in the list.
Delete	Select to remove a pattern in the list.
Enable	Enables a disabled pattern in the list.
Disable	Disables a pattern in the list.
Remove All Entries	Removes all patterns in the list on the Carrier Endpoint Filter Lists Settings page.
Enable	Indicates whether or not the pattern is enabled.

Pattern	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set Pattern Type to correspond to the pattern that you want to use.
Action	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
Pattern Type	The type of pattern chosen.
New Entry page	
Pattern	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set Pattern Type to correspond to the pattern that you want to use.
Action(s)	<p>Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:</p> <p>Action(s) can be:</p> <ul style="list-style-type: none"> • None • Block • Exempt from mass MMS • Exempt from all scanning
Content Archive	MMS messages from the carrier endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Pattern Type	<p>Select a pattern type as one of Single Carrier Endpoint, Wildcard or Regular Expression.</p> <p>Wildcard and Regular Expression will match multiple patterns where Single Carrier Endpoint matches only one.</p>
Enable	Select to enable this carrier endpoint filter pattern.

Message flood protection

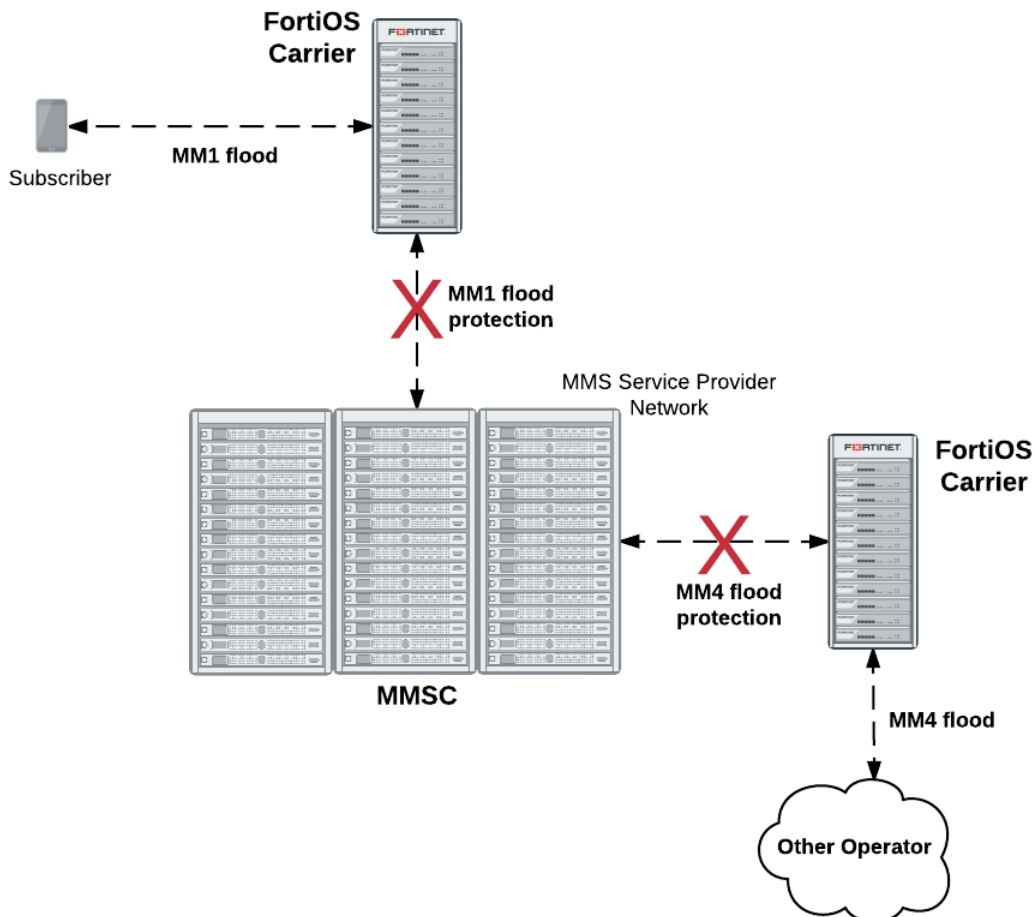

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse.

Overview

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many

messages from the same subscriber to your MMSC.

MM1 and MM4 flood protection

The FortiOS Carrier unit keeps track of the number of messages each subscriber sends for the length of time you specify. If the number of messages a subscriber sends exceeds the threshold, a configured action is taken. Possible actions are logging the flood, blocking or intercepting messages in the flood, archiving the flood messages, and sending an alert message to inform the administrator that the flood is occurring.

You can create three different thresholds to take different levels of action at different levels of activity.

With this highly configurable system, you can prevent subscribers from sending more messages than you determine is acceptable, or monitor anyone who exceeds the thresholds.

Setting message flood thresholds

A message flood occurs when a single subscriber sends a volume of messages that exceeds the flood threshold you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected.

If a subscriber exceeds the message flood threshold and is blocked from sending more messages, any further attempts to send messages will re-start the block period. You must also enable logging for **MMS Scanning > Bulk Messages** in the Logging section of the MMS protection profile.

A subscriber is still able to receive messages while they are blocked from sending messages.

Example

For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all messages blocked for half an hour (30 minutes).

Using this example, if the subscriber exceeds the flood threshold, they are blocked from sending message for 30 minutes. If the subscriber tries to send any message after 15 minutes, the message will be blocked and the block period will be reset again to 30 minutes. The block period must expire with no attempts to send a message. Only then will the subscriber be allowed to send more messages.

To configure MM1 message flood threshold - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New**.
3. Enter `MM1 flood` for **Profile Name**.
4. Expand **MMS Bulk Email Filtering Detection**.
5. Enter the following information, and select **OK**.

MM1 (first column)	
Enable	Enable
Message Flood Window	60 minutes
Message Flood Limit	100
Message Flood Block Time	30 minutes
Message Flood Action	Block

To configure MM1 message flood threshold - CLI

```
config firewall mms-profile
edit profile_name
config flood mm1
set status1 enable
set window1 60
set limit1 100
set action1 block
set block-time1 30
end
end
```

The threshold values that you set for your network will depend on factors such as how busy your network is and the kinds of problems that your network and your subscribers encounter. For example, if your network is not too busy you may want to set message flood thresholds relatively high so that only an exceptional situation will exceed a flood threshold. Then you can use log messages and archived MMS messages to determine what caused the flood.

If your subscribers are experiencing problems with viruses that send excessive amounts of messages, you may want to set thresholds lower and enable blocking to catch problems as quickly as possible and block access to keep the problem from spreading.

Flood actions

When the Carrier-enabled FortiGate unit detects a message flood, it can take any combination of the five actions that you can configure for the flood threshold. For detailed options, see Message Flood.

Notifying administrators of floods

You can configure alert notifications for message floods by selecting the Alert Notification message flood action.

The FortiOS Carrier unit sends alert notifications to administrators using the MM1, MM3, MM4, or MM7 content interface. To send an alert notification you must configure addresses and other settings required for the content interface.

For example, to send notifications using the MM1 content interface you must configure a source MSISDN, hostname, URL, and port to which to send the notification. You can also configure schedules for when to send the notifications.

Finally you can add multiple MSISDN numbers to the MMS protection profile and set which flood thresholds to send to each MSISDN.

Example — three flood threshold levels with different actions for each threshold

You can set up to three threshold levels to take different actions at different levels of activity.

The first example threshold records log messages when a subscriber's handset displays erratic behavior by sending multiple messages using MM1 at a relatively low threshold. The erratic behavior could indicate a problem with the subscriber's handset. For example, you may have determined for your network that if a subscriber sends more the 45 messages in 30 minutes that you want to record log messages as a possible indication or erratic behavior.

From the web-based manager in an MMS profile set message **Flood Threshold 1** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	45
Message Flood Action	Log

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config flood mm1
```

```

        set status1 enable
        set window1 30
        set limit1 45
        set action1 log
    end
end

```

Set a second higher threshold to take additional actions when a subscriber sends more that 100 messages in 30 minutes. Set the actions for this threshold to log the flood, archive the message that triggered the second threshold, and block the sender for 15 minutes.

From the web-based manager in an MMS profile set message **Flood Threshold 2** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	100
Message Block Time	15 minutes
Message Flood Action	Log, DLP archive First message only, Block

From the CLI:

```

config firewall mms-profile
  edit profile_name
    config flood mm1
      set status2 enable
      set window2 30
      set limit2 100
      set action2 block log archive-first
      set block-time2 15
    end
  end
end

```

Set the third and highest threshold to block the subscriber for an extended period and sand an administrator alert if the subscriber sends more than 200 messages in 30 minutes. Set the actions for this threshold to block the sender for four hours (240 minutes), log the flood, archive the message that triggered the third threshold, and send an alert to the administrator.

From the web-based manager in an MMS profile set message **Flood Threshold 3** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	200
Message Block Time	240 minutes
Message Flood Action	Log, Block, Alert Notification

Because you have selected the **Alert Notification** action you must also configure alert notification settings. For this example, the source MSISDN is 5551234—telephone number 555-1234. When administrators receive MMS messages from this MSISDN they can assume a message flood has been detected.

In this example, alert notifications are sent by the FortiOS Carrier unit to the MMSC using MM1. The host name of the MMSC is `mmscexample`, the MMSC URL is `/`, and the port used by the MMSC is 80. In this example, the alert notification window starts at 8:00am and extends for eight hours on weekdays (Monday-Friday) and the minimum interval between message flood notifications is two hours.

Source MSISDN	5551234
Message Protocol	MM1
Hostname	mmscexample
URL	/
Port	80
Notifications Per Second Limit	0
Window Start Time	8:00
Window Duration	8:00
Day of Week	Mon, Tue, Wed, Thu, Fri, Sat
Interval	2 hours

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notification alert-flood-1
      set alert-src-msisdn 5551234
      set msg-protocol mm1
      set mmsc-hostname mmscexample
      set mmsc-url /
      set mmsc-port 80
      set rate-limit 0
      set tod-window-start 8:00
      set tod-window-duration 8:00
      set days-allowed monday tuesday wednesday thursday friday
      set alert-int 2
      set alert-int-mode hours
    end
```

You must also add the MSISDNs of the administrators to be notified of the message flood. In this example, the administrator flood threshold 3 alert notifications are sent to one administrator with MSISDN 5554321.

To add administrator's MSISDNs for flood threshold 3 from the web-based manager when configuring a protection profile, select **MMS Bulk Email Filtering Detection > Recipient MSISDN > Create New**.

MSISDN	5554321
Flood Level 3	Select

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notif-msisdn
      edit 5554321
        set threshold flood-thresh-3
      end
    end
  end
```

Notifying message flood senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver that cause a message flood. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around flood protection. For this reason, no notification is set to the sender or receiver.

However, FortiOS Carrier does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as message floods. For information about how FortiOS Carrier responds when message flood detection blocks a message, see and MMS duplicate messages and message floods.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (`m-send.conf`) to the sender — otherwise the sender's handset would keep retrying the message. The `m-send.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the MMSC and the MMSC sends the `m-send.conf` message.

You can customize the `m-send.conf` message by editing the **MM1 send-conf flood message** MM1 replacement message (from the CLI the `mm1-send-conf-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that FortiOS Carrier is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK":

```
config system replacemsg mm1 mm1-send-conf-flood
  set rsp-status ok
  set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (`m-retrieve.conf`) to the sender (otherwise the sender's handset would keep retrying the message). The `m-retrieve.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the receiver, so the MMSC sends the `m-retrieve.conf` message.

You can customize the m-retrieve.conf message by editing the **MM1 retrieve-conf flood message** MM1 replacement message (from the CLI the `mm1-retr-conf-flood` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-flood
    set subject "Message blocked"
    set message "Message temporarily blocked by carrier"
end
```

Forward responses for MM4 message floods

When the FortiOS Carrier unit identifies an MM4 message as a flood message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 message flood action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4_forward.res message by editing the **MM4 flood message** MM4 replacement message (from the CLI the `mm4-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK" for the MM4 message forward response

```
config system replacemsg mm4 mm4-flood
    set rsp-status ok
    set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If **DLP Archive** is a selected message flood action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages, but you can configure the DLP archive setting to save only the first message that exceeds the threshold. This still provides a sample of the offending messages without requiring as much storage.

To select only the first message in a flood for DLP archiving - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Edit an existing MMS Profile.
3. Expand the **MMS Bulk Email Filtering Detection** section, the **Message Flood** subsection, and the desired **Flood Threshold** subsection.
4. Next to **DLP Archive**, select **First message only** from the drop down menu.
5. Select **OK**.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totaling the number of messages sent by each subscriber regardless

of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

Bypassing message flood protection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from message flood protection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns.

If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass message flood protection. This allows legitimate bulk messages, such as system outage notifications, to be delivered without triggering message flood protection.

For more information on carrier endpoints, see the User Authentication chapter of the FortiOS Handbook.

Configuring message flood detection

To have the Carrier-enabled FortiGate unit check for message floods, you must first configure the flood threshold in an MMS profile, select the MMS profile in a security policy. All the traffic examined by the security policy will be checked for message floods according to the threshold values you set in the MMS profile.

Configure the MMS profile - web-based manager

1. Go to **Firewall Objects > MMS Profile**.
2. If you are editing an MMS profile, select the **Edit** icon of the MMS profile.
If you are creating a new MMS profile, select **Create New** and enter a profile name.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Message Flood**.
5. Expand **Flood Threshold 1**.
6. Select the **Enable** check box for MM1 messages, MM4 messages, or both.
7. In the **Message Flood Window** field, enter the length of time the Carrier-enabled FortiGate unit will keep track of the number of messages each subscriber sends.
If the Carrier-enabled FortiGate unit detects the quantity of messages specified in the **Message Flood Limit** sent during the number of minutes specified in the **Message Flood Window**, a message flood is in progress.
8. In the **Message Flood Limit** field, enter the number of messages required to trigger the flood.
9. In the **Message Flood Block Time** field, enter the length of time a user will be blocked from sending messages after causing the message flood.
10. Select the message flood actions the Carrier-enabled FortiGate unit will take when the message flood is detected.
11. Select **OK**.

Configure the security policy - web-based manager

1. Go to **Policy**.
2. Select the **Edit** icon of the security policy that controls the traffic in which you want to detect message floods.
3. Select the **MMS Profile** check box to enable the use of a protection profile.
4. Select the MMS protection profile from the list.
5. Select **OK**.

Sending administrator alert notifications

When message floods are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the message flood action. Each message flood threshold can be configured separately.

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 message floods. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- **submit.REQ** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- **deliver.REQ** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

For more information, see MMS notifications.

To configure administrator alert notifications - web-based manager

1. Go to **Firewall Objects > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.
There are three message flood thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Message Flood Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.
Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.
By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.
10. For **Day of Week**, select the days of the week to send notifications.
For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.
All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the message flood threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to **Firewall Objects > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for flood threshold alert notification.
7. Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the flood threshold to be able to send an alert notification to the MSISDN, the alert notification action must be enabled and configured within the flood threshold.

Duplicate message protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or other unwanted messages. Often, the same message will be sent by multiple subscribers. The message can be spam, viral marketing, or worm-generated messages. MMS duplicate prevention can help prevent this type of abuse by keeping track of the messages being sent.

Overview

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC. This can help prevent a potential flood that would otherwise become widespread between carriers.

MM1 and MM4 duplicate message protection

The FortiOS Carrier unit keeps track of the sent messages. If the same message appears more often than the threshold value you configure, then action is taken. Possible actions are logging the duplicates, blocking or intercepting duplicate messages, archiving the duplicate messages, and sending an alert to inform an administrator that duplicates are occurring.

With this highly configurable system, you can prevent the transmission of duplicate messages when there are more than you determine is acceptable.

For detailed configuration options, see [Duplicate Message](#).

Using message fingerprints to identify duplicate messages

The Carrier-enabled FortiGate unit detects duplicates by keeping a record of all the messages travelling on the network and comparing new messages to those that have already been sent.

Rather than save the messages, the FortiOS carrier creates a checksum using the message body and subject. This serves as a fingerprint to identify the message. If another message with the same message body and subject appears, the fingerprint will also be the same and the Carrier-enabled FortiGate unit will recognize it as a duplicate.

By creating and saving message fingerprints instead of saving the messages, the Carrier-enabled FortiGate unit can save resources and time.

Messages from any sender to any recipient

Duplicate message detection will detect duplicate messages regardless of the sender or recipient. To do this, message fingerprints are generated using only the message body and subject. The sender, recipient, and other header information is not included.

If multiple messages appear with the same subject and message body, the Carrier-enabled FortiGate unit will recognize them as being the same.

Setting duplicate message thresholds

The FortiOS Carrier recognizes all duplicate messages, but it will take action when it detects a volume of duplicate messages that exceed the duplicate threshold you set. The threshold defines the maximum number of duplicate messages allowed, the period during which the messages are considered, and the length of time the duplicate message can not be sent by anyone.

For example, you may determine that once a duplicate message is sent more than 300 times in an hour, any attempt to send the same duplicate message will be blocked for 30 minutes.

If a particular duplicate message exceeds the duplicate message threshold and is blocked, any further attempts to send the same message will re-start the block period.

Using the example above, if the duplicate message count exceeds the duplicate threshold, any attempt to send a copy of the duplicate message will be blocked for 30 minutes. If a subscriber tries to send a copy of the message after waiting 15 minutes, the message will be blocked and the block period will be reset to 30 minutes. The block period must expire with no attempts to send a duplicate message. Only then will a subscriber be allowed to send the message. Non-duplicate messages will not reset the block period.

Duplicate message actions

When the Carrier-enabled FortiGate unit detects that a duplicate message has exceeded duplicate threshold, it can take any combination of the five actions you configure for the duplicate threshold.

Action	Description
Log	Add a log entry indicating that a duplicate message event has occurred. You must also enable logging for MMS Scanning > Bulk Messages in the Logging section of the MMS protection profile.
DLP Archive	

Action	Description
All messages	Save all the messages that exceed the duplicate threshold in the DLP archive.
First message only	Save the first message to exceed the duplicate threshold in the DLP archive. Subsequent messages that exceed the duplicate threshold will not be saved.
Intercept	Messages that exceed the duplicate threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message is also quarantined for later examination. If the quarantine of intercepted messages is disabled, the Intercept action has no effect.
Block	Messages that exceed the duplicate threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each blocked message is quarantined for later examination.
Alert Notification	If the duplicate threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS duplicate message notification message.

Notifying duplicate message senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver of duplicate messages. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around duplicate message protection. For this reason, no notification is set to the sender or receiver.

However, the FortiOS Carrier unit does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as duplicate messages. For information about how FortiOS Carrier responds when message flood detection blocks a message, see and MMS duplicate messages and message floods.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (m-send.conf) to the sender (otherwise the sender's handset would keep retrying the message). The m-send.conf message is sent only when the MM1 duplicate message action is set to Block. For other duplicate message actions the message is actually delivered to the MMSC and the MMSC sends the m-send.conf message.

You can customize the m-send.conf message by editing the **MM1 send-conf duplicate message** MM1 replacement message (from the CLI the `mm1-send-conf-dupe` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK":

```
config system replacemsg mm1 mm1-send-conf-dupe
    set rsp-status ok
    set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender's handset would keep retrying). The m-retrieve.conf message is sent only when the MM1duplicate message action is set to Block. For other message flood actions the message is actually received by the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrieve.conf message by editing the **MM1 retrieve-conf duplicate message** MM1 replacement message (from the CLI the mm1-retr-conf-dupe replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-dupe
    set subject "Message blocked"
    set message "Message temporarily blocked by carrier"
end
```

Forward responses for duplicate MM4 messages

When the FortiOS Carrier unit identifies an MM4 message as a duplicate message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 duplicate message action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4_forward.res message by editing the **MM4 duplicate message** MM4 replacement message (from the CLI the mm4-dupe replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (err-content-not-accept). To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Forwarded OK":

```
config system replacemsg mm4 mm4-dupe
    set rsp-status ok
    set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If **DLP Archive** is a selected duplicate message action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages but you can configure the DLP archive setting to save only the first message that exceeds the threshold. See Viewing DLP archived messages.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber

regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

Bypassing duplicate message detection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from duplicate message detection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass duplicate message detection. For more information about endpoints, see FortiOS Handbook User Authentication guide.

Configuring duplicate message detection

To have the Carrier-enabled FortiGate unit check for duplicate messages, configure the duplicate threshold in an MMS profile, and select the MMS profile in a security policy.

All traffic matching the security policy will be checked for duplicate messages according to the settings in the MMS profile.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

The modular nature of the profiles allows you great flexibility in how you configure the scanning options. MMS profiles can be used in any number of policies, with different GTP profiles.

In a complex configuration, there may be many security policies, each with a different MMS profile. For a simpler network, you may have many security policies all using the same MMS profile.

Sending administrator alert notifications

When duplicate messages are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the duplicate message action. Each duplicate message threshold can be configured separately.

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 duplicate messages. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- **submit.REQ** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- **deliver.REQ** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

To configure administrator alert notifications - web-based manager

1. Go to **Security Profiles > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.
There are three duplicate message thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Duplicate Message Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.
Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.
By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.
10. For **Day of Week**, select the days of the week to send notifications.
For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.

All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the duplicate threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for duplicate threshold alert notification.

Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the duplicate threshold to be able to send an alert notification to the MSISDN, the duplicate message threshold alert notification action must be enabled and configured.

Employing MMS Security features

FortiOS Carrier includes all the Security features of FortiOS with extra features specific to MMS carrier networks.

This section includes:

Why scan MMS messages for viruses and malware?

The requirement for scanning MM1 content comes from the fact that MMS is an increasingly popular technique for propagating malware between mobile devices.

Example: COMMWARRIOR

This is a virus for Series 60 type cell phones, such as Nokia, operating Symbian OS version 6 [or higher]. The object of the virus is to spread to other phones using Bluetooth and MMS as transport avenues. The targets are selected from the contact list of the infected phone and also sought via Bluetooth searching for other Bluetooth-enabled devices (phones, printers, gaming devices etc.) in the proximity of the infected phone.

This virus is more than a proof of concept - it has proven successfully its ability to migrate from a zoo collection to being in-the-wild. Currently, this virus is being reported in over 18 different countries around Europe, Asia and North America.

When the virus first infects a cell phone, a prompt is displayed asking the recipient if they want to install "Caribe". Symptoms of an infected phone may include rapid battery power loss due to constant efforts by the virus to spread to other phones via a Bluetooth seek-and-connect outreach.

The following variants among others are currently scanned by the FortiOS Carrier devices, in addition to more signatures that cover all known threats.

- **SymbOS/COMWAR.V10B!WORM**

- Aliases: SymbOS.Commwarrior.B, SymbOS/Commwar.B, SymbOS/Commwar.B!wm, SymbOS/Commwar.B-net, SymbOS/Commwarrior.b!sis, SymbOS/Comwar.B, SymbOS/Comwar.B!wm, SymbOS/Comwar.B-wm, SYMBOS_COMWAR.B, SymbOS/Comwar.1.0.B!wormSYMBOS/COMWAR.V10B.SP!WORM [Spanish version]
- First Discovered In The Wild: July 04, 2007
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 23,320

- **SymbOS/Commwar.A!worm**

- Aliases: Commwarrior-A, SymbOS.Commwarrior.A [NAV], SymbOS/Commwar.A-net, SymbOS/Commwar_ezboot.A-ne, SymbOS/Comwar.A, SymbOS/Comwar.A-wm, SYMBOS_COMWAR.A [Trend]
- First Discovered In The Wild: May 16 2005
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 27,936
- SymbOS/Commwarriie.C-wm
- Aliases: None
- First Discovered In The Wild: Oct 17 2005
- Impact Level: 1
- Virus Class: File Virus
- Virus Name Size: None

For the latest list of threats Fortinet devices detect, visit the FortiGuard Center.

MMS virus scanning

You can use MMS virus scanning to scan content contained within MMS messages for viruses. FortiOS Carrier virus scanning can be applied to the MM1, MM3, MM4, and MM7 interfaces to detect and remove content containing viruses at many points in an MMS network. Perhaps the most useful interface to apply virus scanning would be the MM1 interface to block viruses sent by mobile users before they get into the service provider network.

To go to MMS virus scanning, go to **Security Profiles MMS Profile**, select an existing or create a new profile, and expand **MMS Scanning**. See MMS scanning options.

This section includes:

- [MMS virus monitoring](#)
- [MMS virus scanning blocks messages \(not just attachments\)](#)
- [Scanning MM1 retrieval messages](#)
- [Configuring MMS virus scanning](#)
- [Removing or replacing blocked messages](#)
- [Carrier Endpoint Block](#)
- [MMS Content Checksum](#)
- [Passing or blocking fragmented messages](#)
- [Client comforting](#)
- [Server comforting](#)
- [Handling oversized MMS messages](#)

MMS virus monitoring

To enable MMS virus monitoring, expand **MMS Scanning** and enable **Monitor only** for the selected MMS types.

This feature causes the FortiOS Carrier unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Selecting this option enables reporting on viruses and other problems in MMS traffic without affecting users.

MMS virus scanning blocks messages (not just attachments)

To enable MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan** for the selected MMS types.

Because MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configurations also apply to MM1 and MM7 scanning. See

MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configurations also apply to MM3 and MM4 scanning.

The message contents will be scanned for viruses, matched against the file extension blocking lists and scanned for banned words. All these items will be configured via the standard GUI interfaces available for the other protocols and will be controlled at the protection profile level with new options specifically for the MM1 messages.

The FortiOS Carrier unit extracts the sender's Mobile Subscriber Integrated Services Digital Network Number (MSISDN) from the HTTP headers if available. The `POST` payload will be sent to the scan units which will parse the MMS content and scan each message data section. If any part of the data is to be blocked, the proxy will be informed, the connection to the MMSC will be reset and the Carrier-enabled FortiGate unit will return an `HTTP 200 OK` message with an `m-send-conf` payload to the client to prevent a retry. Finally the appropriate logging, alert, and replacement message events will be triggered.

For client notification, the `x-mms-response-status` and `x-mms-response-text` fields can also be customized as required.

Scanning MM1 retrieval messages

To scan MM1 retrieval messages, expand **MMS Scanning** and select **Scan MM1 message retrieval**.

Select to scan message retrievals that use MM1. If you enable **Virus Scan** for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

Configuring MMS virus scanning

To configure MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan**.

Once applied to a security policy, the MMS protection profile will then perform virus scans on all traffic accepted by that policy.

Removing or replacing blocked messages

To remove blocked messages, expand **MMS Scanning** and select **Remove Blocked** for the selected MMS types.

Select **Remove Blocked** remove blocked content from each protocol and replace it with the replacement message. If FortiOS Carrier is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message, select **Constant**.

If you only want to monitor blocked content, select **Monitor Only**.

Carrier Endpoint Block

A carrier endpoint defines a specific client on the carrier network. Typically the client IP address is used to identify the client, however on a carrier network this may be impractical when the client is using a mobile device. Other identifying information such as the MSISDN number is used instead.

This information can be used to block a specific endpoint on the network. Reasons for blocking may include clients whose accounts have expired, clients from another carrier, clients who have sent malicious content (phishing, exploits, viruses, etc), or other violations of terms of use.

Enabling carrier endpoint blocking

To enable carrier endpoint blocking you first need to create a carrier endpoint filter list, and then enable it.

To enable carrier endpoint blocking - web-based manager

1. Create a carrier endpoint filter list.
2. Go to **Security Profiles > MMS Profile**.
3. Select **Create New**, or select an existing profile to edit and select **Edit**.
4. Expand MMS Scanning.
5. Select one or more types of MMS messaging to enable endpoint blocking on.
6. Select the carrier endpoint filter list to use in matching the endpoints to be blocked.

In MMS Profile, endpoints can only be blocked.

Create a carrier endpoint filter list

A carrier endpoint filter list contains one or more carrier endpoints to match. When used in MMS scanning entries in the filter list that are matched are blocked.

You can configure multiple filter lists for different purposes and groups of clients, such as blocking clients, clients with different levels of service agreements, and clients from other carriers. See Carrier endpoint filter lists configuration settings.

To create a carrier endpoint filter list - web-based manager

1. Go to **Security Profiles > Carrier Endpoint Filter Lists**.
2. Select **Create New**.
3. Enter a descriptive name for the filter list, such as `blocked_clients` or `CountryX_clients`, and select **OK**.
4. Select **Create New** to add one or more entries to the list.
5. Select **OK** to return to display the list of filter lists.

Configuring endpoint filter list entries

For each single endpoint or group of endpoints have part of their identifying information in common, you create an entry in the endpoint filter list.

For example a `blocked_clients` filter list may include entries for single endpoints added as each one needs to be blocked and a group of clients from a country that does not allow certain services.

To configure an endpoint filter list entry - web-based manager

1. Select **Create New**.
2. Enter the following information and select **OK**.

Name	Name of endpoint filter list. Select this name in an MMS protection profile.
Comments	Optional description of the endpoint filter list.
Check/Uncheck All	<p>Select the check box to enable all endpoint patterns in the MMS filter list.</p> <p>Clear the check box to disable all entries on the MMS filter list.</p> <p>You can also select or clear individual check boxes to enable or disable individual endpoint patterns.</p>
Pattern	The pattern that FortiOS Carrier uses to match with endpoints. The pattern can be a single endpoint or consist of wildcards or Perl regular expressions that will match more than one endpoint. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.
Action	<p>Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the endpoint pattern:</p> <p>None - No action is taken.</p> <p>Block - MMS messages from the endpoint are not delivered and FortiOS Carrier records a log message.</p> <p>Exempt from mass MMS - MMS messages from the endpoint are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. A valid use of mass MMS would be when a service provider notifies customers of a system-wide event such as a shutdown.</p> <p>Exempt from all scanning - MMS messages from the endpoint are delivered and are exempt from all MMS protection profile scanning.</p>

Content Archive	MMS messages from the endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Intercept	MMS messages from the endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type	The pattern type: Wildcard , Regular Expression , or Single Endpoint .
Enable	Select to enable this endpoint filter pattern.

Blocking network access based on endpoints

You can use endpoint IP filtering to block traffic from source IP addresses associated with endpoints. You can also configure FortiOS Carrier to record log messages whenever endpoint IP filtering blocks traffic. Endpoint IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy.

To configure endpoint IP filtering, go to **Security Profiles > IP Filter** and add endpoints to the IP filter list. For each endpoint you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add endpoint patterns to the endpoint IP filter list. You must enter complete and specific endpoints that are valid for your network.

The only action available is block. You cannot use endpoint IP filtering to exempt endpoints from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the endpoints in the IP filter list and extracts the source IP addresses for these endpoints. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by endpoint IP filtering.

For information about the carrier endpoints and the user context list, including how entries are added to and removed from this list.

MMS Content Checksum

The MMS content checksum feature attempts to match checksums of known malicious MMS messages, and on a successful match it will be blocked. The checksums are applied to each part of the message—attached files and message body have separate checksums. These checksums are created with CRC-32, the same method as FortiAnalyzer checksums.

For example, if an MMS message contains a browser exploit in the message body, you can add the checksum for that message body to the list, and future occurrences of that exact message will be blocked. Content will be replaced by the content checksum block notification replacement message for that type of MMS message, and if it is enabled the event will be logged.

One possible implementation would be to configure all .sis files to be intercepted. When one is found to be infected or malicious it would be added to the MMS content checksum list.

To use this feature a list of one or more malicious checksums must be created and then the feature is enabled using that list. For a detailed list of options, see MMS Content Checksum.

To configure an MMS content checksum list

1. Go to **Security Profiles > MMS Content Checksum**.
2. Select **Create New**.
3. Enter a name for the list of checksums, and select **OK**.
You are taken to the edit screen for that new list.
4. Select **Create New** to add a checksum.
5. Enter the **Name** and **Checksum**, and select **OK**.
The checksum is added to the list.

To add more checksums to the list, repeat steps 4 and 5.

To remove a checksum from the list you can either delete the checksum or simply disable it and leave it in the list.

To enable MMS content checksums, expand **MMS Scanning** and select **MMS Content Checksum** for the selected MMS types. Select the checksum list to match.

Passing or blocking fragmented messages

Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 messages are blocked.

The **Interval** is the time in seconds before client comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

Client comforting

In general, client comforting is available for MM1 and MM7 messaging and provides a visual display of progress for web page loading or HTTP or FTP file downloads. Client comforting does this by sending the first few packets of the file or web page being downloaded to the client at configured time intervals so that the client is not aware that the download has been delayed. The client is the web browser or FTP client. Without client comforting, clients and their users have no indication that the download has started until the Carrier-enabled FortiGate unit has completely buffered and scanned the download. During this delay users may cancel or repeatedly retry the transfer, thinking it has failed.

The appearance of a client comforting message (for example, a progress bar) is client-dependent. In some instances, there will be no visual client comforting cue.

During client comforting, if the file being downloaded is found to be infected, then the Carrier-enabled FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead the download stops, and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, then the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a

notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned (and therefore potentially infected) content to the client. Only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

MM1 and MM7 client comforting steps

Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.

The following steps show how client comforting works for a download of a 1 Mbyte file with the client comforting interval set to 20 seconds and the client comforting amount set to 512 bytes.

1. The client requests the file.
2. The Carrier-enabled FortiGate unit buffers the file from the server. The connection is slow, so after 20 seconds about one half of the file has been buffered.
3. The Carrier-enabled FortiGate unit continues buffering the file from the server, and also sends 512 bytes to the client.
4. After 20 more seconds, the FortiGate unit sends the next 512 bytes of the buffered file to the client.
5. When the file has been completely buffered, the client has received the following amount of data:

$$ca * (T/ci) \text{ bytes} == 512 * (40/20) == 512 * 2 == 1024 \text{ bytes,}$$
 where *ca* is the client comforting amount, *T* is the buffering time and *ci* is the client comforting interval.
6. If the file does not contain a virus, the Carrier-enabled FortiGate unit sends the rest of the file to the client. If the file is infected, the FortiGate closes the data connection but cannot send a message to the client.

Server comforting

Server comforting can be selected for each protocol.

Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for FortiOS Carrier to buffer and scan large `POST` requests from slow clients.

The **Interval** is the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

Handling oversized MMS messages

Select **Block** or **Pass** for files and email messages exceeding configured thresholds for each protocol.

The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.

```

Sender notifications and logging

In most cases you will notify the sender that they are causing problems on the network — either by sending malware content, flooding the network, or some other unwanted activity. The notification assumes the sender is unaware of their activity and will stop or correct it when notified.

However, senders who are notified may use this information to circumvent administration's precautions. For example if flood notification is set to 1000 messages per minute, a notified user may simply reduce their message to 990 messages per minute if this flood is intentional. For this reason, not all problems include sender notifications.

There are two methods of notifying senders:

- [MMS notifications](#)
- [Replacement messages](#)

And three details to consider for logging and notifying administrators:

- [Logging and reporting](#)
- [MMS logging options](#)
- [SNMP](#)

MMS notifications

MMS notifications enable you to customize notifications for many different situations and differently for all the supported MMS message protocols — MM1, MM3, MM4, and MM7.

MMS notification types include:

- Content Filter
- File Block
- Carrier Endpoint Block
- Flood
- Duplicate
- MMS Content Checksum
- Virus Scan

Day of Week, **Window start time** and **Window Duration** define what days and what time of day alert notifications will be sent. This allows you to control what alerts are sent on weekends. It also lets you control when to start sending notifications each day. This can be useful if system maintenance is performed at the same time each night — you might want to start alert notifications after maintenance has completed. Another reason to limit the time alert messages are sent could be to limit message traffic to business hours.

Replacement messages

FortiGate units send replacement messages when messages or content is blocked, quarantined, or otherwise diverted from the receiver. In its place a message is sent to notify the receiver what happened.

With FortiOS Carrier MMS replacement messages, send and receive message types are supported separately and receive their own custom replacement messages. This allows the network to potentially notify both the sender and receiver of the problem.

For example the replacement message **MM1 send-req file block message** is sent to the device that sent one or more files that were banned. The default message that is sent is `This device has sent %%NUM_MSG%% messages containing banned files in the last %%DURATION%% hours. The two variables are replaced by the appropriate values.`

Replacement messages are not as detailed or specific as MMS notifications, but they are also not as complicated to configure. They are also useful when content has been removed from an MMS message that was still delivered.

Logging and reporting

With each virus infection, or file block, a syslog message is generated. The format of this syslog message is similar to:

```
2005-09-22 19:15:47 deviceid=FGT5001ABCDEF1234 logid=0211060ABC type=virus
  subtype=infected level=warning src=10.1.2.3 dst=10.2.3.4 srcintf=port1 dstintf=port2
  service=mm1 status=blocked from="<sending MSISDN>" to="<receiving MSISDN>"
```

```
file="eicar.com.txt" virus="EICAR_TEST_FILE" msg="The file eicar.com.txt is infected
with EICAR_TEST_FILE. ref
http://www.fortinet.com/VirusEncyclopedia/search/encyclopediaSearch.do?method=quickSea
rchDirectly&virusName=EICAR_TEST_FILE"
```

Note that the **from** and **to** fields are samples and not real values.

MMS logging options

You can enable logging in an MMS protection profile to write event log messages when the MMS protection profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS protection profile logging options to write an event log message every time a virus is detected.

To record these log messages you must first configure how the FortiOS Carrier unit stores log messages.

To configure MMS content archiving, go to **Security Profiles > MMS Profile**. Select **Create New** or select the **Edit** icon beside an existing profile. Expand **MMS Bulk AntiSpam Detection > Logging**. Complete the fields as described in the following table and select **OK**. For more a detailed list of options, see Logging.

SNMP

A simple SNMP trap will be generated to inform the operators' alerting system that a virus has been detected. This SNMP trap could contain the sending and receiving MSISDN, however the initial solution would reflect the current behavior, i.e. only the fact that a virus has been detected will be communicated.

MMS content-based Antispam protection

Expand **MMS Scanning** and select **Content Filter** in an MMS protection profile to create content filter black/white lists that block or allow MMS messages based on the content of the message.

Overview

A school computer lab may block age-inappropriate content. A place of business may block unproductive content. A public access internet cafe may block offensive and graphic content. Each installation has its own requirements for what content needs to be blocked, and in what language.

FortiOS Carrier provides the ability to create custom local dictionaries, black lists, and white lists in multiple languages enables you to protect your customers from malicious content around the world.

Configurable dictionary

You can create a dictionary of configurable terms and phrases using the CLI. The text of MMS messages will be searched for these terms and phrases. Add content filter lists that contain content that you want to match in MMS messages. For every match found, a score is added. If enough matches are found to set the total score above the configured threshold, the MMS message is blocked.

You can add words, phrases, wild cards and Perl regular expressions to create content patterns that match content in MMS messages. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.

For each pattern you can select **Block** or **Exempt**.

- Block adds an antispam black list pattern. A match with a block pattern blocks a message depending on the score of the pattern and the content filter threshold.

- Exempt adds an antispam white list pattern. A match with an exempt pattern allows the message to proceed through the FortiOS Carrier unit, even if other content patterns in the same content filter list would block it.

If a pattern contains a single word, the FortiOS Carrier unit searches for the word in MMS messages. If the pattern contains a phrase, the FortiOS Carrier unit searches for all of the words in the phrase. If the pattern contains a phrase in quotation marks, the FortiOS Carrier unit searches for the whole phrase.

You can create patterns with Simplified Chinese, Traditional Chinese, Cyrillic, French, Japanese, Korean, Spanish, Thai, or Western character sets.

Black listing

Black listing is the practice of banning entries on the list. For example if an IP address continuously sends viruses, it may be added to the black list. That means any computers that consult that list will not communicate with that IP address.

Sometimes computers or devices can be added to black lists for a temporary problem, such as a virus that is removed when notified. However, as a rule short of contacting the administrator in person to manually be removed from the black list, users have to wait and they generally will be removed after a period without problem.

White listing

White listing is the practice of adding all critical IP addresses to a list, such as company email and web servers. Then if those servers become infected and start sending spam or viruses, those servers are not blocked. This allows the critical traffic through, even if there might be some malicious traffic as well. Blocking all traffic from your company servers would halt company productivity.

Scores and thresholds

Each content pattern includes a score. When a MMS message is matched with a pattern the score is recorded. If a message matches more than one pattern or matches the same pattern more than once, the score for the message increases. When the total score for a message equals or exceeds the threshold the message is blocked.

The default score for a content filter list entry is 10 and the default threshold is 10. This means that by default a message is blocked by a single match. You can change the scores and threshold so that messages can only be blocked if there are multiple matches. For example, you may only want to block messages that contain the phrase "example" if it appears twice. To do this, add the "example" pattern, set action to block and score to 5. Keep the threshold at 10. If "example" is found twice or more in a message the score adds up 10 (or more) and the message is blocked.

Configuring content-based antispam protection

To apply content-based antispam protection - CLI

```
config webfilter content
  edit <filter_table_number>
    set name <filter_table_name>
    config entries
      edit <phrase or regexp you want to block>
        set action {block | exempt}
        set lang <phrase language>
        set pattern-type {wildcard | regexp}
        set score <phrase score>
        set status {enable | disable}
      end
    end
```

end

Configuring sender notifications

When someone on the MMS network sends an MMS message that is blocked, in most cases you will notify the sender. Typically an administrator is notified in addition to the sender so action can be taken if required. There are two types of sender notifications available in FortiOS Carrier: MMS notifications, and Replacement Messages.

MMS notifications

MMS notifications to senders are configured in **Security Profiles > MMS Profile**, under MMS Notifications.

In this section you can configure up to four different notification recipients for any combination of MM1/3/4/7 protocol MMS messages. Also for MM7 messages the message type can be `submit.REQ` or `deliver.REQ`.

Useful settings include:

- delay in message based on notification type
- limit on notifications per second to prevent a flood
- schedules for notifications
- log in details for MM7 messages.

For more information on MMS notifications, see Notifying message flood senders and receivers and MMS Notifications.

Replacement messages

Replacement messages are features common to both FortiOS and FortiOS Carrier, however FortiOS Carrier has additional messages for the MMS traffic.

While each MMS protocol has its own different replacement messages, the one common to all MMS protocols is the **MMS blocked content replacement message**. This is the message that the receiver of the message sees when their content is blocked.

MMS DLP archiving

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management service. DLP archiving is available for FortiAnalyzer when you add a FortiAnalyzer unit to the FortiOS Carrier configuration. The FortiGuard Analysis and Management server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

You can configure full DLP archiving and summary DLP archiving. Full DLP archiving includes all content, for example, full email DLP archiving includes complete email messages and attachments. Summary DLP archiving includes just the meta data about the content, for example, email message summary records include only the email header.

You can archive MM1, MM3, MM4, and MM7 content.

Configuring MMS DLP archiving

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. For each protocol you can archive just session metadata (**Summary**), or metadata and a copy of the associated file or message (**Full**).

In addition to MMS protection profile DLP archive options you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Protection Profile

FortiOS Carrier only allows one sixteenth of its memory for transferring content archive files. For example, for Carrier-enabled FortiGate units with 128 MB RAM, only 8 MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

To configure MMS DLP archiving - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New** or select the **Edit** icon beside an existing profile.
3. Expand **MMS Bulk AntiSpam Detection > Content Archive**.
4. Complete the fields as described in DLP Archive options.
5. Select **OK**.

Viewing DLP archives

You can view DLP archives from the Carrier-enabled FortiGate unit web-based manager. Archives are historical logs that are stored on a log device that supports archiving, such as a FortiAnalyzer unit.

These logs are accessed from either **Log & Report > DLP Archive** or if you subscribed to the FortiCloud service, you can view log archives from there.

The **DLP Archive** menu is only visible if one of the following is true.

- You have configured the FortiGate unit for remote logging and archiving to a FortiAnalyzer unit.
- You have subscribed to FortiCloud.

The following tabs are available when you are viewing DLP archives for one of these protocols.

- **E-mail** to view POP3, IMAP, SMTP, POP3S, IMAPS, SMTPS, and spam email archives.
- **Web** to view HTTP and HTTPS archives.
- **FTP** to view FTP archives.
- **IM** to view AIM, ICQ, MSN, and Yahoo! archives.
- **MMS** to view MMS archives.
- **VoIP** to view session control (SIP, SIMPLE and SCCP) archives.

If you need to view log archives in Raw format, select **Raw** beside the **Column Settings** icon.

GTP basic concepts

GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based), and the base station unit sends the message to the carrier network and eventually the Internet (wired carrier network).

The network system then either sends the message back to a base station and to the destination mobile unit, or forwards the message to the proper carrier's network where it gets routed to the mobile unit.

PDP Context

The packet data protocol (PDP) context is a connection between a mobile station and the end address that goes through the SGSN and GGSN. It includes identifying information about the mobile customer used by each server or device to properly forward the call data to the next hop in the carrier network, typically using a GTP tunnel between the SGSN and GGSN.

When a mobile customer has an active voice or data connection open, both the SGSN and GGSN have the PDP context information for that customer and session.

When a mobile phone attempts to communicate with an address on an external packet network, either an IP or X.25 address, the mobile station that phone is connected to opens a PDP context through the SGSN and GGSN to the end address. Before any traffic is sent, the PDP context must first be activated.

The information included in the PDP context includes the customer's IP address, the IMSI number of the mobile handset, and the tunnel endpoint ID for both the SGSN and GGSN. The ID is a unique number, much like a session ID on a TCP/IP firewall. All this information ensures a uniquely identifiable connection is made.

Since one mobile device may have multiple connections open at one time, such as data connections to different Internet services and voice connections to different locations, there may be more than one PDP context with the same IP address making the extra identifying information required.

The endpoint that the mobile phone is connecting to only knows about the GGSN — the rest of the GPRS connection is masked by the GGSN.

Along the PDP context path, communication is accomplished in using three different protocols.

- The connection between the Mobile Station and SGSN uses the SM protocol.
- Between SGSN and GGSN GTP is used.
- Between GGSN and the endpoint either IP or X.25 is used.

FortiOS Carrier is concerned with the SGSN to GGSN part of the PDP context — the part that uses GTP.

For more about PDP context, see Tunnel Management Messages.

Creating a PDP context

While FortiOS Carrier is concerned mostly with the SGSN to GGSN part of the PDP Context, knowing the steps involved in creating a PDP context helps understand the role each device, protocol, and message type plays.

Both mobile stations and GGSNs can create PDP contexts.

A Mobile Station creates a PDP context

1. The Mobile Station (MS) sends a `PDP activation request` message to the SGSN including the MS PDP address, and APN.
2. Optionally, security functions may be performed to authenticate the MS.
3. The SGSN determines the GGSN address by using the APN identifier.
4. The SGSN creates a down link GTP tunnel to send IP packets between the GGSN and SGSN.
5. The GGSN creates an entry in its PDP context table to deliver IP packets between the SGSN and the external packet switching network.
6. The GGSN creates an uplink GTP tunnel to route IP-PDU from SGSN to GGSN.
7. The GGSN then sends back to the SGSN the result of the PDP context creation and if necessary the MS PDP address.

8. The SGSN sends an `Activate PDP context accept` message to the MS by returning negotiated the PDP context information and if necessary the MS PDP address.
9. Now traffic can pass from the MS to the external network endpoint.

A GGSN creates a PDP context

1. The network receives an IP packet from an external network.
2. The GGSN checks if the PDP Context has already been created.
3. If not, the GGSN sends a `PDU notification request` to the SGSN in order to initiate a PDP context activation.
4. The GGSN retrieves the IP address of the appropriate SGSN address by interrogating the HLR from the IMSI identifier of the MS.
5. The SGSN sends to the MS a request to activate the indicated PDP context.
6. The PDP context activation procedure follows the one initiated by the MS. See [“A Mobile Station creates a PDP context”](#).
7. When the PDP context is activated, the IP packet can be sent from the GGSN to the MS.

Terminating a PDP context

A PDP context remains open until it is terminated. To terminate the PDP context an MS sends a `Deactivate PDP context` message to the SGSN, which then sends a `Delete PDP Context` message to the GGSN. When the SGSN receives a PDP context deletion acknowledgment from the GGSN, the SGSN confirms to the MS the PDP context deactivation. The PDP can be terminated by the SGSN or GGSN as well with a slight variation of the order of the messages passed.

When the PDP Context is terminated, the tunnel it was using is deleted as well. If this is not completed in a timely manner, it is possible for someone else to start using the tunnel before it is deleted. This hijacking will result in the original customer being over billed for the extra usage. Anti-overbilling helps prevent this. See [Configuring Anti-overbilling in FortiOS Carrier](#).

GPRS security

The GPRS network has some built-in security in the form of GPRS authentication. However this is minimal, and is not sufficient for carrier network security needs. A GTP firewall, such as FortiOS Carrier, is required to secure the Gi, Gn, and Gp interfaces.

GPRS authentication

GPRS authentication is handled by the SGSN to prevent unauthorized GPRS calls from reaching the GSM network beyond the SGSN (the base station system, and mobile station). Authentication is accomplished using some of the customer's information with a random number and uses two algorithms to create ciphers that then allow authentication for that customer.

User identity confidentiality ensures that customer information stays between the mobile station and the SGSN — no identifying information goes past the SGSN. Past that point other numbers are used to identify the customer and their connection on the network.

Periodically the SGSN may request identity information from the mobile station to compare to what is on record, using the IMEI number.

Call confidentiality is achieved through the use of a cipher, similar to the GPRS authentication described earlier. The cipher is applied between the mobile station and the SGSN. Essentially a cipher mask is XORd with each outgoing frame, and the receiving side XORs with its own cipher to result in the original frame and data.

Parts of a GTPv1 network

A sample GTP network consists of the end handset sender, the sender's mobile station, the carrier's network including the SGSN and GGSN, the receiver's mobile station, and the receiver handset.

When a handset moves from one mobile station and SGSN to another, the handset's connection to the Internet using GTP tracks the user's location and information. For example, the handset could move from one cell to another, or between countries.

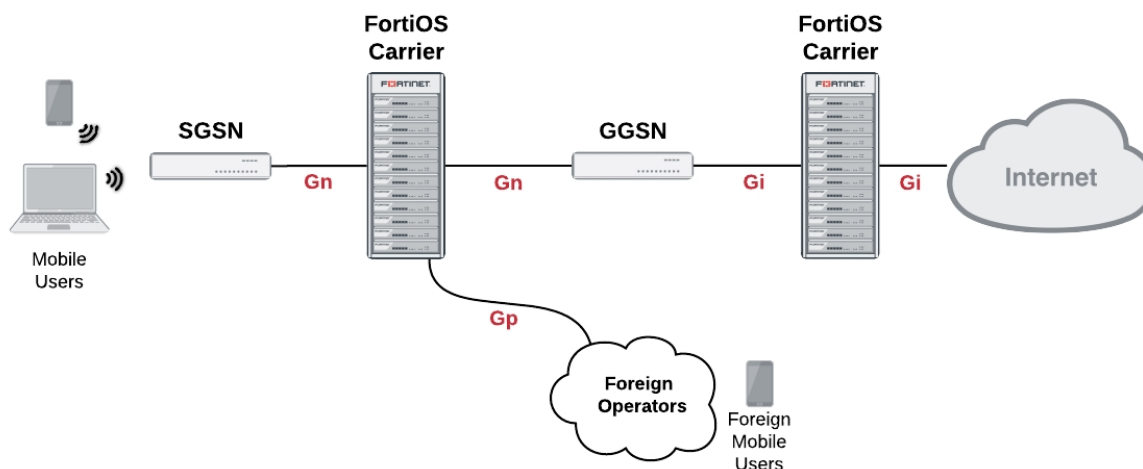

The parts of a GPRS network can be separated into the following groups according to the roles of the devices:

- Radio access to the GPRS network is accomplished by mobile phones and mobile stations (MS).
- Transport the GPRS packets across the GPRS network is accomplished by SGSNs and GGSNs, both local and remote, by delivering packets to the external services.
- Billing and records are handled by CDF, CFR, HLR, and VLR devices.

GPRS networks also rely on access points and PDP contexts as central parts of the communication structure. These are not actual devices, but they are still critical .

These devices, their roles, neighboring devices, the interfaces and protocols they use are outlined in the following table.

Carrier network showing the interfaces used (GTPv1)

Devices on a GTPv1 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
SGSN (local)	MS, SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gb, Gn, Gp, Gz	IP, Frame Relay, GTP, GTP'
SGSN (remote)	SGSN (local)	Gn	GTP
GGSN (local)	SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gi, Gn, Gp, Gz	IP, GTP, GTP'
GGSN (remote)	SGSN (local), WAP gateway, Internet, other external services	Gi, Gp	IP, GTPv1
CDR, CFR	SGSN (local), GGSN (local)	Ga, Gz	GTP'
HLR, VLR	SGSN (local), GGSN (local)	Ga, Gz	GTP'

Radio access

For a mobile phone to access the GPRS core network, it must first connect to a mobile station. This is a cellular tower that is connected to the carrier network.

How the mobile phone connects to the mobile station (MS) is determined by what Radio Access Technologies (RATs) are supported by the MS.

Transport

Transport protocols move data along the carrier network between radio access and the Internet or other carrier networks.

FortiOS Carrier should be present where information enters the Carrier network, to ensure the information entering is correct and not malicious. This means a Carrier-enabled FortiGate unit intercepts the data coming from the SGSN or foreign networks destined for the SSGN or GGSN onto the network, and after the GGSN as the data is leaving the network.

GTP

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over a network via tunneling. This tunneling allows users to move between SGSNs and still maintain connection to the Internet through the GGSN.

GTP has three versions version 0, 1, and 2. GTP1 and GTP2 are supported by FortiOS Carrier. The only GTP commands that are common to all forms of GTP are the echo request/response commands that allow GSNs to verify up to once every 60 seconds that neighboring GSNs are alive.

GTPv0

There have been three versions of GTP to date. The original version of GTP (version 0) has the following differences from version GTPv1.

- the tunnel identification is not random
- there are options for transporting X.25
- the fixed port number 3386 is used for all functions, not just charging
- optionally TCP is allowed as a transport instead of UDP
- not all message types are supported in version 0

GTPv1

On a GPRS network, Packet Data Protocol (PDP) context is a data structure used by both the Serving GPRS Support Node (SGSN) and the Gateway GPRS Support Node (GGSN). The PDP context contains the subscribers information including their access point, IP address, IMSI number, and their tunnel endpoint ID for each of the SGSN and GGSN.

The Serving GPRS Support Node (SGSN) is responsible for the delivery of data packets from and to the mobile stations within its geographical service area. Its tasks include packet routing and transfer, mobility management (attach/detach and location management), logical link management, and authentication and charging functions. The location register of the SGSN stores location information (e.g., current cell, current VLR) and user profiles (e.g., IMSI, address(es) used in the packet data network) of all GPRS users registered with this SGSN.

GTPv1-C

GTPv1-C refers to the control layer of the GPRS Transmission network. This part of the protocol deals with network related traffic.

FortiOS Carrier handles GTPv1-C in GTPv1 by using the Tunnel Endpoint Identifier (TEID), IP address and a Network layer Service Access Point Identifier (NSAPI), sometimes called the application identifier, as an integer value that is part of the PDP context header information used to identify a unique PDP context in a mobile station, and SGSN.

For more information on GTPv1-C, see GTP-C messages.

GTPv1-U

GTPv1-U is defined in 3GPP TS 29.281 and refers to the user layer of the GPRS Tunneling network. This part of the protocol deals with user related traffic, user tunnels, and user administration issues.

A GTPv1-U tunnel is identified by a TEID, an IP address, and a UDP port number. This information uniquely identifies the limb of a GTPv1 PDP context. The IP address and the UDP port number define a UDP/IP path, a connectionless path between two endpoints (i.e. SGSN or GGSN). The TEID identifies the tunnel endpoint in the receiving GTPv1-U protocol entity; it allows for the multiplexing and demultiplexing of GTP tunnels on a UDP/IP path between a given GSN-GSN pair. For more information on GTPv1-U, see GTP-U messages.

The GTP core network consists of one or more SGSNs and GGSNs.

GGSN

The Gateway GPRS Support Node (GGSN) connects the GPRS network on one side via the SGSN to outside networks such as the Internet. These outside networks are called packet data networks (PDNs). The GGSN acts as an edge router between the two different networks — the GGSN forwards incoming packets from the external PDN to the addressed SGSN and the GGSN also forwards outgoing packets to the external PDN. The GGSN also converts the packets from the GPRS packets with SGSN to the external packets, such as IP or X.25.

SGSN

The Serving GPRS Support Node (SGSN) connects the GPRS network to GTPv1 compatible mobile stations, and mobile units (such as UTRAN and ETRAN) on one side and to the gateway node (GGSN), which leads to external networks, on the other side. Each SGSN has a geographical area, and mobile phones in that area connect to the GPRS network through this SGSN. The SGSN also maintains a location register that contains customer's location and user profiles until they connect through a different SGSN at which time the customer information is moved to the new SGSN. This information is used for packet routing and transfer, mobility management also known as location management, logical link management, and authentication and billing functions.

GTPv2

GTPv2, defined in 3GPP TS 29.274, is dramatically different from GTPv1, defined in 3GPP TS 29.060. Where in GTPv1 the tunnel is between the SGSN and the GGSN, in GTPv2 The SGSN is between the MME and the LTE Serving Gateway (S-GW), beyond which is the PDN gateway (P-GW). Even tunnel management messages have changed significantly.

Network diagram for GTPv2

Device roles on a GTPv2 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	--
GTPv1 Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay

Device role	Neighboring Devices	Interfaces used	Protocols used
GTPv2 Mobile Stations (MS)	Mobile Users, MME	???	IP, Frame Relay
SGSN (local)	GTPv1 MS, SGSN, S-GW	???	IP, Frame Relay, GTPv1, GTP'
S-GW	SGSN, MME, P-GW	???	IP, GTPv2, GTP'
P-GW	S-GW, Internet, other external services	???	IP, GTPv2

GTPv2-C

GTPv2-C is the control layer messaging for GTPv2. It is used by LTE mobile stations, SGSN units for backwards compatibility, and SGWs that are the gateway to other networks. The messaging is very different from GTPv1. GTPv2-C is required to communicate with the Mobility Management Entity (MME) to create, change and delete EPS bearers when handover events happen, and to create Forwarding tunnels. The protocol is also used to communicate with the Serving Gateway (SGW) which has the S-GW and PDN-GW interfaces, and the Serving GPRS Support Node (SGSN).

MME

MME essentially fills the role of the SGSN in a GTPv1 network — it is how the mobile stations gain access to the Carrier network. GTPv2 supports different mobile stations than GTPv1, so MME handles the GTPv2 MSes and SGSN handles the GTPv1 MSes

Billing and records

A major part of the GPRS network is devoted to billing. Customer billing requires enough information to identify the customer, and then billing specific information such as connection locations and times, as well as amount of data transferred. A modified form of GTP called GTP' is used for billing. The home location records and visitor location records store information about customers that is critical to billing.

GTP' (GTP prime)

GTP is used to handle tunnels of user traffic between SGSNs and GGSNs. However for billing purposes, other devices that are not supported by GTP are required. GTP' (GTP prime) is a modified form of GTP and is used to communicate with these devices such as the Charging Data Function (CDF) that communicates billing information to the Charging Gateway Function (CGF). In most cases, GTP' transports user records from many individual network elements, such as the GGSNs, to a centralism computer which then delivers the charging data more conveniently to the network operator's billing center, often through the CGF. The core network sends charging information to the CGF, typically including PDP context activation times and the quantity of data which the end user has transferred.

GTP' is used by the Ga and Gz interfaces to transfer billing information. GTP' uses registered UDP/TCP port 3386. GTP' defines a different header, additional messages, field values, as well as a synchronization protocol to avoid losing or duplicating CDRs on CGF or SGSN/GGSN failure. Transferred CDRs are encoded in ASN.1.

HLR

The Home Location Register (HLR) is a central database that contains details of each mobile phone subscriber that is authorized to use the GSM core network. There can be several logical, and physical, HLRs per public land mobile network (PLMN), though one international mobile subscriber identity (IMSI)/MSISDN pair can be associated with only one logical HLR (which can span several physical nodes) at a time. The HLRs store details of every SIM card issued by the mobile phone operator. Each SIM has a unique identifier called an IMSI which is the primary key to each HLR record.

VLR

The Visitor Location Register (VLR) is a database which stores information about all the mobile devices that are currently under the jurisdiction of the Mobile Switching Center which it serves. Of all the information the VLR stores about each Mobile Station, the most important is the current Location Area Identity (LAI). This information is vital in the call setup process.

Whenever an MSC detects a new MS in its network, in addition to creating a new record in the VLR, it also updates the HLR of the mobile subscriber, informing it of the new location of that MS.

For more information on GTP', see GTP-U and Charging Management Messages.

GPRS network common interfaces

There are interfaces for each connection on the GPRS network. An interface is an established standard form of communication between two devices. Consider a TCP/IP network. In addition to the transport protocol (TCP) there are other protocols on that network that describe how devices can expect communications to be organized, just like GPRS interfaces.

Interfaces between devices on the network

There are a series of interfaces that define how different devices on the carrier network communicate with each other. These interfaces are called Ga to Gz, and each one defines how a specific pair of devices will communicate. For example Gb is the interface between the base station and the SGSN, and Gn is one possible interface between the SGSN and GGSN.

The SGSN and GGSN keep track of the CDR information and forward it to the Charging Data Function (CDF) using the Gr interface between the SGSN and home location register (HLR), Gs interface between the SGSN and MSC (VLR), Gx interface between the GGSN and the Charging Rules Function (CRF), Gy between the GGSN and online charging system (OCS), and finally Gz which is the off-line (CDR-based) charging interface between the GSN and the CG that uses GTP'.

Each of these interfaces on the GPRS network has a name in the format of G_x where x is a letter of the alphabet that determines what part of the network the interface is used in. It is common for network diagrams of GPRS networks to include the interface name on connections between devices.

The Carrier-enabled FortiGate unit only provides protection on the Gn, Gp, and Gi interfaces.

GPRS network interfaces, their roles, and billing

Name	Device connections that use this interface	Traffic Protocol used	Its role or how it affects billing
Ga	CDR and GSN (SGSNs and GGSNs)	GTP ^a - GTP modified to include CDR role	CDR have the accounting records, that are compiled in the GSN and then sent to the Charging Gateway (CG)
Gb	MS and SGSN	Frame Relay or IP	When an IP address moves to a new MS, the old MS may continue to use and bill that IP address.
Gi	GGSN and public data networks (PDNs)	IP based	This is the connection to the Internet. If the GTP tunnel is deleted without notifying the Gi interface, the connection may remain open incurring additional charges. FortiOS Carrier adds this interface to a firewall. See Anti-overbilling with FortiOS Carrier.
Gn	SGSN and external SGSNs and internal GGSNs	GTP	When the GTP tunnel is deleted, need to inform other interfaces immediately to prevent misuse of connections remaining open. FortiOS Carrier adds this interface to a firewall.
Gp	Internal SGSN and external GGSNs	GTP	
Gz	GSN (SGSN and GGSN) and the charging gateway (CG)	GTP ^a	Used for the offline charging interface. Ga is used for online charging.

Corporate customers may have a direct connection to the Gi interface for higher security. The Gi interface is normally an IP network, though a tunnelling protocol such as GRE or IPsec may be used instead.

GTP Configuration

The GTP (GPRS Tunneling Protocol) is one of the major mobile core protocols used since to transfer data in the core mobile network. Mobility and data are exploding and this trend will continue with VoLTE, 5G, and the Internet of Things (IoT). The role of GTP in mobile networks will continue to remain critical.

With the mobile network ever growing importance as the communication channel for data rich application on mobile devices, connected intelligent devices and the IoT, comes the growing potential for attacks on the mobile infrastructure.

Introduction to GTP

GTP as a Potential Attack Vector

GTP's role in transferring data in the core mobile infrastructure makes it a potential ideal attack vector. To understand the security features for GTP we need to understand the risks that might compromise this protocol.

The business impact might vary in-between the different attacks from Denial of Service (DoS) attacks that hinders the capability of performing a legitimate operation due to resource starvation (for example - not being able to charge the customer for GPRS traffic use due to denial of service attack on the Charging GW) to remote compromise attacks that allows the hacker to have remote control of a critical device (for example – take control over a GGSN).

GTP-based attacks may have a wide range of business impact, based on the attacked devices' vulnerability, ranging from service unavailability, compromise customer information, and gaining control over infrastructure elements, just to give a few examples.

Listed below are the main categories of GTP-based attacks:

- **Protocol anomaly attacks** are packets and packets formats that should not be expected on the GTP protocol. These can include malformed packets, reserved packets' fields and types, etc.
- **Infrastructure attacks** are attempts to connect to restricted core elements, such as the GGSN, SGSN, PGW, etc.
- **Overbilling attacks** results in customers charged for traffic they did not use or the opposite of not paying for the used traffic.

Protecting Against GTP-Based Attacks: The Carrier Grade GTP Firewall

With the evolution of the mobile network so has GTP evolved. The awareness to the potential of GTP-based attacks has led mobile core vendors to harden their software to better deal with a potential attack. Alongside this evolution, network security vendors, such as Fortinet, has led the way in providing specific GTP aware firewalls to secure and protect the different versions of the GTP protocol from potential attacks.

A GTP firewall should be placed where GTP traffic and session originate and terminate, as shown in the below diagram, and has to inspect both the GTP-C (Control Plane) and GTP-U (Data Plane) packets that, together, constitute the GPRS Tunneling Protocol.

The GTP firewall in both cases is placed in line between the SGSN / SGW and the GGSN / PGW which are the initiator and terminator of the GTP traffic. One of the main roles of GTP firewall is also to be able to support the roaming between different versions of GTP without interrupting the service.

The GTP firewall must be carrier grade in its ability to scale and provide high availability without impact its ability to provide effective protection.

FortiGate with FortiCarrier – The Leading GTP Firewall

FortiGate is Fortinet's physical security platform, built specifically for high performance and scalability with the utilization of specialized FortiASIC technology. Fortinet Content Processors (CP) and Network Processors (NP) enable, offloading CPU intensive tasks and allowing the FortiGate to provide carrier grade performance and scalability. Utilizing the power of the FortiGate platform, FortiOS, Fortinet's security Operating System, provides threat intelligence and advanced functionalities to provide effective security, ranging from Carrier Grade NAT (CGNAT), firewalling, IPSec, etc.

FortiCarrier is the part of FortiOS which was specifically designed to provide security for specific carriers and mobile operators' protocols and requirements, such as awareness and security for GTP. The wide range of FortiGate platforms with FortiOS and FortiCarrier enables mobile operators to cost effectively secure their mobile network against GTP-based attacks, while ensuring unparalleled performance, availability and security effectiveness.

GTP Profile

You can configure multiple GTP profiles within the GTP menu. GTP profiles concern GTP activity flowing through the unit. These GTP profiles are then applied to a security policy.

GTP profile configuration settings

The following are GTP profile configuration settings in **Security Profiles > GTP Profiles**.

GTP Profile	
Lists each GTP profile that you have created. On this page, you can edit, delete or create a new GTP profile.	
Create New	Creates a new GTP profile. When you select Create New , you are automatically redirected to the New page.
Edit	Modifies settings within a GTP profile in the list. When you select Edit , you are automatically redirected to Edit page.
Delete	Removes a GTP profile from the list.
	To remove multiple GTP profiles from within the list, on the GTP Profile page, in each of the rows of the profiles you want removed, select the check box and then select Delete .
	To remove all GTP profiles from within the list, on the GTP Profile page, select the check box in the check box column and then select Delete .
Name	The name of the GTP profile.

Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** .

To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object.

To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:

Ref.

- **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at.
- **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page.
- **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

New GTP Profile

Provides settings for configuring a GTP profile.

Name	Enter a name for the GTP profile.
General Settings	Configure general options for the GTP profile.
Message Type Filtering	Configure filtering for messages.
APN Filtering	Configure filtering options for APN.
Basic Filtering	Configure filtering options for IMSI.
Advanced Filtering	Configure advanced filtering options.
IE removal policy	Configure IE removal policy options.
Encapsulated IP Traffic Filtering	Configure filtering options for encapsulated IP traffic.
Encapsulated Non-IP End User Address Filtering	Configure filtering options for encapsulated non-IP end user addresses.
Protocol Anomaly	Configure protocol anomaly options.

Anti-Overbilling	Configure anti-overbilling options.
-------------------------	-------------------------------------

Log	Configure log options.
------------	------------------------

General settings options

The following are mostly house keeping options that appear in the General Settings area of the GTP configuration page.

General Settings section of the New GTP Profile

GTP-in-GTP	<p>Select Allow to enable GTP packets to be allowed to contain GTP packets, or a GTP tunnel inside another GTP tunnel.</p> <p>To block all GTP-in-GTP packets, select Deny.</p>
Minimum Message Length	<p>Enter the shortest possible message length in bytes. Normally this is controlled by the protocol, and will vary for different message types. If a packet is smaller than this limit, it is discarded as it is likely malformed and a potential security risk.</p> <p>The default minimum message length is 0 bytes.</p>
Maximum Message Length	<p>Enter the maximum allowed length of a GTP packet in bytes.</p> <p>A GTP packet contains three headers and corresponding parts GTP, UDP, and IP. If a packet is larger than the maximum transmission unit (MTU) size, it is fragmented to be delivered in multiple packets. This is inefficient, resource intensive, and may cause problems with some applications.</p> <p>By default the maximum message length is 1452 bytes.</p>
Tunnel Limit	<p>Enter the maximum number of tunnels allowed open at one time. For additional GTP tunnels to be opened, existing tunnels must first be closed.</p> <p>This feature can help prevent a form of denial of service attack on your network. This attack involves opening more tunnels than the network can handle and consuming all the network resources doing so. By limiting the number of tunnels at any one time, this form of attack will be avoided.</p> <p>The tunnel limiting applies to the Handover Group, and Authorized SGSNs and GGSNs.</p>

General Settings section of the New GTP Profile

Tunnel Timeout	<p>Enter the maximum number of seconds that a GTP tunnel is allowed to remain active. After the timeout the unit deletes GTP tunnels that have stopped processing data. A GTP tunnel may hang for various reasons. For example, during the GTP tunnel tear-down stage, the "delete pdap context response" message may get lost. By setting a timeout value, you can configure the FortiOS Carrier firewall to remove the hanging tunnels.</p> <p>The default is 86400 seconds, or 24 hours.</p>
Control plane message rate limit	<p>Enter the number of packets per second to limit the traffic rate to protect the GSNs from possible Denial of Service (DoS) attacks. The default limit of 0 does not limit the message rate.</p> <p>GTP DoS attacks can include:</p> <ul style="list-style-type: none"> • Border gateway bandwidth saturation: A malicious operator can connect to your GRX and generate high traffic towards your Border Gateway to consume all the bandwidth. • GTP flood: A GSN can be flooded by illegitimate traffic
Handover Group	<p>Select the allowed list of IP addresses allowed to take over a GTP session when the mobile device moves locations.</p> <p>Handover is a fundamental feature of GPRS/UMTS, which enables subscribers to seamlessly move from one area of coverage to another with no interruption of active sessions. Session hijacking can come from the SGSN or the GGSN, where a fraudulent GSN can intercept another GSN and redirect traffic to it. This can be exploited to hijack GTP tunnels or cause a denial of service.</p> <p>When the handover group is defined it acts like a white list with an implicit default deny at the end — the GTP address must be in the group or the GTP message will be blocked. This stops handover requests from untrusted GSNs.</p>
Authorized SGSNs	<p>Use Authorized SGSNs to only allow authorized SGSNs to send packets through the unit and to block unauthorized SGSNs. Go to Firewall Objects > Address > Addresses and add the IP addresses of the authorized SGSNs to a firewall address or address group. Then set Authorized SGSNs to this firewall address or address group.</p> <p>You can use Authorized SGSNs to allow packets from SGSNs that have a roaming agreement with your organization.</p>

General Settings section of the New GTP Profile

Authorized GGSNs

Use **Authorized GGSNs** to only allow authorized GGSNs to send packets through the unit and to block unauthorized GGSNs. Go to **Firewall Objects > Address > Addresses** and add the IP addresses of the authorized GGSNs to a firewall address or address group. Then set **Authorized GGSNs** to this firewall address or address group.

You can use Authorized GGSNs to allow packets from SGSNs that have a roaming agreement with your organization.

Message type filtering options

On the **New GTP Profile** page, you can select to allow or deny the different types of GTP messages, which is referred to as message type filtering. You must expand the Message Type Filtering section to access the settings.

The messages types include Path Management, Tunnel Management, Location Management, Mobility Management, MBMS, and GTP-U and Charging Management messages.

For enhanced security, Fortinet best practices dictate that you set Unknown Message Action to deny. This will block all unknown GTP message types, some of which may be malicious.

To configure message type filter options, expand **Message Type Filtering** in the GTP profile.

APN filtering options

An Access Point Name (APN) is an Information Element (IE) included in the header of a GTP packet. It provides information on how to reach a network.

An APN has the following format:

```
<network_id>[.mnc<mnc_int>.mcc<mcc_int>.gprs]
```

Where:

- **<network_id>** is a network identifier or name that identifies the name of a network, for example, `example.com` or `internet`.
- **[.mnc<mnc_int>.mcc<mcc_int>.gprs]** is the optional operator identifier that uniquely identifies the operator's PLMN, for example `mnc123.mcc456.gprs`.

Combining these two examples results in a complete APN of `internet.mnc123.mcc456.gprs`.

By default, the unit permits all APNs. However, you can configure APN filtering to restrict roaming subscribers' access to external networks.

APN filtering applies only to the GTP **create pdp request** messages. The unit inspects GTP packets for both APN and selected modes. If both parameters match and APN filter entry, the unit applies the filter to the traffic.

Additionally, the unit can filter GTP packets based on the combination of an IMSI prefix and an APN.

You cannot add an APN when creating a new profile.

APN Filtering	
Enable APN Filter	Select to enable APN filtering.
Default APN Action	Select the default action for APN filtering. If you select Allow , all sessions are allowed except those blocked by individual APN filters. If you select Deny , all sessions are blocked except those allowed by individual APN filters.
Value	The APN to be filtered.
Mode	The type of mode chosen that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription:
Action	The type of action that will be taken.
Edit	Modifies the settings within the filter. When you select Edit , the Edit window appears, which allows you to modify the settings of the APN.
Delete	Removes the APN from the list within the table, in the APN Filtering section.
Add APN	Adds a new APN filter to the list. When you select Add APN , the New window appears, which allows you to configure the APN settings.
New APN page	
Value	Enter an APN to be filtered. You can include wild cards to match multiple APNs. For example, the value internet* would match all APNs that begin with internet .
Mode	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
Action	Select Allow or Deny .

Basic filtering options

The International Mobile Station Identity (IMSI) is used by a GPRS Support Node (GSN) to identify a mobile station. Three elements make up every IMSI:

- the mobile country code (MCC)
- the mobile network code (MNC)
- the mobile subscriber identification number (MSIN).

The subscriber's home network—the public land mobile network (PLMN)—is identified by the IMSI prefix, formed by combining the MCC and MNC.

By default, the unit allows all IMSIs. You can add IMSI prefixes to deny GTP traffic coming from non-roaming partners. Any GTP packets with IMSI prefixes not matching the prefixes you set will be dropped. GTP **Create pdp** request messages are filtered and only IMSI prefixes matching the ones you set are permitted. Each GTP profile can have up to 1000 IMSI prefixes set.

An IMSI prefix and an APN can be used together to filter GTP packets if you set an IMSI filter entry with a non-empty APN.

You cannot add an IMSI when creating a new profile. You must add it after the profile has been created and you are editing the profile.

IMSI Filtering section of the New GTP Profile

Enable IMSI Filter	Select to enable IMSI filtering.
Default IMSI Action	Select the default action for IMSI filtering. If you select Allow , all sessions are allowed except those blocked by individual IMSI filters. If you select Deny , all sessions are blocked except those allowed by individual IMSI filters.
APN	The APN that is part of the IMSI that will be filtered.
MCC-MNC	The MCC-MNC part of the IMSI that will be filtered.
Mode	The type of mode that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Action	The type of action that will be taken.
Edit	Modifies settings to an IMSI filter. When you select Edit , the Edit window appears, which allows you to modify the IMSI filter's settings.
Delete	Removes an IMSI filter from within the table, in the IMSI Filtering section.
Add IMSI	Adds a new IMSI filter to the list. When you select Add IMSI , the New window appears, which allows you to configure IMSI filter settings.
New IMSI page	

APN	Enter the APN part of the IMSI to be filtered.
MCC-MNC	Enter the MCC-MCC part of the IMSI to be filtered.
Mode	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
Action	Select Allow or Deny .

Advanced filtering options

The FortiOS Carrier firewall supports advanced filtering against the attributes RAT, RAI, ULI, APN restriction, and IMEI-SV in GTP to block specific harmful GPRS traffic and GPRS roaming traffic. The following table shows some of the GTP context requests and responses that the firewall supports.

Attributes supported by FortiCarrier firewalls

	GTP Create PDP Context Request	GTP Create PDP Context Response	GTP Update PDP Context Request	GTP Update PDP Context Response
APN	yes	yes	-	
APN Restriction	yes	-	-	yes
IMEI-SV	yes	-	-	-
IMSI	yes	-	yes	-
RAI	yes	-	yes	-
RAT	yes	-	yes	-
ULI	yes	-	yes	-

When editing a GTP profile, select **Advanced Filtering > Create New** to create and add a rule. When the rule matches traffic it will either allow or deny that traffic as selected in the rule.

Advanced Filtering	
Enable	Select to enable advanced filtering.
Default Action	Select the default action for advanced filtering. If you select Allow , all sessions are allowed except those blocked by individual advanced filters. If you select Deny , all sessions are blocked except those allowed by individual advanced filters.
Messages	The messages, for example, Create PDP Context Request.
APN Restriction	The APN restriction.
RAT Type	The RAT types associated with that filter.
ULI	The ULI pattern.
RAI	The RAI pattern.
IMEI	The IMEI pattern.
Action	The action that will be taken.
Edit	Modifies the filter's settings. When you select Edit , the Edit window appears, which allows you to modify the filter's settings.
Delete	Removes a filter from the list.
Add	Adds a filter to the list. When you select Add , the New window appears, which allows you to configure settings for messages, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI patterns as well as the type of action.
New Filtering page	
Messages	The PDP content messages this profile will match.
Create PDP Context Request	Select to allow create PDP context requests.
Create PDP Context Response	Select to allow create PDP context responses.
Update PDP Context Request	Select to allow update PDP context requests.

Update PDP Context Response	Select to allow update PDP context responses.
APN	Enter the APN.
APN Mode	<p>Select an APN mode as one or more of</p> <ul style="list-style-type: none"> • Mobile Station provided • Network provided • Subscription provided <p>This field is only available when an APN has been entered.</p>
Mobile Station provided	MS-provided PAN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
Subscription verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
APN Restriction	<p>Select the type of restriction that you want. You can choose all of the types, or one of the types. You cannot choose multiple types. Types include:</p> <ul style="list-style-type: none"> • all • Public-1 • Public-2 • Private-1 • Private-2
IMSI	Enter the IMSI.
MSISDN	Enter the MSISDN.
RAT Type	<p>Optionally select the RAT type as any combination of the following:</p> <ul style="list-style-type: none"> • Any • UTRAN • GERAN • Wifi • GAN • HSPA <p>Some RAT types are GTPv1 specific.</p>

ULI pattern	Enter the ULI pattern.
RAI pattern	Enter the RAI pattern.
IMEI pattern	Enter the IMEI pattern.
Action	Select either Allow or Deny .

Adding an advanced filtering rule

When adding a rule, use the following formats:

- Prefix, for example, range 31* for MCC matches MCC from 310 to 319.
- Range, for example, range 310-319 for MCC matches MCC from 310 to 319.
- Mobile Country Code (MCC) consists of three digits. The MCC identifies the country of domicile of the mobile subscriber.
- Mobile Network Code (MNC) consists of two or three digits for GSM/UMTS applications. The MNC identifies the home PLMN of the mobile subscriber. The length of the MNC (two or three digits) depends on the value of the MCC. Best practices dictate not to mix two and three digit MNC codes within a single MCC area.
- Location Area Code (LAC) is a fixed length code (of 2 octets) identifying a location area within a PLMN. This part of the location area identification can be coded using a full hexadecimal representation except for the following reserved hexadecimal values: 0000 and FFFE. These reserved values are used in some special cases when no valid LAI exists in the MS (see 3GPP TS 24.008, 3GPP TS 31.102 and 3GPP TS 51.011).
- Routing Area Code (RAC) of a fixed length code (of 1 octet) identifies a routing area within a location.
- CI or SAC of a fixed length of 2 octets can be coded using a full hexadecimal expression.
- Type Allocation Code (TAC) has a length of 8 digits.
- Serial Number (SNR) is an individual serial number identifying each equipment within each TAC. SNR has a length of 6 digits.
- Software Version Number (SVN) identifies the software version number of the mobile equipment. SVN has a length of 2 digits.

You cannot add an advanced filtering rule when creating a new profile. You must add it after the profile has been created and you are editing the profile.

Information Element (IE) removal policy options

In some roaming scenarios, the unit is installed on the border of the PLMN and the GRX. In this configuration, the unit supports information element (IE) removal policies to remove any combination of R6 IEs (RAT, RAI, ULI, IMEI-SV and APN restrictions) from the types of messages described in “[Advanced filtering options](#)”, prior to forwarding the messages to the HGGSN (proxy mode).

IE removal policy	
Enable	Select to enable this option.

SGSN address of message IE	The firewall address or address group that contains the SGSN addresses.
IEs to be removed	The IE types that will be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.
Add	Adds an IE removal policy. When you select Add , the New window appears, which allows you to configure the IE policy.
Edit	Modifies settings from within the IE removal policy. When you select Edit , the Edit window appears, which allows you to modify the settings within the policy.
Delete	Removes the IE removal policy from the list.
New IE policy page	
SGSN address	Select a firewall address or address group that contains SGSN addresses.
IEs to be removed	Select one or more IE types to be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.

Encapsulated IP traffic filtering options

You can use encapsulated IP traffic filtering to filter GTP sessions based on information contained in the data stream. to control data flows within your infrastructure. You can configure IP filtering rules to filter encapsulated IP traffic from mobile stations by identifying the source and destination policies. For more information, see When to use encapsulated IP traffic filtering.

Expand **Encapsulated IP Traffic Filtering** in the GTP profile to reveal the options.

Encapsulated IP Traffic Filtering	
Enable IP Filter	Select to enable encapsulated IP traffic filtering options.
Default IP Action	Select the default action for encapsulated IP traffic filtering. If you select Allow , all sessions are allowed except those blocked by individual encapsulated IP traffic filters. If you select Deny , all sessions are blocked except those allowed by individual encapsulated IP traffic filters.
Source	Select a source IP address from the configured firewall IP address or address group lists. Any encapsulated traffic originating from this IP address will be a match if the destination also matches.
Destination	Select a destination IP address from the configured firewall IP address or address group lists. Any encapsulated traffic being sent to this IP address will be a match if the destination also matches.

Action	The type of action that will be taken. Select to Allow or Deny encapsulated traffic between this source and Destination.
Edit	Modifies the source, destination or action settings.
Add IP Policy	Adds a new encapsulated IP traffic filter. When you select Add IP Policy , the New window appears which allows you to configure IP policy settings.
New (window)	
Source	Select the source firewall address or address group.
Destination	Select the destination firewall address or address group.
Action	Select Allow or Deny .

Encapsulated non-IP end user traffic filtering options

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications list only PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

Encapsulated Non-IP End User Address Filtering	
Enable Non-IP Filter	Select to enable encapsulated non-IP traffic filtering.
Default Non-IP Action	Select the default action for encapsulated non-IP traffic filtering. If you select Allow , all sessions are allowed except those blocked by individual encapsulated non-IP traffic filters. If you select Deny , all sessions are blocked except those allowed by individual encapsulated non-IP traffic filters.
Type	The type chosen, AESTI or IETF .
Start Protocol	The beginning protocol port number range.
End Protocol	The end of the protocol port number range.
Action	The type of action that will be taken.

Edit	Modify a non-IP filter's settings in the list. When you select Edit , the Edit window appears, which allows you to modify the Non-IP policy settings.
Delete	Remove a non-IP policy from the list.
Add Non-IP Policy	Add a new encapsulated non-IP traffic filter. When you select Add Non-IP Policy , you are automatically redirected to the New page.
New (window)	
Type	Select AESTI or IETF .
Start Protocol	Select a start and end protocol from the list of protocols in RFC 1700. Allowed range includes 0 to 255 (0x00 to 0xff). Some common protocols include: <ul style="list-style-type: none"> • 33 (0x0021) Internet Protocol • 35 (0x0023) OSI Network Layer • 63 (0x003f) NETBIOS Framing • 65 (0x0041) Cisco Systems • 79 (0x004f) IP6 Header Compression • 83 (0x0053) Encryption
End Protocol	
Action	Select Allow or Deny .

Protocol Anomaly prevention options

Use protocol anomaly detection options to detect or deny protocol anomalies according to GTP standards and tunnel state. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of the protocol specifications. Packets cannot pass through if they fail the sanity check.

Protocol Anomaly	
Invalid Reserved Field	GTP version 0 (GSM 09.60) headers specify a number of fields that are marked as "Spare" and contain all ones (1). GTP packets that have different values in these fields are flagged as anomalies. GTP version 1 (GSM 29.060) makes better use of the header space and only has one, 1-bit, reserved field. In the first octet of the GTP version1 header, bit 4 is set to zero.
Reserved IE	Both versions of GTP allow up to 255 different Information Elements (IE). However, a number of Information Elements values are undefined or reserved. Packets with reserved or undefined values will be filtered.
Miss Mandatory IE	GTP packets with missing mandatory Information Elements (IE) will not be passed to the GGSN.

Out of State Message	<p>The GTP protocol requires a certain level of state to be kept by both the GGSN and SGSN. Some message types can only be sent when in a specific GTP state. Packets that do not make sense in the current state are filtered or rejected.</p> <p>Both versions of GTP allow up to 255 different message types. However, a number of message type values are undefined or reserved.</p> <p>Best practices dictate that packets with reserved or undefined values will be filtered.</p>
Out of State IE	GTP Packets with out of order Information Elements are discarded.
Spoofed Source Address	<p>The End User Address Information Element in the PDP Context Create & Response messages contain the address that the mobile station (MS) will use on the remote network. If the MS does not have an address, the SGSN will set the End User Address field to zero when sending the initial PDP Context Create message. The PDP Context Response packet from the GGSN will then contain an address to be assigned to the MS. In environments where static addresses are allowed, the MS will relay its address to the SGSN, which will include the address in the PDP Context Create Message. As the MS address is negotiated within the PDP Context creation handshake, any packets originating from the MS that contain a different source address are detected and dropped.</p>

Anti-Overbilling options

You can configure the FortiOS Carrier firewall to prevent over billing subscribers for traffic over the. To enable anti-overbilling, you must configure both the Gn/Gp firewall and the Gi firewall.

Expand **Anti-Overbilling** in the GTP profile to reveal these settings.

Anti-Overbilling	
Gi Firewall IP Address	The IP address of the unit's interface configured as a Gi gateway.
Port	The SG security port number. The default port number is port 21123. Change this number if your system uses a different SG port.
Interface	Select the unit interface configured as a Gi gateway.
Security Context ID	Enter the security context ID. This ID must match the ID entered on the server Gi firewall. The default security context ID is 696.

Log options

All the GTP logs are treated as a subtype of the event logs. To enable GTP logging, you must:

- configure the GTP log settings in a GTP profile

Log	
Log Frequency	<p>Enter the number of messages to drop between logged messages.</p> <p>An overflow of log messages can sometimes occur when logging rate-limited GTP packets exceed their defined threshold. To conserve resources on the syslog server and the Carrier-enabled FortiGate unit, you can specify that some log messages are dropped. For example, if you want only every twentieth message to be logged, set a logging frequency of 20. This way, 20 messages are skipped and the next logged.</p> <p>Acceptable frequency values range from 0 to 2147483674. When set to '0', no messages are skipped.</p>
Forwarded Log	Select to log forwarded GTP packets.
Denied Log	Select to log GTP packets denied or blocked by this GTP profile.
Rate Limited Log	Select to log rate-limited GTP packets.
State Invalid Log	Select to log GTP packets that have failed stateful inspection.
Tunnel Limit Log	Select to log packets dropped because the maximum limit of GTP tunnels for the destination GSN is reached.
Extension Log	<p>Select to log extended information about GTP packets. When enabled, this additional information will be included in log entries:</p> <ul style="list-style-type: none"> • IMSI • MSISDN • APN • Selection Mode • SGSN address for signaling • SGSN address for user data • GGSN address for signaling • GGSN address for user data

Traffic count Log

Select to log the total number of control and user data messages received from and forwarded to the GGSNs and SGSNs that the unit protects.

The unit can report the total number of user data and control messages received from and forwarded to the GGSNs and SGSNs it protects. Alternately, the total size of the user data and control messages can be reported in bytes. The unit differentiates between traffic carried by each GTP tunnel, and also between GTP-User and GTP-Control messages.

The number of messages or the number of bytes of data received from and forwarded to the SGSN or GGSN are totaled and logged if a tunnel is deleted.

When a tunnel is deleted, the log entry contains:

- Timestamp
- Interface name (if applicable)
- SGSN IP address
- GGSN IP address
- TID
- Tunnel duration time in seconds
- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

Specifying logging types

You can configure the unit to log GTP packets based on their status with GTP traffic logging.

The status of a GTP packet can be any of the following 5 states:

- **Forwarded** - a packet that the unit transmits because the GTP policy allows it
- **Prohibited** - a packet that the unit drops because the GTP policy denies it
- **Rate-limited** - a packet that the unit drops because it exceeds the maximum rate limit of the destination GSN
- **State-invalid** - a packet that the unit drops because it failed stateful inspection
- **Tunnel-limited** - a packet that the unit drops because the maximum limit of GTP tunnels for the destination GSN is reached.

The following information is contained in each log entry:

- Timestamp
- Source IP address
- Destination IP address
- Tunnel Identifier (TID) or Tunnel Endpoint Identifier (TEID)
- Message type
- Packet status: forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
- Virtual domain ID or name
- Reason to be denied if applicable.

GTP performance

There are independent Receive and Transmit queues for `gtp-u` process. These queues are and their associated resources are initialized when the `ftp-enhance-mode` is enabled.

CLI changes under system npu

gtp-enhance-mode

```
config system npu
  set gtp-enhance-mode {enable|disable}
end
```

This configuration requires a reboot of the device to initialize the changes.

gtp-enhance-cpu-range

This is used to set the CPUs which can process the GTP-U packet inspection.

```
config system npu
  set gtp-enhance-cpu-range {0|1|2}
end
```

Option	Description
0	Inspect GTPU packets by all CPUs
1	Inspect GTPU packets by Master CPUs
2	Inspect GTPU packets by Slave CPUs

Diagnose commands

```
diagnose npu np6 hbq-stats {all|np xx}
```

Used to see the GTP-U packet counter by all NP or the corresponding np.

```
diagnose npu np6 hbq-stats-clear all /np xx
```

Used to clear the GTP-U packet counter by all NP or the corresponding np.

Verifying the enhance-mode is disabled

Before execute the test or enable/disable the gtp enhance, first check the `gtp-enhance-mode` status as in the example below:

```
config system npu
  get
  gtp-enhance-mode: disable
  gtp-enhance-cpu-range: 0
end
```

If the `gtp-enhance-mode` is `disable`, use the command `diagnose npu np6 hbq-stats all`.

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
Total :0
```

If the `gtp-enhance-mode` is enable, use the command `diagnose npu np6 hbq-stats all`

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
cpu_ 1:0
cpu_ 2:0
cpu_ 3:0
cpu_ 4:0
cpu_ 5:0
cpu_ 6:0
cpu_ 7:0
cpu_ 8:0
cpu_ 9:0
cpu_10:0
cpu_11:0
cpu_12:0
cpu_13:0
cpu_14:0
cpu_15:0
cpu_16:0
cpu_17:0
cpu_18:0
cpu_19:0
cpu_20:0
cpu_21:0
cpu_22:0
cpu_23:0
cpu_24:0
cpu_25:0
cpu_26:0
cpu_27:0
cpu_28:0
cpu_29:0
cpu_30:0
cpu_31:0
cpu_32:0
cpu_33:0
cpu_34:0
cpu_35:0
cpu_36:0
cpu_37:0
cpu_38:0
cpu_39:0
Total :0
```

Sometimes, when loading the new configure file, and the new configure file does not match the old configure file, the `gtp-enhance-mode` status will be confused.

You can see :

```
#config system npu
#get
gtp-enhance-mode: enable
```

but you can also see that

```
diagnose npu np6 hbq-stats all
Total :0
```

This means the `gtp-enhance-mode` is actually set to `disable`.

The inverse is also possible, when you see

```
#config system npu
#get
gtp-enhance-mode: disable
```

but you also see that

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
...
cpu_39:0
Total :0
```

This means the `gtp-enhance-mode` is actually set to `enable`.

If these combinations occur, just run the command below:

```
config system npu
  set gtp-enhance-mode enable
end
```

or

```
config system npu
  set gtp-enhance-mode disable
end
```

Once this is done, reboot the device to let the 2 statuses match.

Configuring GTP on FortiOS Carrier

Configuring GTP support on FortiOS Carrier involves configuring a number of areas of features.

GTP support on the Carrier-enabled FortiGate unit

The FortiCarrier unit needs to have access to all traffic entering and exiting the carrier network for scanning, filtering, and logging purposes. This promotes one of two configurations — hub and spoke, or bookend.

A hub and spoke configuration with the Carrier-enabled FortiGate unit at the hub and the other GPRS devices on the spokes is possible for smaller networks where a lower bandwidth allows you to divide one unit into multiple virtual domains to fill multiple roles on the carrier network. It can be difficult with a single FortiOS Carrier as the hub to ensure all possible entry points to the carrier network are properly protected from potential attacks such as relayed network attacks.

A bookend configuration uses two Carrier-enabled FortiGate units to protect the carrier network between them with high bandwidth traffic. One unit handles traffic from mobile stations, SGSNs, and foreign carriers. The other handles GGSN and data network traffic. Together they ensure the network is secure.

The Carrier-enabled FortiGate unit can access all traffic on the network. It can also verify traffic between devices, and verify that the proper GPRS interface is being used. For example there is no reason for a Gn interface to be used to communicate with a mobile station — the mobile station will not know what to do with the data — so that traffic is blocked.

When you are configuring your Carrier-enabled FortiGate unit's GTP profile, you must first configure the APN. It is critical to GTP communications — no traffic will flow without the APN.

The Carrier-enabled FortiGate unit does more than just forward and route GTP packets over the network. It also performs:

- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)

Packet sanity checking

The FortiOS Carrier firewall checks the following items to determine if a packet confirms to the UDP and GTP standards:

- GTP release version number — must be 0, 1, or 2
- Settings of predefined bits
- Protocol type
- UDP packet length

If the packet in question does not confirm to the standards, the FortiOS Carrier firewall drops the packet, so that the malformed or forged traffic will not be processed.

GTP stateful inspection

Apart from the static inspection (checking the packet header), the FortiOS Carrier firewall performs stateful inspection.

Stateful inspection provides enhanced security by keeping track of communications sessions and packets over a period of time. Both incoming and outgoing packets are examined. Outgoing packets that request specific types of incoming packets are tracked; only those incoming packets constituting a proper response are allowed through the firewall.

The FortiOS Carrier firewall can also index the GTP tunnels to keep track of them.

Using the enhanced Carrier traffic policy, the FortiOS Carrier firewall can block unwanted encapsulated traffic in GTP tunnels, such as infrastructure attacks. Infrastructure attacks involve attempts by an attacker to connect to restricted machines, such as GSN devices, network management systems, or mobile stations. If these attempts to connect are detected, they are to be flagged immediately by the firewall .

Protocol anomaly detection and prevention

The FortiOS Carrier firewall detects and optionally drops protocol anomalies according to GTP standards and specific tunnel states. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of protocol specifications. These packets are not seen on a production network. Protocol anomaly attacks exploit poor programming practices when decoding packets, and are typically used to maliciously impair system performance or elevate privileges.

FortiOS Carrier also detects IP address spoofing inside GTP data channel.

See [Protocol anomaly detection and prevention](#).

GTP Shared Tunnel Limit

The GTP Shared Tunnel limit is the total number of GTP tunnels created by multiple GTP profiles. A Global shared tunnel limit gives the flexibility of limiting the number of GTP tunnels flowing through different profiles. A shared global limit is defined and then referenced in the profiles. Before FortiOS 6.0, the GTP tunnel limit could be set on a per-profile basis. The GTP tunnel limits can now be set per VDOM.

Per profile tunnel limiting is still possible but restrictive limits between the global limit and the profile limit will be enforced.

Example:

- Global shared tunnel limit defined as 12
- GTP Profile A - per profile tunnel limit defined as 8
- GTP Profile B - per profile tunnel limit defined as 14

You can have eight tunnels active in profile A, but the ninth will be dropped due to the profile limit of 8.

If Profile A still has eight active tunnels, you can have four tunnels active in profile B and the fifth will be dropped even though the profile allows fourteen, because the global share limit is twelve.

Configuring the GTP tunnel limit

The tunnel limit shaper is created/edited by configuring the object `config gtp tunnel-limit`.

Each GTP profile selects a shaper to use from the object configured in the CLI.

These values are shared by all of the profiles associated with the indicated shaper:

- Each GTP profile selects the shared tunnel limiter from the CLI.
- Each shared tunnel limiter counts the total number of alive GTP tunnels created by GTP profiles that select the limiter.
- Once the total number exceeds the shared limits, new tunnel requests of those GTP profiles will be rejected.

CLI syntax:

```
config gtp tunnel-limit
  edit "gtp-tl-1"
    set tunnel-limit <integer value from 1 to 16000000>
  end
```

Use the syntax below to assign the tunnel limit to the GTP profile.

CLI syntax:

```
config firewall gtp
  edit "gtp1"
    set global-tunnel-limit "gtp-tl-1"
  next
  edit "gtp2"
    set global-tunnel-limit "gtp-tl-1"
  end
```

Diagnose command

A diagnose command is available to show the shared tunnel limiters.

```
diagnose firewall gtp tunnel-limit list
```

Example output:

```
name=gtp-tl-1 tunnel_limit=50 tunnel_count=0
```

HA

FortiOS Carrier active-passive HA provides failover protection for the GTP tunnels. This means that an active-passive cluster can provide FortiOS Carrier firewall services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiOS Carrier firewall. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially for mission-critical environments.

FortiOS HA synchs TCP sessions by default, but UDP sessions are not synchronized by default. However synchronizing a session is only part of the solution if the goal is to continue GTP processing on a synchronized session after a HA switch. For that to be successful we also need to synch the GTP tunnel state. So, once the master completes tunnel setup then the GTP tunnel is synchronized to the slave.

GTP traffic will only flow without interruption on a HA switch if bidirectional GTP policies have been configured: an internal (GTP server) to external (all) UDP port GTP policy, and an external (all) to internal (GTP server) UDP port GTP policy. If either policy is missing then traffic may be interrupted until traffic flows in the opposite direction.

For more information on HA in FortiOS, see the High Availability (HA) Guide or the FortiOS Administration Guide.

Virtual domain support

FortiOS Carrier is suited to both large and smaller carriers. A single Carrier-enabled FortiGate unit can serve either one large carrier, or several smaller ones through virtual domains. As with any FortiGate unit, Carrier-enabled units have the ability to split their resources into multiple virtual units. This allows smaller carriers to use just the resources that they need without wasting the extra. For more information on HA in FortiOS, see the Virtual Domains (VDOMs) Guide.

Configuring General Settings on the Carrier-enabled FortiGate unit

To configure the GTP General Settings, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand **General Settings** to configure settings. See General settings options.

GTP Monitor Mode

The `monitor-mode` setting is part of the GTP profile. The setting shows on all GTP profiles and works for all GTP versions.

When this setting is enabled, if a GTP packet is to be dropped due to a GTP deny case such as:

- GTP_DENY
- GTP_RATE_LIMIT
- GTP_STATE_INVALID
- GTP_TUNNEL_LIMIT

instead of being dropped, it will be forwarded and logged with the original deny log message and a "-monitor" suffix (e.g., state-invalid-monitor).

This setting is found in the CLI.

```
config firewall gtp
edit profile_name
...
set monitor-mode {disable*|enable}
...
end
end
```

GTP Stats via SNMP

All parameters/values that can be checked with the following debug commands are available via SNMP:

- `diagnose firewall gtp stat`
- `diagnose firewall gtp runtime-stat`

The following OID was added to make GTP stats available via SNMP:

- 1.3.6.1.4.1.12356.101.5.3

The sequence of printed items of the debug commands was also adjusted to make it consistent with the data type and SNMP.

Configuring Encapsulated Filtering in FortiOS Carrier

Encapsulated traffic on the GPRS network can come in a number of forms as it includes traffic that is “wrapped up” in another protocol. This detail is important for firewalls because it requires “unwrapping” to properly scan the data inside. If encapsulated packets are treated as regular packets, that inside layer will never be scanned and may allow malicious data into your network.

On Carrier-enabled FortiGate units, GTP related encapsulated filtering falls under encapsulated IP traffic filtering, and encapsulated non-IP end user address filtering.

Configuring Encapsulated IP Traffic Filtering

Generally there are a very limited number of IP addresses that are allowed to encapsulate GPRS traffic. For example GTP tunnels are a valid type of encapsulation when used properly. This is the GTP tunnel which uses the Gp or Gn interfaces between SGSNs and GGSNs. However, a GTP tunnel within a GTP tunnel is not accessible — FortiOS Carrier will either block or forward the traffic, but is not able to open it for inspection.

The ability to filter GTP sessions is based on information contained in the data stream and provides operators with a powerful mechanism to control data flows within their infrastructure. You can also configure IP filtering rules to filter encapsulated IP traffic from Mobile Stations.

To configure the Encapsulated IP Traffic Filtering, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand **Encapsulated IP Traffic Filtering** to configure settings. See Encapsulated IP traffic filtering options.

When to use encapsulated IP traffic filtering

The following are the typical cases that need encapsulated IP traffic filtering:

Mobile station IP pools

In a well-designed network, best practices dictate that the mobile station address pool is to be completely separate from the GPRS network infrastructure range of addresses. Encapsulated IP packets originating from a mobile station will not contain source or destination addresses that fall within the address range of GPRS infrastructures. In addition, traffic originating from the users handset will not have destination/source IP addresses that fall within any Network Management System (NMS) or Charging Gateway (CG) networks.

Communication between mobile stations

Mobile stations on the same GPRS network are not able to communicate with other mobile stations. Best practices dictate that packets containing both source and destination addresses within the mobile station's range of addresses are to be dropped.

Direct mobile device or internet attacks

It may be possible for attackers to wrap attack traffic in GTP protocols and submit the resulting GTP traffic directly to a GPRS network element from their mobile stations or a node on the Internet. It is possible that the receiving SGSN or GGSN would then strip off the GTP header and attempt to route the underlying attack. This underlying attack could have any destination address and would probably have a source address spoofed as if it were valid from that PLMN.

You cannot add an IE removal policy when you are creating a new profile.

Relayed network attacks

Depending on the destination the attack could be directly routed, such as to another node of the PLMN, or re wrapped in GTP for transmission to any destination on the Internet outside the PLMN depending on the routing table of the GSN enlisted as the unwitting relay.

The relayed attack could have any source or destination addresses and could be any of numerous IP network attacks, such as an attack to hijack a PDP context, or a direct attack against a management interface of a GSN or other device within the PLMN. Best practices dictate that any IP traffic originating on the Internet or from an MS with a destination address within the PLMN is to be filtered.

Configuring Encapsulated Non-IP End User Address Filtering

Much of the traffic on the GPRS network is in the form of IP traffic. However some parts of the network do not use IP based addressing, so the Carrier-enabled FortiGate unit is unable to perform Encapsulated IP Traffic Filtering.

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications only list PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC 1700. The PDP

types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

To configure the Encapsulated Non-IP End User Address Filtering, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand **Encapsulated Non-IP End User Address Filtering** to configure settings. See Encapsulated non-IP end user traffic filtering options.

Configuring the Protocol Anomaly feature in FortiOS Carrier

When anomalies do happen, it is possible for the anomaly to interrupt network traffic or consume network resources — if precautions are not taken. Anomalies can be generated by accident or maliciously, but both methods can have the same results — degrading the performance of the carrier network, or worse.

To configure GTP protocol anomalies, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand the **Protocol Anomaly** option. See Protocol Anomaly prevention options.

The following are some examples:

- The GTP header specifies the length of the packet excluding the mandatory GTP header. In GTP version 0 (GSM 09.60), the mandatory GTP header size is 20 bytes, whereas GTP version 1 (GSM 29.060) specifies that the minimum length of the GTP header is 8 bytes. The GTP packet is composed of the header, followed by Information Elements typically presented in a Type-Length-Value format. It is possible for an attacker to create a GTP packet with a GTP header field length that is incompatible with the length of the necessary information elements.
- The same concepts are true for GTP version 2 headers even though there are different fields in them.
- It is similarly possible for an attacker to create a packet with an invalid IE length. Invalid lengths may cause protocol stacks to allocate incorrect amounts of memory, and thereby cause crashes or buffer overflows.

By default the FortiOS Carrier firewall detects these problems, as well as other protocol anomalies, and drops the packets. All protocol anomaly options are set to **Deny** by default. However, you can change the policy to allow them.

Configuring Anti-overbilling in FortiOS Carrier

GPRS over billing attacks can be prevented with a properly configured Carrier-enabled FortiGate unit.

Over billing can occur when a subscriber returns his IP address to the IP pool. Before the billing server closes it, the subscriber's session is still open and vulnerable. If an attacker takes control of the subscriber's IP address, he can send or receive data and the subscriber will be billed for the traffic.

Over billing can also occur when an available IP address is reassigned to a new mobile station (MS). Subsequent traffic by the previous MS may be forwarded to the new MS. The new MS would then be billed for traffic it did not initiate.

Anti-overbilling with FortiOS Carrier

The Carrier-enabled FortiGate unit can be configured to assist with anti-overbilling measures. These measures ensure that the customer is only billed for connection time and data transfer that they actually use.

Anti-overbilling on the Carrier-enabled FortiGate unit involves:

- the administrator configuring the over billing settings in the GTP profile to notify the Gi firewall when a GTP tunnel is deleted
- the unit clearing the sessions when the Gi firewall receives a notification from the Gn/Gp firewall about a GTP tunnel being deleted This way, the Gi firewall prevents over billing by blocking traffic initiated by other users.

The three locations to configure anti-overbilling options include:

- **Network > Interface** — Edit a specific interface. Towards the bottom of the **Edit Interface** page, in the **Status** section, you can toggle **Gi Gatekeeper**.
- **System > Settings** — In the **Gi Gatekeeper Settings** section, set the **Context ID** and **Port** that anti-overbilling will take place on.
- **Security Profiles > GTP Profile** — Edit a specific GTP Profile. In the **Anti-Overbilling** section, edit the **Gi Firewall IP address**, **Port**, **Interface** and **Security Context ID**, to use for anti-overbilling measures.

For detailed options, see [Anti-Overbilling options](#).

Logging events on the Carrier-enabled FortiGate unit

Logging on the Carrier-enabled FortiGate unit is just like logging on any other FortiOS unit. The only difference with FortiOS Carrier is that there are a few additional events that you can log beyond the regular ones. These additional events are covered here.

To change FortiOS Carrier specific logging event settings, go to **Security Profiles > GTP Profile** and edit a GTP profile. Expand the **Log** section to change the settings. For detailed options, see Log options.

The following information is contained in each log entry:

Timestamp	The time and date when the log entry was recorded
Source IP address	The sender's IP address.
Destination IP address	The receiver's IP address. The sender-receiver pair includes a mobile phone on the GPRS local network, and a device on a network external to the GPRS network, such as the Internet.
Tunnel Identifier (TID) Tunnel Endpoint Identifier (TEID)	An identifier for the start and endpoints of a GTP tunnel. This information uniquely defines all tunnels. It is important for billing information based on the length of time the tunnel was active and how much data passed over the tunnel.
Message type	For available message types, see Common message types on carrier networks.
Packet status	<p>What action was performed on the packet. This field matches the logging options while you are configuring GTP logging. See Logging events on the Carrier-enabled FortiGate unit on page 491.</p> <p>The status can be one of forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited</p>
Virtual domain ID or name	A Carrier-enabled FortiGate unit can be divided into multiple virtual units, each being a complete and self-contained virtual FortiCarrier unit. This field indicates which virtual domain (VDOM) was responsible for the log entry. If VDOMs are not enabled on your unit, this field will be <code>root</code> .
Reason to be denied if applicable	If the packet that generated this log entry was denied or blocked, this field will include what part of FortiOS denied or blocked that packet. Such as firewall, antivirus, webfilter, or spamfilter.

An example of the above log message format is for a Tunnel deleted log entry. When a tunnel is deleted, the log entry contains the following information:

- Timestamp
- Interface name (if applicable)
- SGSN IP address (source IP)
- GGSN IP address (destination IP)
- Tunnel ID
- Tunnel duration time in seconds
- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

GTP message type filtering

FortiOS Carrier supports message filtering in GTP by the type of message.

This section includes:

Common message types on carrier networks

Carrier networks include many types of messages — some concern the network itself, others are content moving across the network, and still others deal with handshaking, billing, or other administration based issues.

GTP contains two major parts GTP for the control plane (GTP-C) and GTP for user data tunnelling (GTP-U). Outside of those areas there are only unknown message types.

GTP-C messages

GTP-C contains the networking layer messages. These address routing, versioning, and other similar low level issues.

When a subscriber requests a Packet Data Protocol (PDP) context, the SGSN will send a create PDP context request GTP-C message to the GGSN giving details of the subscriber's request. The GGSN will then respond with a create PDP context response GTP-C message which will either give details of the PDP context actually activated or will indicate a failure and give a reason for that failure. This is a UDP message on port 212.

GTP-C message types include Path Management Messages, Location Management Messages, and Mobility Management Messages.

Path Management Messages

Path management is used by one GSN to detect if another GSN is alive, or if it has restarted after a failure.

The path management procedure checks if a given GSN is alive or has been restarted after a failure. In case of SGSN restart, all MM and PDP contexts are deleted in the SGSN, since the associated data is stored in a volatile memory. In the case of GGSN restart, all PDP contexts are deleted in the GGSN.

Tunnel Management Messages

The tunnel management procedures are used to create, update, and delete GTP tunnels in order to route IP PDUs between an MS and an external PDN via the GSNs.

The PDP context contains the subscriber's session information when the subscriber has an active session. When a mobile wants to use GPRS, it must first attach and then activate a PDP context. This allocates a PDP context data structure in the SGSN that the subscriber is currently visiting and the GGSN serving the subscriber's access point.

Tunnel management procedures are defined to create, update, and delete tunnels within the GPRS backbone network. A GTP tunnel is used to deliver packets between an SGSN and a GGSN. A GTP tunnel is identified in each GSN node by a TEID, an IP address, and a UDP port number.

Location Management Messages

The location-management procedure is performed during the network-requested PDP context activation procedure if the GGSN does not have an SS7 MAP interface (i.e., Gc interface). It is used to transfer location

messages between the GGSN and a GTP-MAP protocol-converting GSN in the GPRS backbone network.

Location management subprocedures are used between a GGSN that does not support an SS7 MAP interface (i.e., Gc interface) and a GTP-MAP protocol-conversing GSN. This GSN supports both Gn and Gc interfaces and is able to perform a protocol conversing between GTP and MAP.

Mobility Management Messages

The MM procedures are used by a new SGSN in order to retrieve the IMSI and the authentication information or MM and PDP context information in an old SGSN. They are performed during the GPRS attach and the inter-SGSN routing update procedures.

The MM procedures are used between SGSNs at the GPRS-attach and inter-SGSN routing update procedures. An identity procedure has been defined to retrieve the IMSI and the authentication information in an old SGSN. This procedure may be performed at the GPRS attach. A recovery procedure enables information related to MM and PDP contexts in an old SGSN to be retrieved. This procedure is started by a new SGSN during an inter-SGSN RA update procedure.

GTP-U messages

GTP-U is focused on user related issues including tunneling, and billing. GTP-U message types include MBMS messages, and GTP-U and Charging Management Messages

MBMS messages

Multimedia Broadcast and Multicast Services (MBMS) have recently begun to be offered over GSM and UMTS networks on UTRAN and GERAN radio access technologies. MBMS is mainly used for mobile TV, using up to four GSM timeslots for one MBMS connection. One MBMS packet flow is replicated by GGSN, SGSN and RNCs.

MBMS is split into the MBMS Bearer Service and the MBMS User Service. The MBMS User Service is basically the MBMS Service Layer and offers a Streaming- and a Download Delivery Method. The Streaming Delivery method can be used for continuous transmissions like Mobile TV services. The Download Method is intended for "Download and Play" services.

GTP-U and Charging Management Messages

SGSNs and GGSNs listen for GTP-U messages on UDP port 2152.

GTP' (GTP prime) is used for billing messages. It uses the common GTP messages (GTP Version Not Supported, Echo Request and Echo Response) and adds additional messages related to billing procedures.

Unknown Action messages

If the system doesn't know what type of message it is, it falls into this category. This is an important category of message because malformed messages may appear and need to be handled with security in mind.

Fortinet best practices dictate that you set **Unknown Action messages** to deny for security reasons.

Configuring message type filtering in FortiOS Carrier

GPRS Tunneling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) traffic within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling.

In the CLI, there is a keyword for each type of GTP message for both message filtering, and for message rate limiting.

GTP message rate limiting is only accessible from the CLI using the command `configure firewall gtp`.

To configure GTP message type filtering - web-based manager

1. Go to **Security Profiles > GTP Profile**.
2. Select **Create New**.
3. Enter a name for this profile such as `msg_type_filtering`.
4. Select **Message Type Filtering** to expand it.
5. For each type of message in the list, select Allow or Deny. All messages are set to Allow by default.

Fortinet best practices dictate that the unknown message action should be set to **Deny** for security reasons as this will block malformed messages.

6. Optionally select and configure any other GTP features for this profile, such as logging.
7. Select **OK** to save the profile.
8. Apply the `msg_type_filtering` profile a security policy configured for GTP tunnel traffic.

To configure GTP message filtering and block Unknown Message Action messages- CLI

```
config firewall gtp
  edit msg_type_filtering
    config message-filter
      set unknown-message-action deny
    next
  end
end
```

Message Type Fields

Each of the following message types can be allowed or denied by your Carrier-enabled FortiGate unit depending on your carrier network and GTP traffic.

Unknown Message Action

Set this message type to deny.

Many attempts to hack into a carrier network will result in this unknown message type and therefore it is denied for security reasons.

Path Management Messages

Message Type	Used by	Description
Echo Request/Response	GTP-C, GTP-U, GTP'	Echo Request is sent on a path to another GSN to determine if the other node is alive. Echo Response is the reply.
Version not Supported	GTP-C, GTP-U, GTP'	There are multiple versions of GTP. Both devices communicating must use the same version of GTP, or this message will be the response.
Support Extension Headers Notification		Extensions are optional parts that a device can choose to support or not. If a device includes these extensions, it must include headers for the extensions to sure ensure proper formatting.

Tunnel Management Messages

Message Type	Used by	Description
Create PDP Context Request/ Response	GTP-C	Sent from an SGSN to a GGSN node as part of a GPRS PDP Context Activation procedure or the Network-Requested PDP Context Activation procedure. A valid request initiates the creation of a tunnel.
Update PDP Context Request/ Response	GTP-C	Used when PDP Context information changes, such as when a mobile device changes location.
Delete PDP Context Request/ Response	GTP-C	Used to terminate a PDP Context, and confirm the context has been deleted.
Create AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS Anonymous Access PDP Context Activation. It is used to create a tunnel between a context in the SGSN and a context in the GGSN.
Delete AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS PDP Anonymous Access Context Deactivation procedure to deactivate an activated PDP Context. It contains Cause and Private Extension Information Elements

Message Type	Used by	Description
Error Indication	GTP-U	<p>Sent to the GGSN when a tunnel PDU is received for the following conditions:</p> <ul style="list-style-type: none"> — No PDP context exists — PDP context is inactive — No MM context exists — GGSN deletes its PDP context when the message is received.
PDU Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	<p>When receiving a Tunneled PDU (T-PDU), the GGSN checks if a PDP context is established for the given PDP address. If no PDP context has been established, the GGSN may initiate the Network-requested PDP Context Activation procedure by sending a PDU Notification Request to the SGSN.</p> <p>Reject Request - Sent when the PDP context requested by the GGSN cannot be established.</p>

Location Management Messages

Message Type	Used By	Description
Send Routing Information for GPRS Request/ Response	GTP-C	Sent by the GGSN to obtain location information for the MS. This message type contains the IMSI of the MS and Private Extension.
Failure Report Request/ Response	GTP-C	<p>Sent by the GGSN to the HLR when a PDU reject message is received.</p> <p>The GGSN requests the HLR to set the flag and add the GGSN to the list of nodes to report to when activity from the subscriber that owns the PDP address is detected.</p> <p>The message contains the subscriber IMSI and Private Extension</p>
Note MS GPRS Present Request/ Response	GTP-C	<p>When the HLR receives a message from a mobile with MDFG set, it clears the MDFG and sends the Note MS Present message to all GGSN's in the subscriber's list.</p> <p>This message type contains subscriber IMSI, GSN Address and Private Extension</p>

Mobility Management Messages

Message Type	Used By	Description
Identification Request/Response	GTP-C	Sent by the new SGSN to the old SGSN to request the IMSI for a MS when a GPRS Attach is done with a P-TMSI and the MS has changed SGSNs since the GPRS Detach was done.
SGSN context Request/ Response/ Acknowledge	GTP-C	Sent by the new SGSN to the old SGSN to request the MM and PDP Contexts for the MS.
Forward Relocation Request/ Response/ Complete/ Complete Acknowledge	GTP-C	<p>Indicates mobile activation/deactivation within a Routing Area. This prevents paging of a mobile that is not active (visited VLR rejects calls from the HLR or applies Call Forwarding). Note that the mobile station does not maintain an attach/detach state.</p> <p>SRNS contexts contain for each concerned RAB the sequence numbers of the GTP-PDUs next to be transmitted in uplink and downlink directions.</p>
Relocation Cancel Request/ Response	GTP-C	Send to cancel the relocation of a connection.
Forward SRNS Context/ Context Acknowledge	GTP-C	This procedure may be used to trigger the transfer of SRNS contexts from RNC to CN (PS domain) in case of inter system forward handover.
RAN Information Relay	GTP-C	<p>Forward the Routing Area Network (RAN) information.</p> <p>A Routing Area (RA) is a subset of a GSM Location Area (LA). A RA is served by only one SGSN. Ensures that regular radio contact is maintained by the mobile</p>

MBMS messages

Message Type	Used By	Description
MBMS Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	Notification of the radio access devices.
Create MBMS Context Request/ Response	GTP-C	<p>Request to create an active MBMS context. The context will be pending until the response is received.</p> <p>Once active, the MBMS context allows the MS to receive data from a specific MBMS source</p>

Message Type	Used By	Description
Update MBMS Context Request/ Response	GTP-C	
Delete MBMS Context Request/ Response	GTP-C	Request to deactivate the MBMS context. When the response is received, the MBMS context will be inactive.

GTP-U and Charging Management Messages

Message Type	Used By	Description
G-PDU	GTP-C, GTP-U	GPRS Packet data unit delivery message.
Node Alive Request/Response	GTP-C, GTP-U	Used to inform rest of network when a node starts service.
Redirection Request/Response	GTP-C, GTP-U	Used to divert the flow of CDRs from the CDFs to another CGF when the sender is being removed, or they are used when the CGF has lost its connection to a downstream system.
Data Record Transfer Request/Response	GTP-C, GTP-U	Used to reliably transport CDRs from the point of generation (SGSN/GGSN) to non-volatile storage in the CGF

GTP identity filtering

FortiOS Carrier supports a number of filtering methods based on subscriber identity such as APN filtering, IMSI filtering, and advanced filtering.

This section includes:

IMSI on carrier networks

The International Mobile Subscriber Identity (IMSI) number is central to identifying users on a carrier network. It is a unique number that is assigned to a cell phone or mobile device to identify it on the GSM or UTM network.

Typical the IMSI number is stored on the SIM card of the mobile device and is sent to the network as required.

An IMSI number is 15 digits long, and includes the Mobile Country Code (MCC), Mobile Network Code (MNC), and Mobile Station Identification Number (MSIN).

IMSI codes

The Home Network Identity (HNI) is made up of the MCC and MNC. The HNI is used to fully identify a user's home network. This is important because some large countries have more than one country code for a single carrier. For example a customer with a mobile carrier on the East Coast of the United States would have a different MCC than a customer on the West Coast with the same carrier because even though the MNC would be the same the MCC would be different — the United States uses MCCs 310 to 316 due to its size.

If an IMSI number is not from the local carrier's network, IMSI analysis is performed to resolve the number into a Global Title which is used to access the user's information remotely on their home carrier's network for things like billing and international roaming.

Other identity and location based information elements

IMSI focuses on the user, their location, and carrier network. There are other numbers used to identify different user related Information Elements (IE).

These identity and location based elements include:

- Access Point Number (APN)
- Mobile Subscriber Integrated Services Digital Network (MSISDN)
- Radio Access Technology (RAT) type
- User Location Information (ULI)
- Routing Area Identifier (RAI)
- International Mobile Equipment Identity (IMEI)

Access Point Number (APN)

The Access Point Number (APN) is used in GPRS networks to identify an IP packet data network that a user wants to communicate with. The Network Identifier describes the network and optionally the service on that network that the GGSN is connected to. The APN also includes the MCC and MCN, which together locate the network the GGSN belongs to. An example of an APN in the Barbados using Digicel as the carrier that is connecting to the Internet is `internet.mcc342.mnc750.gprs`.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

The access point can then be used in a DNS query to a private DNS network. This process (called APN resolution) gives the IP address of the GGSN which serves the access point. At this point a PDP context can be activated.

Mobile Subscriber Integrated Services Digital Network (MSISDN)

This is a 15-digit number that, along with the IMSI, uniquely identifies a mobile user. Normally this number includes a 2-digit country code, a 3-digit national destination code, and a 10-digit subscriber number or the phone number of the mobile device, and because of that may change over time if the user changes their phone number. The MSISDN number follows the ITU-T E.164 numbering plan.

Radio Access Technology (RAT) type

The RAT type represents the radio technology used by the mobile device. This can be useful in determining what services or content can be sent to a specific mobile device. FortiOS Carrier supports:

- **UMTS Terrestrial Radio Access Network (UTRAN)**, commonly referred to as 3G, routes many types of traffic including IP traffic. This is one of the faster types.
- **GSM EDGE Radio Access Network (GERAN)** is a key part of the GSM network which routes both phone calls and data.
- **Wireless LAN (WLAN)** is used but not as widely as the other types. It is possible for the mobile device to move from one WLAN to another such as from an internal WLAN to a commercial hot spot.
- **Generic Access Network (GAN)** can also be called unlicensed mobile access (UMA). It routes voice, data, and SIP over IP networks. GAN is commonly used for mobile devices that have a dual-mode and can hand-off between GSM and WLANs.
- **High Speed Packet Access (HSPA)** includes two other protocols High Speed Downlink and Uplink Packet Access protocols (HSDPA and HSUPA respectively). It improves on the older WCDMA protocols by better using the radio bandwidth between the mobile device and the radio tower. This results in an increased data transfer rate for the user.

RAT type is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

User Location Information (ULI)

Gives Cell Global Identity/Service Area Identity (CGI/SAI) of where the mobile station is currently located. The ULI and the RAI are commonly used together to identify the location of the mobile device.

ULI is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

Routing Area Identifier (RAI)

Routing Areas (RAs) divide the carrier network and each has its own identifier (RAI). When a mobile device moves from one routing area to another, the connection is handled by a different part of the network. There are normally multiple cells in a routing area. There is only one SSGN per routing area. The RAI and ULI are commonly used to determine a user's location.

RAI is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

International Mobile Equipment Identity (IMEI)

IMEI is a unique 15-digit number used to identify mobile devices on mobile networks. It is very much like the MAC address of a TCP/IP network card for a computer. It can be used to prevent network access by a stolen phone — the carrier knows the mobile phone's IMEI, and when it is reported stolen that IMEI is blocked from accessing the carrier network no matter if it has the same SIM card as before or not. It is important to note that the IMEI stays with the mobile phone or device where the other information is either location based or stored on the removable SIM card.

IMEI type is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

When to use APN, IMSI, or advanced filtering

At first glance APN, IMSI, and advanced filtering have parts in common. For example two can filter on APN, and another two can filter on IMSI. The difficulty is knowing when to use which type of filtering.

Identity filtering comparison

Filtering type	Filter on the following data:	When to use this type of filtering
APN	APN	Filter based on GTP tunnel start or destination
IMSI	IMSI, MCC-MNC	Filter based on subscriber information
Advanced	PDP context, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI	When you want to filter based on: <ul style="list-style-type: none"> • user phone number (MSISDN) • what wireless technology the user employed • to get on the network (RAT type) • user location (ULI and RAI) • handset ID, such as for stolen phones (IMEI)

APN filtering is very specific — the only identifying information that is used to filter is the APN itself. This will always be present in GTP tunnel traffic, so all GTP traffic can be filtered using this value.

IMSI filtering can use a combination of the APN and MCC-MNC numbers. The MCC and MNC are part of the APN, however filtering on MCC-MNC separately allows you to filter based on country and carrier instead of just the destination of the GTP Tunnel.

Advanced filtering can go into much deeper detail covering PDP contexts, MSISDN, IMEI, and more not to mention APN, and IMSI as well. If you can't find the information in APN or IMSI that you need to filter on, then use Advanced filtering.

Configuring APN filtering in FortiOS Carrier

To configure APN filtering go to **Security Profiles > GTP Profile**. Select a profile or create a new one, and expand **APN filtering**.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

Enable APN Filter	Select to enable filtering based on APN value.
Default APN Action	Select either Allow or Deny for all APNs that are not found in the list. The default is Allow.
Value	Displays the APN value for this entry. Partial matches are allowed using wildcard. For example <code>*.mcc333.mcn111.gprs</code> would match all APNs from country 333 and carrier 111 on the gprs network.
Mode	<p>Select one or more of the methods used to obtain APN values.</p> <p>Mobile Station provided - The APN comes from the mobile station where the mobile device connected. This is the point of entry into the carrier network for the user's connection.</p> <p>Network provided - The APN comes from the carrier network.</p> <p>Subscription Verified - The user's subscription has been verified for this APN. This is the most secure option.</p>
Action	One of allow or deny to allow or block traffic associated with this APN.
Delete icon	Select to remove this APN entry from the list.
Edit icon	Select to change the information for this APN entry.
Add APN	<p>Select to add an APN to the list. Not active while creating GTP profile, only when editing an existing GTP profile.</p> <p>Save all changes before adding APNs. A warning to this effect will be displayed when you select the Add APN button.</p>

The Add APN button is not activated until you save the new GTP profile. When you edit that GTP profile, you will be able to add new APNs.

Configuring IMSI filtering in FortiOS Carrier

In many ways the IMSI on a GPRS network is similar to an IP address on a TCP/IP network. Different parts of the number provide different pieces of information. This concept is used in IMSI filtering on FortiOS Carrier.

To configure IMSI filtering go to **Security Profiles > GTP Profile** and expand **IMSI filtering**.

While both the APN and MCC-MCN fields are optional, without using one of these fields the IMSI entry will not be useful as there is no information for the filter to match.

Enable IMSI Filter	Select to turn on IMSI filtering.
Default IMSI Action	<p>Select Allow or Deny. This action will be applied to all IMSI numbers except as indicated in the IMSI list that is displayed.</p> <p>The default value is Allow.</p>
APN	<p>The Access Point Number (APN) to filter on.</p> <p>This field is optional.</p>
MCC-MNC	<p>The Mobile Country Code (MCC) and Mobile Network Code (MNC) to filter on. Together these numbers uniquely identify the carrier and network of the GGSN being used.</p> <p>This field is optional.</p>
Mode	<p>Select the source of the IMSI information as one or more of the following:</p> <p>Mobile Station provided - the IMSI number comes from the mobile station the mobile device is connecting to.</p> <p>Network provided - the IMSI number comes from the GPRS network which could be a number of sources such as the SGSN, or HLR.</p> <p>Subscription Verified - the IMSI number comes from the user's home network which has verified the information.</p> <p>While Subscription Verified is the most secure option, it may not always be available. Selecting all three options will ensure the most complete coverage.</p>
Action	Select the action to take when this IMSI information is encountered. Select one of Allow or Deny.
Delete Icon	Select the delete icon to remove this IMSI entry.
Edit Icon	Select the edit icon to change information for this IMSI entry.
Add IMSI	<p>Select to add an IMSI to the list. Not active while creating GTP profile, only when editing an existing GTP profile.</p> <p>Save all changes before adding IMSIs. A warning to this effect will be displayed when you select the Add IMSI button.</p>

Configuring advanced filtering in FortiOS Carrier

Compared to ADN or IMSI filtering, advanced filtering is well named. Advanced filtering can be viewed as a catch-all filtering option — if ADN or IMSI filtering doesn't do what you want, then advanced filtering will. The advanced filtering can use more information elements to provide considerably more granularity for your filtering.

Enable	Select to turn on advanced filtering.
Default Action	Select Allow or Deny as the default action to take when traffic does not match an entry in the advanced filter list .
Messages	<p>Optionally select one or more types of messages this filter applies to:</p> <p>Create PDP Context Request, Create PDP Context Response, Update PDP Context Request, or Update PDP Context Response.</p> <p>Selecting Create PDP Context Response or Update PDP Context Response limits RAT type to only GAN and HSPA, and disables the APN, APN Mode, IMSI, MSISDN, ULI, RAI, and IMEI fields.</p> <p>To select Update PDP Context Request, APN Restriction must be set to all. Selecting Update PDP Context Request disables the APN, MSISDN, and IMEI fields.</p> <p>if all message types are selected, only the RAT Types of GAN and HSPA are available to select.</p>
APN Restriction	APN Restriction either allows all APNs or restricts the APNs to one of four categories — Public-1, Public-2, Private-1, or Private-2. This can also be combined with a specific APN or partial APN as well as specifying the APN mode.
RAT Type	Select one or more of the Radio Access Technology Types listed. These fields control how a user accesses the carrier's network. You can select one or more of UTRAN, GERAN, WLAN, GAN, HSPA, or any.
ULI	<p>The user location identifier. Often the ULI is used with the RAI to locate a user geographically on the carrier's network.</p> <p>The ULI is disabled when Create PDP Context Response or Update PDP Context Response messages are selected.</p>
RAI	<p>The router area identifier. There is only one SGSN per routing area on a carrier network. This is often used with ULI to locate a user geographically on a carrier network.</p> <p>The RAI is disabled when Create PDP Context Response or Update PDP Context Response messages are selected.</p>

IMEI	<p>The International Mobile Equipment Identity. The IMEI uniquely identifies mobile hardware, and can be used to block stolen equipment.</p> <p>The IMEI is only available when Create PDP Context Request or no messages are selected.</p>
Action	<p>Select Allow or Deny as the action when this filter matches traffic.</p> <p>The default is Allow.</p>
Delete Icon	Select to delete this entry from the list.
Edit Icon	Select to edit this entry.
Add	<p>Select to add an advanced filter to the list. Not active while creating GTP profile, only when editing an existing GTP profile.</p> <p>Save all changes before adding advanced filters. A warning to this effect will be displayed when you select the Add button.</p>

SCTP Concepts

As of FortiOS version 5.0, the FortiGate natively handles SCTP (Stream Control Transport Protocol) traffic, as an alternative to TCP and UDP for use in Carrier networks. The FortiGate handles SCTP as if it would any other traffic.

Overview

SCTP is a connection-oriented transport protocol that overcomes some of the limitations of both TCP and UDP that prevent reliable transfer of data over IP-based networks (such as those used by telephony systems and carrier networks). The 'Stream' in SCTP refers to the sequence of user messages or packets that are considered at the same time to be individual objects and also treated as a whole by networked systems. SCTP is less vulnerable to congestion and flooding due to more advanced error handling and flood protection built into the protocol.

SCTP features as compared to TCP and UDP

Feature	SCTP	TCP	UDP
State required at each endpoint	yes	yes	no
Reliable data transfer	yes	yes	no
Congestion control and avoidance	yes	yes	no
Message boundary conservation	yes	no	yes

Feature	SCTP	TCP	UDP
Path MTU discovery and message fragmentation	yes	yes	no
Message bundling	yes	yes	no
Multi-homed hosts support	yes	no	no
Multi-stream support	yes	no	no
Unordered data delivery	yes	no	yes
Security cookie against SYN flood attack	yes	no	no
Built-in heartbeat (reachability check)	yes	no	N/A

All of these features are built into the design of the Protocol, and the structure of SCTP packets and networks. The FortiGate unit interprets the traffic and provides the necessary support for maintenance and verification features, but the features are not FortiGate specific. These features are documented in greater detail below.

State required at each endpoint

Constant back and forth acknowledgement and content verification messages are sent between all SCTP peer endpoints, and all endpoints' state machine actions must be synchronized for traffic to flow.

Reliable data transfer

SCTP places data and control information (eg. source, destination, verification) into separate messages, both sharing the same header in the same SCTP packet. This allows for constant verification of the contained data at both ends and along the path, preventing data loss or fragmentation. As well, data is not sent in an interruptible stream as in TCP.

Congestion control and avoidance

Built-in, constantly updating path detection and monitoring automatically redirect packets along alternate paths in case of traffic congestion or inaccessible destinations. For deliberate/malicious congestion control, see the below section on [Security cookie against SYN flood attack](#).

Message boundary conservation

SCTP is designed in such a way that no matter how messages are divided, redirected, or fragmented, the message boundaries will be maintained within the packets, and all messages cannot be appended without tripping verification mechanisms.

Path MTU discovery and message fragmentation

SCTP is capable of Path Maximum Transmission Unit discovery, as outlined in RFC4821. Two specific alterations have been made to how SCTP handles MTU. First, that endpoints will have separate MTU estimates for each possible multi-homed endpoint. Second, that bundled message fragments (as explained below) will be directed based on MTU calculations, so that retransmissions (if necessary) will be sent without delay to alternate addresses.

Message bundling

SCTP is a message-oriented protocol, which means that despite being a streaming data protocol, it transports a sequence of specific messages, rather than transporting a stream of bytes (like TCP). Since some data transmissions are small enough to not require a complete message's worth of content, so multiple pieces of content will be transmitted simultaneously within the messages.

Multi-homed hosts support

SCTP supports multi-homing, which is a network structure in which one or multiple sources/destinations has more than one IP address. SCTP can adapt to multi-homing scenarios and redirect traffic to alternate IP addresses in case of failure.

Multi-stream support

Due to the message bundling feature allowing for multiple pieces of content to be sent in messages at once, SCTP can 'multi-stream' content, by deliberately dividing it among messages at a fixed rate, so that multiple types of content (eg. both images and text) can be loaded at once, at the same pace.

Unordered data delivery

With control messages in every packet to provide verification of any packet's data and its place in the stream, the data being transmitted can actually arrive in any order, and verify that all has arrived or that some is missing.

Security cookie against SYN flood attack

Since every packet contains verification of its place in the stream, it makes it easy for the protocol to detect when redundant, corrupted or malicious packets flood the path, and they are automatically dropped when necessary.

Built-in heartbeat (reachability check)

Endpoints automatically send specific control chunks among the other SCTP packet information to peer endpoints, to determine the reachability of the destination. Heartbeat acknowledgement packets are returned if the destination is available.

SCTP Firewall

FortiGate stateful firewalls will protect and inspect SCTP traffic, according to RFC4960. SCTP over IPsec VPN is also supported. The FortiGate device is inserted as a router between SCTP endpoints. It checks SCTP Syntax for the following information:

- Source and destination port
- Verification Tag
- Chunk type, chunk flags, chunk length
- Sequence of chunk types
- Associations

The firewall also oversees and maintains several SCTP security mechanisms:

- SCTP four-way handshake
- SCTP heartbeat
- NAT over SCTP

The firewall has IPS DoS protection against known threats to SCTP traffic, including INIT/ACK flood attacks, and SCTP fuzzing.

Troubleshooting

This section offers troubleshooting options for Carrier-related issues.

This section includes:

FortiOS Carrier diagnose commands

This section includes diagnose commands specific to FortiOS Carrier features such as GTP.

GTP related diagnose commands

This CLI command allows you to gain information on GTP packets, logs, statistics, and other information.

```
diag firewall gtp <command>
```

apn list <gtp_profile>	The APN list entries in the specified GTP profile
auth-ggsns show <gtp_profile>	The authorized GGSNs entries for the specified GTP profile. Any GGSNs not on this list will not be recognized.
auth-sgsns show <gtp_profile>	The authorized SGSNs list entries for the specified GTP profile. Any SGSNs not on this list will not be recognized.
handover-grp show <gtp_profile>	The handover group showing the range of allowed handover group IP addresses. The handover group acts like a white list of allowed GTP addresses with a default deny at the end — if the GTP address is not on the list, it is denied.
ie-remove-policy list <gtp_profile>	List of IE policies in the IE removal policy for this GTP profile. The information displayed includes the message count for this policy, the length of the SGSN, the list of IEs, and list of SGSN IP addresses.
imsi list <gtp_profile>	IMSI filter entries for this GTP profile. The information displayed includes the message count for this filter, length of the IMSI, the length of the APN and IMSI, and of course the IMSI and APN values.
invalid-sgsns-to-long list <gtp_profile>	List of SGSNs that do not match the filter criteria. These SGSNs will be logged.
ip-policy list <gtp_profile>	List the IP policies including message count for each policy, the action to take, the source and destination IP addresses or ranges, and masks.
noip-policy <gtp_profile>	List the non-IP policies including the message count, which mode, the action to take, and the start and end protocols to be used by decimal number.

	Select list or flush.
path {list flush}	List the GTP related paths in FortiOS Carrier memory. Flush the GTP related paths from memory.
policy list <gtp_policy>	The GTP advanced filter policy information for this GTP profile. The information displayed for each entry includes a count for messages matching this filter, a hexadecimal mask of which message types to match, the associated flags, action to take on a match, APN selection mode, MSISDN, RAT types, RAI, ULI, and IMEI.
profile list	Displays information about the configured GTP profiles. You will not be able to see the bulk of the information if you do not log the output to a file.
runtime-stat flush	Select to flush the GTP runtime statistics from memory.
stat	Display the GTP runtime statistics — details on current GTP activity. This information includes how many tunnels are active, how many GTP profiles exist, how many IMSI filter entries, how many APN filter entries, advanced policy filter entries, IE remove policy filter entries, IP policy filter entries, clashes, and dropped packets.
tunnel {list flush}	Select one of list or flush. List lists all the GTP tunnels currently active. Flush clears the list of active GTP tunnels. This does not clear the clash counter displayed in the <code>stat</code> command.

Applying IPS signatures to IP packets within GTP-U tunnels

GTP-U (GTP user data tunnelling) tunnels carry user data packets, signaling messages and error information. GTP-U uses UDP port 2152. Carrier-enabled FortiGate units can apply IPS intrusion protection and detection to GTP-U user data sessions.

To apply IPS to GTP-U user data sessions, add an IPS Sensor to a profile and add the profile to a security policy that accepts GTP-U tunnels. The security policy Service field must be set to GTP or ANY to accept GTP-U packets.

The Carrier-enabled FortiGate unit intercepts packets with destination port 2152, removes the GTP header and handles the packets as regular IP packets. Applying an IPS sensor to the IP packets, the Carrier-enabled FortiGate unit can log attacks and pass or drop packets depending on the configuration of the sensor.

If the packet is GTP-in-GTP, or a nested tunnel, the packets are passed or blocked without being inspected.

To apply an IPS sensor to GTP-U tunnels

1. Go to **Security Profiles > Intrusion Protection** and select Create New (+) to add an IPS Sensor.
2. Configure the IPS Sensor to detect attacks and log, drop, or pass attack packets.

See the Intrusion Protection section of the [FortiOS UTM Guide](#).

3. Go to **Policy & Objects > IPv4 Policy** and apply the IPS sensor to the security policy.
4. Go to **Policy & Objects > IPv4 Policy** and select Create New to add a security policy or select a security policy.
5. Configure the security policy to accept GTP traffic.
In the security policy configure the source and destination settings to match the GTP traffic. Service to GTP or ANY so that the security policy accepts GTP traffic.
6. Select the GTP profile within the security policy.
7. Configure any other required security policy settings.
8. Select **OK** to save the security policy.

GTP packets are not moving along your network

When GTP packets are not getting to their destination, this could be caused by any one of a number of issues. General troubleshooting principals apply here.

The following sections provide some suggestions on how to troubleshoot this issue:

- [Attempt to identify the section of your network with the problem](#)
- [Ensure you have an APN configured](#)
- [Check the logs and adjust their settings if required](#)
- [Check the routing table](#)
- [Perform a sniffer trace](#)
- [Generate specific packets to test the network](#)

Attempt to identify the section of your network with the problem

The first step is to determine how widespread this problem is. Does it affect the whole GPRS network, or just one or two devices?

If the entire network is has this problem, the solution is likely a more general one such as ensuring the security policies allow GTP traffic to pass, the GTP profile specifies SSGNs and GSGNs, or ensuring the GTP general settings are not overly limiting.

If one part of the network is affected, the problem is more likely centered around configurations with those network devices specified such as the handover group, or authorized SGSNs/GGSNs. It is also possible that small portions of the network may have hardware related issues such as cabling or faulty hardware. This section does not address those issues, and assumes hardware is not the problem.

The handover group is a white list of GTP addresses allowed to handle GTP messages. If a device's address is not on this list, it will be denied.

Ensure you have an APN configured

When you configure your GTP profile, ensure you first configure the APN. Without it, there will be no flow of traffic. The APN is used in nearly all GTP communications and without it, the Carrier-enabled FortiGate unit doesn't have the information it needs.

Check the logs and adjust their settings if required

During normal operation, the log settings will show any problems on the network but may not provide the level of details required to fully troubleshoot the problem. The reason for this is that the level of detail required for troubleshooting would quickly overwhelm the daily logs without any real benefit.

GTP related events in the event log will have message IDs in the range 41216 to 41222. For more information on GTP log messages, see the Log Message Reference. For more information on logging in general, see the Logging and Reporting guide.

Once there is a problem to troubleshoot, check the logs to trace the traffic patterns and narrow down the possible sources of the problem. There may be enough detail for you to locate and fix the problem without changing the log settings.

Remember to set any changes you made to the log settings back to their original values when you are done troubleshooting. Otherwise, the amount of detail will overwhelm your logging.

However, if more detail is required you can change settings such as:

- Lower the Log Frequency number in GTP Profiles so fewer or no log messages are dropped. This will allow a more accurate picture of everything happening on the network, where you may have had only a partial picture before.
- Ensure all the GTP log events are enabled to provide you with a complete picture.
- Ensure that all relevant event types are enabled under **Log & Report > Log Config > Log Settings**.

For more information on GTP related logging, see Logging events on the Carrier-enabled FortiGate unit.

General information to look for in the logs includes:

- Are all packets having problems or just certain types?
- Are all devices on the network having problem, or just certain devices?
- Is it just GTP traffic that is having problems or are all types of traffic having the same problem?

Check the routing table

On any network, the routing table determines how packets reach their destination. This is also true on a carrier network.

If the Carrier-enabled FortiGate unit is running in NAT mode, verify that all desired routes are in the routing table — local subnets, default routes, specific static routes, and dynamic routing protocols. For complete information, it is best to check the routing table in the CLI. This method provides more complete information.

If VDOMs are enabled on your Carrier-enabled FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To check the routing table using the CLI

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
```

```
* - candidate default

S* 0.0.0.0/0 [10/0] via 192.168.183.254, port2
S 1.0.0.0/8 [10/0] via 192.168.183.254, port2
S 2.0.0.0/8 [10/0] via 192.168.183.254, port2
C 10.142.0.0/23 is directly connected, port3
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry from the routing table above:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

Perform a sniffer trace

When troubleshooting network traffic, it helps to look inside the headers of packets to determine if they are traveling along the route you expect. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your Carrier-enabled FortiGate unit has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, disable offloading on those interfaces.

What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the Carrier-enabled FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the Carrier-enabled FortiGate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing. This prevents an IP packet from being forwarded if its source IP address either does not belong to a locally attached subnet (local interface), or be a hop on the routing between the FortiOS Carrier and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the Carrier-enabled FortiGate unit and consequently cause many features to be turned off.

If you configure virtual IP addresses on your Carrier-enabled FortiGate unit, the unit will use those addresses in preference to the physical IP addresses. If not configured properly, secondary IP addresses can cause a broadcast storm. You will notice the secondary address being preferred when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as <code>port1</code> or <code>internal</code> . This can also be <code>any</code> to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. <code>none</code> indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (').
<verbose>	The level of verbosity as one of: <ul style="list-style-type: none"> 1 - print header of packets 2 - print header and data from IP of packets 3 - print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run forever until you stop it with <code><CTRL C></code> .

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the `port1` interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as `ack`), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

Generate specific packets to test the network

If some packets are being delivered as expected while others are not, or after you believe you have fixed the problem, it is a good idea to generate specific traffic to test your network.

For example if you discover through log messages and packet sniffing that Create PDP Context Request messages are not being delivered between two SGSNs, you can generate those specific messages on your network to confirm they are the problem, and later that you have solved the problem and they are now being delivered as expected.

This step requires a third party traffic generation tool, either hardware or software. This is not supported by Fortinet.

Chapter 6 - Firewall

This guide contains a number of different topics that, at its simplest, can be grouped into fundamental firewall topics such as policies, objects and network defense and topics that have to do with the optimization of the firewall such as WAN optimization, proxies and caching.

Fundamentals

"[Firewall concepts](#)" on [page 522](#) explains the ideas behind the components, techniques and processes that are involved in setting up and running a firewall in general and the FortiGate firewall in particular. The premise here is that regardless of how experienced someone is with firewalls as they go through the process of configuring a firewall that is new to them they are likely to come across a term or setting that they may not be familiar with even if it is only in the context of the setting they are working in at the moment. FortiGate firewalls are quite comprehensive and can be very granular in the functions that they perform, so it makes sense to have a consistent frame of reference for the ideas that we will be working with.

Some examples of the concepts that will be addressed here are:

- "What is a Firewall?"
- "NAT"
- "IPv6"

"Firewall objects" describes the following firewall objects:

- Addressing
- Services
- Firewall Policies

"[Network defense](#)" on [page 665](#) describes various methods of defending your Network using the abilities of the FortiGate Firewall.

"[Object configuration](#)" on [page 705](#) is similar to a cookbook in that it will refer to a number of common tasks that you will likely perform to get the full functionality out of your FortiGate firewall. Because of the way that firewalls are designed, performing many of the tasks requires that firewall components be set up in a number of different sections of the interface and be configured to work together to achieve the desired result. This section will bring those components all together as a straight forward series of instructions.

FortiGate firewall components

The FortiGate firewall is made up of a number of different components that are used to build an impressive list of features that have flexibility of scope and granularity of control that provide protection that is beyond that provided by the basic firewalls of the past.

Some of the components that FortiOS uses to build features are:

- Interfaces
- VLANs
- Soft Switches

- Zones
- Predefined Addresses
- IP address based
- FQDN based
- Geography based
- Access Schedules
- Authentication
- Local User based
- Authentication Server based (Active Directory, Radius, LDAP)
- Device Based
- Configureable Services
- IPv4 and IPv6 protocol support

The features of FortiOS include but are not limited to:

- Security profiles, sometimes referred to as Unified Threat Management (UTM) or Next Generation Firewall (NGFW)
- Predefined firewall addresses (this includes IPv4 and IPv6, IP pools, . wildcard addresses and netmasks, and geography-based addresses)
- Monitoring traffic
- Traffic shaping and per-IP traffic shaping (advanced)
- Firewall schedules
- Services (such as AOL, DHCP and FTP)
- Logging traffic
- Quality of Service (QoS)
- Identity-based policies
- Endpoint security

Firewall optimization

There are a few different methodologies of optimization and most of these methodologies has been divided into:

- Concepts section - This will have the basic ideas behind the how and why of the topic. Because the number of topics is larger, the ideas are not as pervasive and the content is not so extensive as in the Fundamental section, some of the topics will include instructions on the configuration of that individual topic in order to keep the information for granular topics together.
- Configuration section- Just like the Configuration section of the Fundamentals, this will be a cookbook style of documentation showing how to configure something that achieves a specific functionality from the FortiGate.

The optimization topics include:

- [Secure web gateway, WAN optimization, web caching and WCCP](#)
- [Example topologies relevant to WAN optimization](#)
- [Inside FortiOS: WAN optimization](#)
- [WAN optimization concepts](#)
- [WAN optimization configuration](#)

- Peers and authentication groups
- Web cache concepts
- Web cache configuration
- WCCP concepts
- WCCP configuration
- Web proxy concepts
- Web proxy configuration
- Explicit proxy concepts
- Explicit proxy configuration
- Transparent proxy concepts
- Transparent proxy configuration
- FTP proxy concepts
- FTP proxy configuration
- Diagnose commands for WAN optimization

How does a FortiGate protect your network?

The FortiGate firewall protects your network by taking the various components and using them together to build a kind of wall or access control point so that anyone that is not supposed to be on your network is prevented from accessing your network in anyway other than those approved by you. It also protects your network from itself by keeping things that shouldn't happen from happening and optimizing the flow of traffic so that the network is protected from traffic congestion that would otherwise impede traffic flow.

Most people have at one time or another played with the children's toy system that is made up of interlocking blocks. The blocks come in different shapes and sizes so that you can build structures to suit your needs and in your way. The components of the FortiGate firewall are similar. You are not forced to use all of the blocks all of the time. You mix and match them to get the results that you are looking for. You can build a very basic structure that's only function is to direct traffic in and out to the correct subnets or you can build a fortress that only allows specific traffic to specific hosts from specific hosts at specific times of day and that is only if they provide the credentials that have been pre-approved and all of the traffic is encrypted so that even when the traffic is out on the Internet it is private from the world. Just like the interlocking blocks, what you build is up to you, but chances are if you put them together the right way there isn't much that can't be built.

Here is one example of how the components could be put together to support the requirements of a network infrastructure design.

- Off the Internal interface you could have separate VLANs. One for each for the departments of Sales, Marketing and Engineering so that the traffic from the users on one VLAN does not intrude upon the hosts of the other VLANs and the department are isolated from one another for security reasons.
- To ease in the administration each of the VLAN sub-interfaces is made a member of a zone so that security policies that apply to all of the hosts on all of the VLANs can be applied to all of them at once.
- Using the addresses component each of the IP address ranges could be assigned a user friendly name so that they could be referred to individually and then for policies that would refer to them all as a whole the individual ranges to be made members of an address group.
- Firewall schedules could be created to address the differing needs of each of the groups so that Sales and Marketing could be allowed access to the Internet during regular business hours and the Engineering department could be allowed access during the lunch break.

- By setting up the outgoing policies to use FortiGuard Web-filtering the employees could be prevented from visiting inappropriate sites and thus enforcing the policies of the HR department.
- A couple of virtual IP addresses with port forwarding could be configured to allow users on the Internet to access a web server on the DMZ subnet using the company's only Public IP address without affecting the traffic that goes to the company's mail server that is hosted on a complete different computer.
- Even though the Web server on the same DMZ has an FTP service to allow for the uploading of web pages to the web server from the Marketing and Engineer teams, by placing a DENY policy on any FTP traffic from the Internet malicious users are prevented from abusing the FTP service.
- By monitoring the traffic as it goes through the policies you can verify that the policies are in working order.
- By using a combination of ALLOW and DENY policies and placing them in the correct order you could arrange for an outside contractor to be allowed to update the web site as well

These set of configurations is not extensive but it does give an idea of how different components can be mixed and matched to build a configuration that meets an organization's needs but at the same time protect it from security risks.

What's new for Firewall in 6.0.1

Firewall concepts

There are a number of foundational concepts that are necessary to have a grasp of before delving into the details of how the FortiGate firewall works. Some of these concepts are consistent throughout the firewall industry and some of them are specific to more advanced firewalls such as the FortiGate. Having a solid grasp of these ideas and terms can give you a better idea of what your FortiGate firewall is capable of and how it will be able to fit within your networks architecture.

This chapter describes the following firewall concepts:

- [What is a firewall?](#)
- [FortiGate modes](#)
- [How packets are handled by FortiOS](#)
- [Interfaces and zones](#)
- [Access control lists](#)
- [IPv6](#)
- [NAT](#)

- ["Traffic logging" on page 611](#)

What is a firewall?

The term firewall originally referred to a wall intended to confine a fire or potential fire within a building. Later uses refer to similar structures, such as the metal sheet separating the engine compartment of a vehicle or aircraft from the passenger compartment.

A firewall can either be software-based or hardware-based and is used to help keep a network secure. Its primary objective is to control the incoming and outgoing network traffic by analyzing the data packets and determining whether it should be allowed through or not, based on a predetermined rule set. A network's firewall builds a bridge between an internal network that is assumed to be secure and trusted, and another network, usually an external (inter)network, such as the Internet, that is not assumed to be secure and trusted.

Network layer or packet filter firewalls

Stateless firewalls

Stateless firewalls are the oldest form of these firewalls. They are faster and simple in design requiring less memory because they process each packet individually and don't require the resources necessary to hold onto packets like stateful firewalls. Stateful firewalls inspect each packet individually and check to see if it matches a predetermined set of rules. According to the matching rule the packet is either be allowed, dropped or rejected. In the case of a rejection an error message is sent to the source of the traffic. Each packet is inspected in isolation and information is only gathered from the packet itself. Simply put, if the packets were not specifically allowed according to the list of rules held by the firewall they were not getting through.

Stateful Firewalls

Stateful firewalls retain packets in memory so that they can maintain context about active sessions and make judgments about the state of an incoming packet's connection. This enables Stateful firewalls to determine if a packet is the start of a new connection, a part of an existing connection, or not part of any connection. If a packet is part of an existing connection based on comparison with the firewall's state table, it will be allowed to pass without further processing. If a packet does not match an existing connection, it will be evaluated according to the rules set for new connections. Predetermined rules are used in the same way as a stateless firewall but they can now work with the additional criteria of the state of the connection to the firewall.

Best Practices Tip for improving performance:

Blocking the packets in a denied session can take more cpu processing resources than passing the traffic through. By putting denied sessions in the session table, they can be kept track of in the same way that allowed session are so that the FortiGate unit does not have to redetermine whether or not to deny all of the packets of a session individually. If the session is denied all packets of that session are also denied.

In order to configure this you will need to use 2 CLI commands

```
config system setting
    set ses-denied-traffic enable
    set block-session-timer <integer 1 - 300> (this determines in
seconds how long, in seconds, the session is kept in the table)
end
```

Application layer firewalls

Application layer filtering is yet another approach and as the name implies it works primarily on the Application Layer of the OSI Model.

Application Layer Firewalls actually, for lack of a better term, understand certain applications and protocols. Examples would be FTP, DNS and HTTP. This form of filtration is able to check to see if the packets are actually behaving incorrectly or if the packets have been incorrectly formatted for the protocol that is indicated. This process also allows for the use of deep packet inspection and the sharing of functionality with Intrusion Prevention Systems (IPS).

Application-layer firewalls work on the application level of the TCP/IP stack (i.e., all browser traffic, or all telnet or ftp traffic), and may intercept all packets traveling to or from an application. They block other packets (usually

dropping them without acknowledgment to the sender). Application firewalls work much like a packet filter but application filters apply filtering rules (allow/block) on a per process basis instead of filtering connections on a per port basis.

On inspecting all packets for improper content, firewalls can restrict or prevent outright the spread of networked computer worms and trojans. The additional inspection criteria can add extra latency to the forwarding of packets to their destination.

Proxy servers

A proxy server is an appliance or application that acts as an intermediary for communicating between computers. A computer has a request for information. The packets are sent to the designated resource but before they can get there they are blocked by the proxy server saying that it will take the request and pass it on. The Proxy Server processes the request and if it is valid it passes onto the designated computer. The designated computer gets the packet and processes the request, sending the answer back to the proxy server. The proxy server sends the information back to the originating computer. It's all a little like a situation with two people who refuse to talk directly with each other using someone else to take messages back and forth.

From a security stand point a Proxy Server can serve a few purposes:

- Protects the anonymity of the originating computer
- The two computers never deal directly with each other
- Packets that are not configured to be forwarded are dropped before reaching the destination computer.
- If malicious code is sent it will affect the Proxy server with out affecting the originating or sending computer.

Proxies can perform a number of roles including:

- Content Filtering
- Caching
- DNS proxy
- Bypassing Filters and Censorship
- Logging and eavesdropping
- Gateways to private networks
- Accessing service anonymously

UTM/ NGFW

Unified Threat Management and Next Generation Firewall are terms originally coined by market research firms and refer to the concept of a comprehensive security solution provided in a single package. It is basically combining of what used to be accomplished by a number of different security technologies all under a single umbrella or in this case, a single device. On the FortiGate firewall this is achieved by the use of Security Profiles and optimized hardware.

In effect it is going from a previous style of firewall that included among its features:

- Gateway Network Firewall
- Routing
- VPN

To a more complete system that includes:

- Gateway Network Firewall
- Routing

- VPN
- Traffic Optimization
- Proxy Services
- Content Filtering
- Application Control
- Intrusion Protection
- Denial of Service Attack Protection
- Anti-virus
- Anti-spam
- Data Leak Prevention
- Endpoint Control of Security Applications
- Load Balancing
- WiFi Access Management
- Authentication Integration into Gateway Security
- Logging
- Reporting

Advantages of using security profiles

- Avoidance of multiple installations.
- Hardware requirements are fewer.
- Fewer hardware maintenance requirements.
- Less space required.
- Compatibility - multiple installations of products increase the probability of incompatibility between systems.
- Easier support and management.
- There is only one product to learn therefore a reduced requirement of technical knowledge.
- Only a single vendor so there are fewer support contracts and Service Level Agreements.
- Easier to incorporate into existing security architecture.
- Plug and play architecture.
- Web based GUI for administration.

FortiGate modes

The FortiGate unit has a choice of modes that it can be used in, either NAT/Route mode or transparent mode. The FortiGate unit is able to operate as a firewall in both modes, but some of its features are limited in transparent mode. It is always best to choose which mode you are going to be using at the beginning of the set up. Once you start configuring the device, if you want to change the mode you are going to lose all configuration settings in the change process.

NAT/Route mode

NAT/Route mode is the most commonly used mode by a significant margin and is thus the default setting on the device. As the name implies the function of NAT is commonly used in this mode and is easily configured but there is no requirement to use NAT. The FortiGate unit performs network address translation before IP packets are sent to the destination network.

These are some of the characteristics of NAT/Route mode:

- Typically used when the FortiGate unit is a gateway between private and public networks.
- Can act as a router between multiple networks within a network infrastructure.
- When used, the FortiGate unit is visible to the networks that it is connected to.
- Each logical interface is on a distinct subnet.
- Each Interface needs to be assigned a valid IP address for the subnet that it is connected to it.

Transparent mode

Transparent mode is so named because the device is effectively transparent in that it does not appear on the network in the way that other network devices show as nodes in the path of network traffic. Transparent mode is typically used to apply the FortiOS features such as Security Profiles etc. on a private network where the FortiGate unit will be behind an existing firewall or router.

These are some of the characteristics of transparent mode:

- The FortiGate unit is invisible to the network.
- All of its interfaces are on the same subnet and share the same IP address.
- The FortiGate unit uses a Management IP address for the purposes of Administration.
- Still able to use NAT to a degree, but the configuration is less straightforward

In transparent mode, you can also perform NAT by creating a security policy or policies that translates the source addresses of packets passing through the FortiGate unit as well as virtual IP addresses and/or IP pools.

How packets are handled by FortiOS

To give you idea of what happens to a packet as it makes its way through the FortiGate unit here is a brief overview. This particular trip of the packet is starting on the Internet side of the FortiGate firewall and ends with the packet exiting to the Internal network. An outbound trip would be similar. At any point in the path if the packet is going through what would be considered a filtering process and if fails the filter check the packet is dropped and does not continue any further down the path.

This information is covered in more detail in other in the Troubleshooting chapter of the FortiOS Handbook in the Life of a Packet section.

The incoming packet arrives at the external interface. This process of entering the device is referred to as **ingress**.

Step #1 - Ingress

1. Denial of Service Sensor
2. IP integrity header checking
3. IPsec connection check
4. Destination NAT
5. Routing

Step #2 - Stateful inspection engine

1. Session Helpers
2. Management Traffic
3. SSL VPN
4. User Authentication

5. Traffic Shaping
6. Session Tracking
7. Policy lookup

Step #3 - Security profiles scanning process

1. Flow-based Inspection Engine
2. IPS
3. Application Control
4. Data Leak Prevention
5. Email Filter
6. Web Filter
7. Anti-virus
8. Proxy-based Inspection Engine
9. VoIP Inspection
10. Data Leak Prevention
11. Email Filter
12. Web Filter
13. Anti-virus
14. ICAP

Step #4 - Egress

1. IPsec
2. Source NAT
3. Routing

Interfaces and zones

A Firewall is a gateway device that may be the nexus point for more than 2 networks. The interface that the traffic is coming in on and should be going out on is a fundamental concern for the purposes of routing as well as security. Routing, policies and addresses are all associated with interfaces. The interface is essentially the connection point of a subnet to the FortiGate unit and once connected can be connected to other subnets.

The following types of interfaces are found on a FortiGate:

- Interface , this can refer to a physical or virtual interface
- Zone
- Virtual Wired Pair

Interfaces

Physical interfaces or not the only ones that need to be considered. There are also virtual interfaces that can be applied to security policies. VLANs are one such virtual interface. Interfaces if certain VPN tunnels are another.

Policies are the foundation of the traffic control in a firewall and the Interfaces and addressing is the foundation that policies are based upon. Using the identity of the interface that the traffic connects to the FortiGate unit tells the firewall the initial direction of the traffic. The direction of the traffic is one of the determining factors in

deciding how the traffic should be dealt with. You can tell that interfaces are a fundamental part of the policies because, by default, this is the criteria that the policies are sorted by.

Zones

Zones are a mechanism that was created to help in the administration of the firewalls. If you have a FortiGate unit with a large number of ports and a large number of nodes in your network the chances are high that there is going to be some duplication of policies. Zones provide the option of logically grouping multiple virtual and physical FortiGate firewall interfaces. The zones can then be used to apply security policies to control the incoming and outgoing traffic on those interfaces. This helps to keep the administration of the firewall simple and maintain consistency.

For example you may have several floors of people and each of the port interfaces could go to a separate floor where it connects to a switch controlling a different subnet. The people may be on different subnets but in terms of security they have the same requirements. If there were 4 floors and 4 interfaces a separate policy would have to be written for each floor to be allowed out on to the Internet off the WAN1 interface. This is not too bad if that is all that is being done, but now start adding the use of more complicated policy scenarios with Security Profiles, then throw in a number of Identity based issues and then add the complication that people in that organization tend to move around in that building between floors with their notebook computers.

Each time a policy is created for each of those floors there is a chance of an inconsistency cropping up. Rather than make up an additional duplicate set of policies for each floor, a zone can be created that combines multiple interfaces. And then a single policy can be created that uses that zone as one side of the traffic connection.

You cannot add physical interfaces associated with VLANs to zones.

Virtual wire pair

The simplified explanation is that two interfaces are set up so that whatever traffic goes through one of the pair is replicated on the other. They are most commonly used when scanning is needed on an interface without interfering with the traffic. On interface "A", everything goes through unaffected. The replicated traffic on interface "B" is sent to an analyzer of some kind and the traffic can be thoroughly scanned without worry of impacting performance.

When two physical interfaces are setup as a Virtual Wire Pair, they will have no IP addressing and are treated similar to a transparent mode VDOM. All packets accepted by one of the interfaces in a virtual wire pair can only exit the FortiGate through the other interface in the virtual wire pair and only if allowed by a virtual wire pair firewall policy. Packets arriving on other interfaces cannot be routed to the interfaces in a virtual wire pair. A FortiGate can have multiple virtual wire pairs.

You cannot add VLANs to virtual wire pairs. However, you can enable wildcard VLANs for a virtual wire pair. This means that all VLAN-tagged traffic can pass through the virtual wire pair if allowed by virtual wire pair firewall policies.

Access control lists

Access control lists (ACLs) in the FortiOS firmware could be considered a granular or more specifically targeted blacklist. These ACLs drop IPv4 or IPv6 packets at the physical network interface before the packets are analyzed by the CPU. On a busy appliance this can really help the performance.

The ACL feature is available on FortiGates with NP6-accelerated interfaces. ACL checking is one of the first things that happens to the packet and checking is done by the NP6 processor. The result is very efficient protection that does not use CPU or memory resources.

Incoming interfaces

The configuration of the Access Control List allow you to specify which in interface the ACL will be applied to. There is a hardware limitation that needs to be taken into account. The ACL is a Layer 2 function and is offloaded to the ISF hardware, therefore no CPU resources are used in the processing of the ACL. It is handled by the inside switch chip which can do hardware acceleration, increasing the performance of the FortiGate. The drawback is that the ACL function is only supported on switch fabric driven interfaces. It also cannot be applied to hardware switch interfaces or their members. Ports such as WAN1 or WAN2 that are found on some models that use network cards that connect to the CPU through a PCIe bus will not support ACL.

Addresses

Because the address portion of an entry is based on a FortiGate address object, it can be any of the address types used by the FortiGate, including address ranges. There is further granularity by specifying both the source and destination addresses. The traffic is blocked not on an either or basis of these addresses but the combination of the two, so that they both have to be correct for the traffic to be denied. Of course, If you want to block all of the traffic from a specific address all you have to do is make the destination address "all".

Because the blocking takes place at the interface based on the information in the packet header and before any processing such as NAT can take place, a slightly different approach may be required. For instance, if you are trying to protect a VIP which has an external address of x.x.x.x and is forwarded to an internal address of y.y.y.y, the destination address that should be used is x.x.x.x, because that is the address that will be in the packet's header when it hits the incoming interface.

Services

Further granulation of the filter by which the traffic will be denied is done by specifying which service the traffic will use.

Firewall policies

The firewall policy is the axis around which most of the other features of the FortiGate firewall revolve. A large portion of the settings in the firewall at some point will end up relating to or being associated with the firewall policies and the traffic that they govern. Any traffic going through a FortiGate unit has to be associated with a policy. These policies are essentially discrete compartmentalized sets of instructions that control the traffic flow going through the firewall. These instructions control where the traffic goes, how it's processed, if it's processed and even whether or not it's allowed to pass through the FortiGate.

When the firewall receives a connection packet, it analyzes the packet's source address, destination address, and service (by port number). It also registers the incoming interface, the outgoing interface it will need to use and the time of day. Using this information the FortiGate firewall attempts to locate a security policy that matches the packet. If it finds a policy that matches the parameters it then looks at the action for that policy. If it is **ACCEPT** the traffic is allowed to proceed to the next step. If the Action is **DENY** or a match cannot be found the traffic is not allowed to proceed.

The 2 basic actions at the initial connection are either **ACCEPT** or **DENY**:

- If the **Action** is **ACCEPT**, the policy action permits communication sessions. There may be other packet processing instructions, such as requiring authentication to use the policy or restrictions on the source and

destination of the traffic.

- If the **Action** is **DENY**, the policy action blocks communication sessions, and you can optionally log the denied traffic. If no security policy matches the traffic, the packets are dropped. A **DENY** security policy is needed when it is required to log the denied traffic, also called “violation traffic”.

There are two other Actions that can be associated with the policy:

- **LEARN** - This is a specialized variation on the **ACCEPT** action. That is set up to allow traffic but to keep traffic logs so that the administrator can go through them to learn what kind of traffic has to be dealt with.
- **IPsec** - This is an **ACCEPT** action that is specifically for IPsec VPNs.

There can also be a number of instructions associated with a FortiGate firewall in addition to the **ACCEPT** or **DENY** actions, some of which are optional. Instructions on how to process the traffic can also include such things as:

- Logging Traffic
- Authentication
- Network Address Translation or Port Address Translation
- Use Virtual IPs or IP Pools
- Caching
- Whether the source of the traffic is based on address, user, device or a combination
- Whether to treat as regular traffic or IPsec traffic
- What certificates to use
- Security profiles to apply
- Proxy Options
- Traffic Shaping

Firewall policy parameters

As mentioned before, for traffic to flow through the FortiGate firewall there must be a policy that matches its parameters:

Incoming interface(s)

This is the interface or interfaces that the traffic is first connection to the FortiGate unit by. The exception being traffic that the FortiGate generates itself. This is not limited to the physical Ethernet ports found on the device. The incoming interface can also be a logical or virtual interface such as a VPN tunnel, a Virtual WAN link or a wireless interface.

Outgoing interface(s)

After the firewall has processed the traffic it needs to leave a port to get to its destination and this will be the interface or interfaces that the traffic leaves by. This interface, like the **Incoming Interface** is not limited to only physical interfaces.

Source address(es)

The addresses that a policy can receive traffic from can be wide open or tightly controlled. For a public web server that the world at large should be able to access, the best choice will be “all”. If the destination is a private web server that only the branch offices of a company should be able to access or a list of internal computers that are

the only ones allowed to access an external resource then a group of preconfigured addresses is the better strategy.

Additional parameters under the Source Address, though they are not mandatory are:

- **Source User(s)**

This parameter is based on a user identity that can be from a number of authentication authorities. It will be an account or group that has been set up in advance that can be selected from the drop down menu. The exception to this is the feature that allows the importing of LDAP Users. When the feature is used, a small wizard window will appear to guide the user through the setup. The caveat is that the LDAP server object in the **User and Device > Authentication > LDAP Servers** section has to be already configured to allow the use of this import feature.

- **Source Device Type**

This parameter is for narrowing down the traffic sending devices to those that the FortiGate is familiar with. Again the contents of this parameter need to be a preconfigured object and these are defined at **User and Device > Custom Devices & Groups**. This parameter can limit the devices that can connect to this policy to those specific MAC addresses that are already known by the FortiGate and are approved for the policy.

Destination address(es)

In the same way that the source address may need to be limited, the destination address can be used as a traffic filter. When the traffic is destined for internal resources the specific address of the resource can be defined to better protect the other resources on the network. One of the specialized destination address options is to use a Virtual IP address. The destination address doesn't need to be internal you can define policies that are only for connecting to specific addresses on the Internet.

Internet service(s)

In this context, and Internet service is a combination of one or more addresses and one or more services associated with a service found on the Internet such as an update service for software.

Schedule

The time frame that is applied to the policy. This can be something as simple as a time range that the sessions are allowed to start such as between 8:00 am and 5:00 pm. Something more complex like business hours that include a break for lunch and time of the session's initiation may need a schedule group because it will require multiple time ranges to make up the schedule.

Service

The service or service chosen here represent the TCP/IP suite port numbers that will most commonly be used to transport the named protocols or group of protocols. This will be a little different than Application Control which looks more closely at the packets to determine the actual protocol used to create them.

Without all six (possibly 8) of these things matching, the traffic will be declined. Each traffic flow requires a policy and the direction is important as well. Just because packets can go from point A to point B on port X does not mean that the traffic can flow from point B to point A on port X. A policy must be configured for each direction.

When designing a policy there is often reference to the traffic flow, but most communication is a two way connection so trying to determine the direction of the flow can be somewhat confusing. If traffic is HTTP web traffic the user sends a request to the web site, but most of the traffic flow will be coming from the web site to the user. Is the traffic flow considered to be from the user to the web site, the web site to the user or in both directions? For the purposes of determining the direction for a policy the important factor is the direction of the

initiating communication. The user is sending a request to the web site so this is the initial communication and the web site is just responding to it so the traffic will be from the users network to the Internet.

A case where either side can initiate the communication like between two internal interfaces on the FortiGate unit would be a more likely situation to require a policy for each direction.

Application groups for NGFW policies

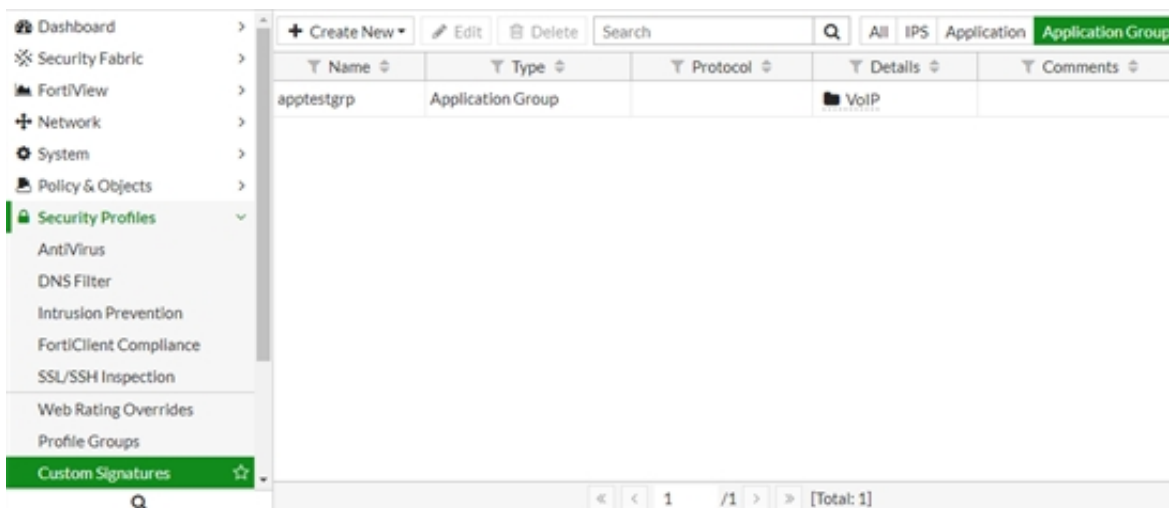

In addition to parameters like schedule and service, NGFW policies can filter by application or application category.

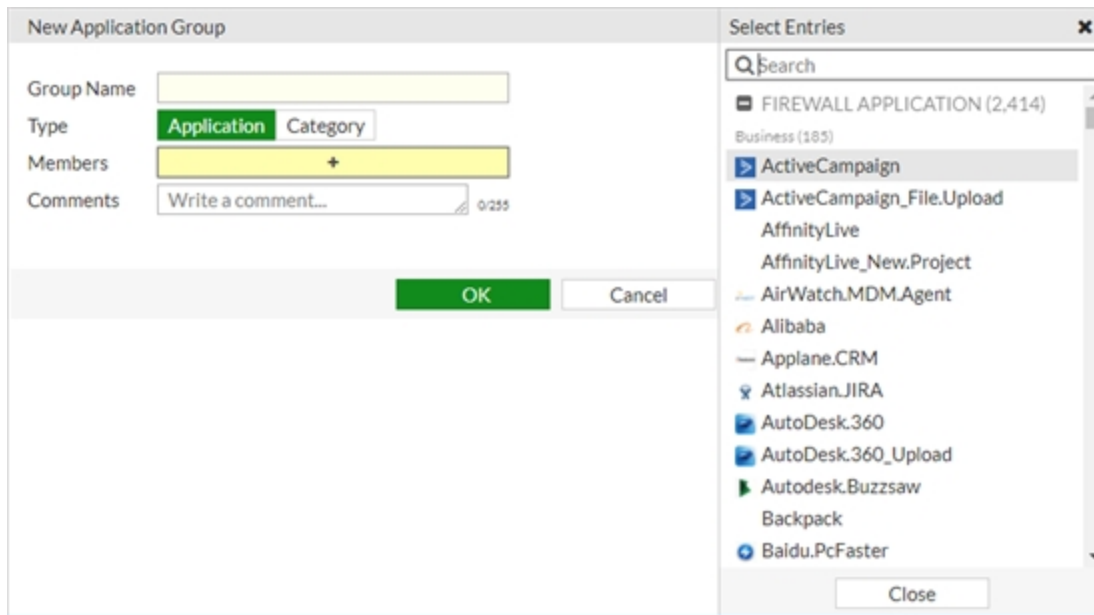

The use of this feature is dependent upon the VDOM having the following **System Operation Settings**:

- **Inspection Mode: Flow-based**
- **NGFW Mode: Policy-based**

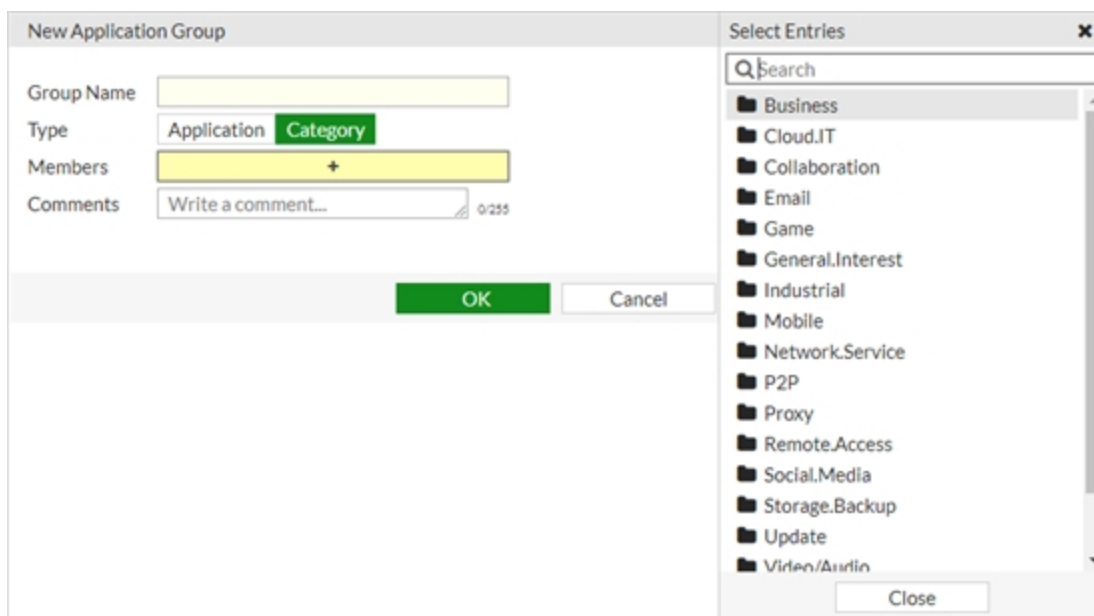

To use the feature first create an application group in **Security Profiles > Custom Signatures**.

From the editing page for the **New Application Group**, choose a group type of **Application** and select individual applications for membership in the group.

Alternatively, select **Category** and add one or more application categories as group members.

Whichever type of **Application Group** you choose, the available **Members** will be displayed in the selection pane that slides out from the right of the window.

Once the **Application Group** is created, you can apply it to a policy in the **Application** field, by clicking on the **+** in the field and selecting members from the options under the **Group** tab at the top of the pane that slides out from the right of the window.

CLI

To create or edit an application group:

```
config application group
  edit <group_name>
    set comments
    set type {application | category}
    set application <Application ID number>
    set category <category ID number>
  end
```

To add an application group to a policy:

```
config firewall policy
  edit 1
    set app-group "test" "test1"
  end
```

Application ID number

In the CLI, you add applications to a group by using the application ID number. To see the list of application ID numbers, run the following command when `type` is set to `application`:

```
set application ? <enter>
```

The start of the list looks like:

```
set application
ID          Select Application ID
38614       1kxun
29025       1undl.Mail
17534       2ch
17535       2ch_Post
16284       3PC
16616       4shared
```

```

35760      4shared_File.Download
34742      4shared_File.Upload
44606      5ch
44607      5ch_Post
38923      8tracks
17045      9PFS
16554      126.Mail
23345      360.Safeguard.Update
35963      360.Yunpan
35967      360.Yunpan_File.Download
35966      360.Yunpan_File.Upload
42324      360.Yunpan_Login
16413      A.N
31529      ABC
...

```

Only the first 20 have been listed here.

Category ID number

The ID numbers for the categories in the CLI are found in the same manner as the applications. When the `type` is set to `category`, run the command:

```
set category ? <enter>
```

This list is shorter.

```

set category
ID          Select Category ID
2           P2P
3           VoIP
5           Video/Audio
6           Proxy
7           Remote.Access
8           Game
12          General.Interest
15          Network.Service
17          Update
21          Email
22          Storage.Backup
23          Social.Media

```

25	Web.Client
26	Industrial
28	Collaboration
29	Business
30	Cloud.IT
31	Mobile

What is not expressly allowed is denied

One of the fundamental ideas that can be found in just about any firewall is the rule than anything that is not expressly allowed is by default denied. This is the foundation for any strategy of protecting your network. Right out of the box, once you have your FortiGate device connected into your network and hooked up with your ISP, your network is protected. Nothing is getting out or in so it is not very convenient, but you don't have to worry that between the time you hooked it up and the point that you got all of the policies in place that someone could have gotten in and done something to your resources. The reason that this needs to be kept in mind when designing policies is because you cannot assume that any traffic will be allowed just because it makes sense to do so. If you want any kind of traffic to make it past the FortiGate firewall you need to create a policy that will allow that traffic. To maintain the protection of the network should also make sure that the any policy you create allows only the traffic you intend to go only to where you specifically want it to go and when you want it to go there.

Example

You have a web server on your network that is meant to provide a collaborative work environment web site for your employees and a partner company for a project over the course of the next 3 months.

It is theoretically possible to allow connections into your network to any device on that network for any service and at any time. The problem with this is that we might not want just anybody looking at those resources. Sadly, no matter how much it is wished otherwise, not everybody on the Internet can be trusted. Which means we now have to be very specific in our instructions as to what traffic to allow into the network. Each step that we take towards being more specific as to what we allow means that there is that much more that is not allowed and the level of protection of a resources is directly proportional to the amount of traffic that is not allowed. If somebody can't get at it they can't damage or steal it.

Limiting where the traffic is allowed to go to means that other computers on your network besides the web-server are protected.

- Limiting where the traffic is allowed to come from means that, if feasible, you can limit the systems that can access the web server to just employees or the partner company computers.
- Limiting the services to just web traffic means that a malicious person, even if they were connection from a computer at the partner organization could only use the features of web traffic to do anything malicious.
- Limiting the policy to the time span of the project would mean that even if the IT department forgot to remove the policy after the end of the project than no computer from the other company could be used to do anything malicious through the policy that allowed the traffic.

This is just a very basic example but it shows the underlying principles of how the idea that anything not expressly allowed is by default denied can be used to effectively protect your network.

Policy order

Another important factor in how firewall policies work is the concept of precedence of order or if you prefer a more recognizable term, “first come, first served”.

It is highly likely that even after only a relatively small number of policies have been created that there will be some that overlap or are subsets of the parameters that the policies use to determine which policy should be matched against the incoming traffic. When this happens there has to be a method to determine which policy should be applied to the packet. The method which is used by most firewalls is based on the order of the sequence of the policies.

If all of the policies were placed in a sequential list the process to match up the packet would start at the top of the list and work its way down. It would compare information about the packet, specifically these points of information:

1. The interface the packet connected to the FortiGate firewall
2. The source of the packet. This can include variations of the address, user credentials or device
3. The destination of the packet. This can include address or Internet service
4. The interface the packet would need to use to get to the destination address based on the routing table
5. The service or port the packet is destined for
6. The time that the packet connected to the FortiGate

As soon as the a policy is reached that matches all of the applicable parameters, the instructions of that policy are applied and the search for any other matching policies is stopped. All subsequent policies are disregarded. Only 1 policy is applied to the packet.

If there is no matching policy among the policies that have been configured for traffic the packet finally drops down to what is always the last policy. It is an implicit policy. One of a few that are referred to by the term “policy0”. This policy denies everything.

The implicit policy is made up of the following settings:

- Incoming Interface: any
- Source Address: any
- Outgoing Interface: any
- Destination Address: any
- Action: DENY

The only setting that is editable in the implicit policy is the logging of violation traffic.

A logical best practice that comes from the knowledge of how this process works is to make sure that the more specific or specialized a policy is, the closer to the beginning of the sequence it should be. The more general a policy is the higher the likelihood that it could include in its range of parameters a more specifically targeted policy. The more specific a policy is, the higher the probability that there is a requirement for treating that traffic in a specific way.

Example

For security reasons there is no FTP traffic allowed out of a specific subnet so there is a policy that states that any traffic coming from that subnet is denied if the service is FTP, so the following policy was created:

Policy #1

Source Interface	Internal1
Source Address	192.168.1.0/24
Source User(s)	<left at default setting>
Source Device Type	<left at default setting>
Outgoing Interface	WAN1
Destination Address	0.0.0.0/0.0.0.0
Service	FTP
Schedule	always
Action	deny

Now as these things usually go it turns out that there has to be an exception to the rule. There is one very secure computer on the subnet that is allowed to use FTP and once the content has been checked it can then be distributed to the other computer on the subnet. So a second firewall policy is created.

Policy #2

Source Interface	Internal1
Source Address	192.168.1.38/32
Source User(s)	<left at default setting>
Source Device Type	<left at default setting>
Outgoing Interface	WAN1
Destination Address	0.0.0.0/0.0.0.0
Service	FTP
Schedule	always
Action	Allow

By default, a policy that has just been created will be placed last in the sequence so that it is less likely to interfere with existing policies before it can be moved to its intended position. If you look at Policy #2 you will notice that it is essentially the same as Policy #1 exempt for the Source Address and the Action. You will also notice that the Source Address of the Policy #2 is a subset of the Source address in policy #1. This means that if nothing further is done, Policy #2 will never see any traffic because the traffic will always be matched by Policy #1 and processed before it has a chance to reach the second policy in the sequence. For both policies to work as intended Policy #2 needs to be moved to before Policy #1 in the sequence.

Policy identification

There are two ways to identify a policy. The most obvious is the policy name and this is easily read by humans, but with a little effort it is possible to have a policy without a name, therefore every policy has an ID number.

When looking at the policy listing it can appear as if the policies are identified by the sequence number in the far left column. The problem is that this number changes as the position of the policy in the sequence changes. The column that correctly identifies the policy, and the value sticks with the policy is the "ID" column. This column is not shown by default in the listing but can be added to the displayed columns by right clicking on the column heading bar and selecting it from the list of possible columns.

When looking in the configuration file the sequence is based upon the order of the policies as they are in the file just as they are in the list in the GUI. However, if you need to edit the policy in the CLI you must use the ID number.

UUID support

Universally Unique Identifier (UUID) attributes have been added to policies to improve functionality when working with FortiManager or FortiAnalyzer units. If required, the UUID can be set manually through the CLI.

CLI Syntax:

```
config firewall {policy/policy6/policy46/policy64}
  edit 1
    set uuid <example uuid: 8289ef80-f879-51e2-20dd-fa62c5c51f44>
  next
end
```

NTurbo support CAPWAP traffic

NTurbo is used for IPSec+IPS case. The IPSec SA info is passed to NTurbo as part of VTAG for control packet and will be used for the xmit.

If the packets need to go through IPSec interface, the traffic will be always offloaded to NTurbo. But for the case that SA has not been installed to NP6 because of hardware limitation or SA offload disable, the packets will be sent out through raw socket by IPS instead of NTurbo, since the software encryption is needed in this case.

CLI :

Previously, NTurbo could only be enabled or disabled globally. The setting of np-acceleration has been added to the firewall policy context instead of just the global context.

CLI command in the firewall policy to enable/disable NTurbo acceleration.

```
config firewall policy
  edit 1
    set np-acceleration [enable|disable]
```

end

When IPS is enabled for VPN IPsec traffic, the data can be accelerated by NTurbo.

Learning mode for policies

The learning mode feature is a quick and easy method for setting a policy to allow everything but to log it all so that it can later be used to determine what restrictions and protections should be applied. The objective is to monitor the traffic not act upon it while in Learning mode.

Once the **Learn** action is enabled, functions produce hard coded profiles that will be enabled on the policy. The following profiles are set up:

- AntiVirus (av-profile)
- Web Filter (webfilter-profile)
- Anti Spam(spamfilter-profile)
- Data Leak Prevention (dlp-sensor)
- Intrusion Protection (ips-sensor)
- Application Control (application-list)
- Proxy Options (profile-protocol-options)

- These UTM profiles are all using Flow mode
 - SSL inspection is always disabled for the Learn option
 - These profiles are static and cannot be edited.
-

Profiles that are not being used are:

- DNS Filter (Does not have a Flow mode)
- Web Application Firewall (Does not have a Flow mode)
- CASI (Almost all signatures in CASI require SSL deep inspection. Without SSL inspection, turning on CASI serves little purpose)

The ability to allow policies to be set to a learning mode is enabled on a per VDOM basis.

```
config system settings
  set gui-policy-learning [enable | disable]
end
```

Once the feature is enabled on the VDOM, Learn is an available **Action** option when editing a policy.

Because this feature requires a minimum level of logging capabilities, it is only available on FortiGates with hard drives. Smaller models may not be able to use this feature.

Once the Learning policy has been running for a sufficient time to collect needed information a report can be looked at by going to **Log & Report > Learning Report**.

The Report can be either a **Full Report** or a **Report Summary**

The time frame of the report can be **5 minutes**, **1 hour**, or **24 hours**.

The Learning Report includes:

Deployment Methodology

- Test Details
 - Start time
 - End time
 - Model
 - Firmware
- Policy List

Executive Summary

- Total Attacks Detected
- Top Application Category
- Top Web Category
- Top Web Domain
- Top Host by Bandwidth
- Host with Highest Session Count

Security and Threat Prevention

- High Risk Applications
- Application Vulnerability Exploits

- Malware, botnets and Spyware/Adware
- At-Risk Devices and Hosts

User Productivity

- Application Usage
 - Top Application Categories
 - Top Social Media Applications
 - Top Video/Audio Streaming Applications
 - Top Peer to Peer Applications
 - Top Gaming Applications
- Web Usage
 - Top Web Categories
 - Top Web Applications
 - Top Web Domains

Policy modes

You can operate your FortiGate or individual VDOMs in **Next Generation Firewall (NGFW) Policy Mode**.

You can enable NGFW policy mode by going to **System > Settings**, setting the **Inspection mode** to **Flow-based** and setting the NGFW mode to **Policy-based**. When selecting **NGFW policy-based** mode you also select the SSL/SSH Inspection mode that is applied to all policies

Flow-based inspection with profile-based **NGFW mode** is the default in FortiOS 5.6.

Or use the following CLI command:

```
config system settings
  set inspection-mode flow
  set ngfw-mode {profile-based | policy-based}
end
```

NGFW policy mode and NAT

If your FortiGate is operating in NAT mode, rather than enabling source NAT in individual NGFW policies you go to **Policy & Objects > Central SNAT** and add source NAT policies that apply to all matching traffic. In many cases you may only need one SNAT policy for each interface pair. For example, if you allow users on the internal network (connected to port1) to browse the Internet (connected to port2) you can add a port1 to port2 Central SNAT policy similar to the following:

New Central SNAT Policy

Incoming Interface	<div> port1</div> <div>+</div> <div>✕</div>
Outgoing Interface	<div> port2</div> <div>+</div> <div>✕</div>
Source address	<div> all</div> <div>+</div> <div>✕</div>
Destination address	<div> all</div> <div>+</div> <div>✕</div>

☒ NAT

IP Pool Configuration	<div>Use Outgoing Interface Address</div> <div>Use Dynamic IP Pool</div>
Protocol	<div>ANY</div> <div>TCP</div> <div>UDP</div> <div>SCTP</div> <div>Specify</div> <div>0</div>

Application control in NGFW policy mode

You configure **Application Control** simply by adding individual applications to security policies. You can set the action to accept or deny to allow or block the applications.

Name 	Block YouTube	
Incoming Interface	 port1	▼
Outgoing Interface	 port2	▼
Source	 all	✕
	+	
Destination	 all	✕
	+	
Schedule	 always	▼
Service	 ALL	✕
	+	
Application	 YouTube ✕  YouTube_Channel.Access ✕  YouTube_HD.Streaming ✕  YouTube_Video.Access ✕  YouTube_Video.Embedded ✕ +	
URL Category	+	
Action	 ACCEPT  DENY  LEARN	

Web filtering in NGFW mode

You configure **Web Filtering** by adding URL categories to security policies. You can set the action to accept or deny to allow or block the applications.

Name 	Block Streaming Websites	
Incoming Interface	 port1	▼
Outgoing Interface	 port2	▼
Source	 all	✕
	+	
Destination	 all	✕
	+	
Schedule	 always	▼
Service	 ALL	✕
	+	
Application	+	
URL Category	Streaming Media and Download	✕
	+	
Action	 ACCEPT  DENY  LEARN	

Other NGFW policy mode options

You can also combine both application control and web filtering in the same NGFW policy mode policy. Also if the policy accepts applications or URL categories you can also apply Antivirus, DNS Filtering, and IPS profiles in NGFW mode policies as well a logging and policy learning mode.

Security profiles

Where security policies provide the instructions to the FortiGate unit for controlling what traffic is allowed through the device, the Security profiles provide the screening that filters the content coming and going on the network. Security profiles enable you to instruct the FortiGate unit about what to look for in the traffic that you don't want, or want to monitor, as it passes through the device.

A security profile is a group of options and filters that you can apply to one or more firewall policies. Security profiles can be used by more than one security policy. You can configure sets of security profiles for the traffic types handled by a set of security policies that require identical protection levels and types, rather than repeatedly configuring those same security profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict antivirus protection, traffic between trusted internal addresses might need moderate antivirus protection. To provide the different levels of protection, you might configure two separate profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Security profiles are available for various unwanted traffic and network threats. Each are configured separately and can be used in different groupings as needed. You configure security profiles in the Security Profiles menu and applied when creating a security policy by selecting the security profile type.

There is a separate handbook for the topic of the Security Profiles, but because the Security Profiles are applied through the Firewall policies it makes sense to have at least a basic idea of what the security profile do and how they integrate into the FortiGate's firewall policies. The following is a listing and a brief description of what the security profiles offer by way of functionality and how they can be configured into the firewall policies.

- HTTP
- SMTP
- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS
- IM

AntiVirus

Antivirus is used as a catch all term to describe the technology for protection against the transmission of malicious computer code sometimes referred to as malware. As anyone who has listened to the media has heard that the Internet can be a dangerous place filled with malware of various flavors. Currently, the malware that is most common in the Internet, in descending order, is Trojan horses, viruses, worms, adware, back door exploits, spyware and other variations. In recent years, not only has the volume of malicious software become greater than would have been believed when it first appeared but the level of sophistication has risen as well.

The Antivirus Filter works by inspecting the traffic that is about to be transmitted through the FortiGate. To increase the efficiency of effort it only inspects the traffic being transmitted via the protocols that it has been configured to check. Before the data moves across the FortiGate firewall from one interface to another it is checked for attributes or signatures that have been known to be associated with malware. If malware is detected, it is removed.

Web Filtering

Malicious code is not the only thing to be wary of on the Internet. There is also the actual content. While the content will not damage or steal information from your computer there is still a number of reasons that would require protection from it.

In a setting where there are children or other sensitive people using the access provided by a connected computer there is a need to make sure that images or information that is not appropriate is not inadvertently displayed to them. Even if there is supervision, in the time it takes to recognize something that is inappropriate and then properly react can expose those we wish to protect. It is more efficient to make sure that the content cannot reach the screen in the first place.

In an organizational setting, there is still the expectation that organization will do what it can to prevent inappropriate content from getting onto the computer screens and thus provoking an Human Resources incident. There is also the potential loss of productivity that can take place if people have unfiltered access to the Internet. Some organizations prefer to limit the amount of distractions available to tempt their workers away from their duties.

The Web filter works primarily by looking at the destination location request for a HTTP(S) request made by the sending computer. If the URL is on a list that you have configured to list unwanted sites, the connection will be disallowed. If the site is part of a category of sites that you have configured to deny connections to the session will also be denied. You can also configure the content filter to check for specific key strings of data on the actual web site and if any of those strings of data appear the connection will not be allowed.

The configuration for each of these protocols is handled separately.

DNS filtering is similar to Web Filtering from the viewpoint of the user. The difference is under the hood. When using regular Web Filtering, the traffic can go through some processing steps before it gets to the point where the web filter determines whether or not the traffic should be accepted or denied. Because the filtering takes place at the DNS level, some sites can be denied before a lot of the additional processing takes place. This can save resource usage on the FortiGate and help performance.

Application Control

Application Control is designed to allow you to determine what applications are operating on your network and to also filter the use of these applications as required. Application control is also for outgoing traffic to prevent the use of applications that are against an organization's policy from crossing the network gateway to other networks. An example of this would be the use of proxy servers to circumvent the restrictions put in place using the Web Filtering.

Intrusion Protection (IPS)

Intrusion Prevention System is almost self explanatory. In the same way that there is malware out on the Internet that the network needs to be protected from there are also people out there that take a more targeted approach to malicious cyber activity. No operating system is perfect and new vulnerabilities are being discovered all of the time. An intrusion prevention system is designed to look for activity or behavior that is consistent with attacks against your network. When attack like behavior is detected it can either be dropped or just monitored depending on the approach that you would like to take.

As new vulnerabilities are discovered they can be added to the IPS database so that the protection is current.

Anti-Spam

Spam or unsolicited bulk email is said to account for approximately 90% of the email traffic on the Internet. Sorting through it is both time consuming and frustrating. By putting an email filter on policies that handle email traffic, the amount of spam that users have to deal with can be greatly reduced.

Data Leak Prevention (DLP)

Data Leak Prevention is used to prevent sensitive information from leaving your network. When people think of security in the cyber-world one of the most common images is that of a hacker penetrating your network and making off with your sensitive information, but the other way that you can lose sensitive data is if someone already on the inside of your network sends it out. This does not have to be an act of industrial espionage. It can just be a case of not knowing the policies of the organization or a lack of knowledge of security or laws concerning privacy.

For instance, a company may have a policy that they will not reveal anyone's Social Security number, but an employee emails a number of documents to another company that included a lengthy document that has a Social Security number buried deep within it. There is not malicious intent but if the information got out there could be repercussions.

If an organization has any information in a digital format that it cannot afford for financial or legal reasons, to leave its network, it makes sense to have Data Leak Prevention in place as an additional layer of protection.

VoIP

Voice over IP is essentially the protocols for transmitting voice or other multimedia communications over Internet Protocol networks such as the Internet. The Security Profiles VoIP options apply the SIP Application Level Gateway (ALG) to support SIP through the FortiGate unit. The SIP ALG can also be used to protect networks from SIP-based attacks.

ICAP

Internet Content Adaptation Protocol (ICAP) off loads HTTP traffic to another location for specialized processing. The purpose of this module when triggered is to send the incoming HTTP traffic over to a remote server to be processed thus taking some of the strain off of the resources of the FortiGate unit. The reasons for the specialized process could be anything from more sophisticated Antivirus to manipulation of the HTTP headers and URLs.

Just like other components of the FortiGate, there is the option for different Proxy Option profiles so that you can be very granular in your control of the workings of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

The Web Application Firewall performs a similar role as devices such as Fortinet's FortiWeb, though in a more limited fashion. Its function is to protect internal web servers from malicious activity specific to those types of servers. This includes things like SQL injection, Cross site Scripting and trojans. It uses signatures and other straight forward methods to protect the web servers, but it is a case of turning the feature on or off and the actions are limited to **Allow**, **Monitor** or **Block**. To get protection that is more sophisticated, granular and intelligent, as well as having many more features, it is necessary to get a device like the FortiWeb that can devote more resources to the process. However, if your needs are simple, choosing to use the WAF feature built into the FortiGate should provide valuable protection.

The comfort client feature mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete so as to let the user know that processing is taking place and that there hasn't been a failure in the transmission. This slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned without any indication of viruses the transfer will proceed at full speed.

Security profile groups

It may seem counter intuitive to have a topic on security profile groups in the Firewall Chapter/Handbook when there is already a chapter/handbook on Security Profiles, but there are reasons.

- Security profile groups are used exclusively in the configuration of a firewall policy, which is described in the Firewall Chapter/Handbook.
- The CLI commands for creating and using security profile groups are in the firewall configuration context of the command line structure of settings.

The purpose of security profile groups is just the same as other groups such as Address, Service, and VIP groups. They are used to save time and effort in the administration of the FortiGate when there are a lot of policies with a similar pattern of Security Profile use. In a fairly basic network setup with a handful of policies it doesn't seem like it would be worth the effort to set up groups of security profiles but if you have a large complex configuration with

hundreds of policies where many of them use the same security profiles it can definitely save some effort and help prevent missing adding an important profile from a policy. As an added benefit, when it comes time to add or change the profiles for the policies that use the Security Profile Groups, the changes only have to be made to the group, not each policy.

The most difficult part about using security profile groups is making them visible in the GUI.

Making security profile groups visible in the GUI

By default, the Security Profile Groups are not visible in the GUI. Neither the ability to assign one to a policy nor the ability to configure the members of a group are available by default. You will not find the option to enable Security Profile Groups under **System > Feature Visibility** either. Instead, they only become visible in the GUI once one has been created and assigned to a policy. This must be done the first time through the CLI using the following syntax:

```
config system settings
    set gui-dynamic-profile-display enable
end
```

Step 1 - Create a security profile group:

Enter the command:

```
config firewall profile-group
```

Use the edit command to give a name to and create a new Security Profile Group

```
(profile-group) # edit test-group
```

Configure the members of the group by setting the name of the desired profile in the field for the related profile/sensor/list. The options are:

av-profile	Name of an existing Antivirus profile.
webfilter-profile	Name of an existing Web filter profile.
dnsfilter-profile	Name of an existing DNS filter profile.
spamfilter-profile	Name of an existing Spam filter profile.
dlp-sensor	Name of an existing DLP sensor.
ips-sensor	Name of an existing IPS sensor.
application-list	Name of an existing Application list.
voip-profile	Name of an existing VoIP profile.
icap-profile	Name of an existing ICAP profile.
waf-profile	Name of an existing Web application firewall profile.
profile-protocol-options	Name of an existing Protocol options profile.
ssl-ssh-profile	Name of an existing SSL SSH profile.

Example:

```
set av-profile default
set profile-protocol-options default
end
```

Always set the `profile-protocol-options` setting before attempting to save the profile group. If this is not set, you will get the error:

```
node_check_object fail! for profile-protocol-options
Attribute 'profile-protocol-options' MUST be set.
Command fail. Return code -56
```

Step 2 - Add a security profile to a policy

Now that there is group to add to a policy we can configure a policy to allow the use of a Security Policy group. This is also done in the CLI.

In the following example only the command necessary to enable the use and pick of a Security Policy group have been listed.

```
config firewall policy
edit 0
set utm-status enable
set profile-type group
set profile-group test-group
```

Step 3 - The appearance in the GUI of the security profile group configuration features

- Under **Security Profiles** there is a menu item called **Profile Groups** that can be used to create new and edit existing profile groups.
- In the **Edit Policy** window for **IPv4** and **IPv6** policies there is a **Use Security Profile Group** field to enable or disable the use of the groups.
 - In the window, policy groups can be created or edited by clicking on the appropriate icons next to or in the drop down menu
- In the policy listing window there is a Security Profiles column.
 - Right or left clicking on the icon for the group brings up editing options either via a slide out window or a drop down menu, respectively.

Proxy option components

Any time a security profile that requires the use of a proxy is enabled the Proxy Options field will be displayed. Certain inspections defined in security profiles require that the traffic be held in proxy while the inspection is carried out and so the Proxy Options are there to define the parameters of how the traffic will be processed and to what level the traffic will be processed. In the same way that there can be multiple security profiles of a single type there can also be a number of unique Proxy Option profiles so that as the requirements for a policy differ from one policy to the next you can also configure a different Proxy Option profile for each individual policy or you can use one profile repeatedly.

The Proxy Options refer to the handling of the following protocols:

- HTTP
- SMTP
- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS
- IM

The configuration for each of these protocols is handled separately.

It should also be noted that these configurations apply to only the Security Profiles Proxy-based processes and not the Flow-based processes.

The use of different proxy profiles and profile options

Just like other components of the FortiGate, there is the option for different Proxy Option profiles so that you can be very granular in your control of the workings of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

Oversized file log

This setting is for those that would like to log the occurrence of oversized files being processed. It does not change how they are processed it only enables the FortiGate unit to log that they were either blocked or allowed through. A common practice is to allow larger files through without antivirus processing. This allows you to get an idea of how often this happens and decide on whether or not to alter the settings relating to the treatment of oversized files.

The setting of the threshold for what is considered to be an oversized file is located in the Oversized File / Email Threshold that is found in some of the protocol options for the Proxy Options.

Protocol port mapping

While each of the protocols listed has a default TCP port that is commonly used, the level of granularity of control on the FortiGate firewall allows that the port used by the protocols can be individually modified in each separate Profile. It can also be set to inspect any port with flowing traffic for that particular protocol. The headers of the packets will indicate which protocol generated the packet. To optimize the resources of the unit the mapping and inspection of protocols can be enabled or disabled depending on your requirements.

Comfort clients

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit begins scanning the file. During the buffering and scanning procedure, the user must wait. After the scan is completed, if no infection is found, the file is sent to the next step in the process flow. If the file is a large one this part of the process can take some time. In some cases enough time that some users may get impatient and cancel the download.

The comfort client feature mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete so as to let the user know that processing is taking place and that there hasn't been a failure in the transmission. This slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned without any indication of viruses the transfer will proceed at full speed.

If there is evidence of an infection the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file. If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Buffering the entire file allows the FortiGate unit to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Oversized file/email threshold

This is another feature that is related to antivirus scanning. The FortiGate unit has a finite amount of resources that can be used to buffer and scan a file. If a large file such as an ISO image or video file was to be downloaded this could not only overwhelm the memory of the FortiGate, especially if there were other large files being downloaded at the same time, but could exceed it as well. For this reason, how to treat large files needs to be addressed.

A threshold is assigned to determine what should be considered an oversized file or email. This can be set at any size from 1 MB to 50 MB. Any file or email over this threshold will not be processed by the Antivirus Security Profiles. Once a file is determined to be oversized it must be then determined whether to allow it or to block it.

These settings are not a technical decision but a policy one that will depend on your comfort level with letting files into your network. As there often is, there is a compromise between convenience or ease of use and security. If you want to go for a high peace of mind level you can configure the firewall to block oversized files and thus no files would be coming into the network that have not been scanned. If you are looking for optimizing the memory of the FortiGate unit and making sure that everybody is getting the files they want, you can lower the threshold and allow files that are over the threshold.

It should be noted that in terms of probability that malware is more likely to be found in smaller files than in larger files. A number of administrators take this into account when they lower the default threshold so as to lessen the impact on memory if they see the FortiGate unit going into conserve mode on a regular basis.

Chunked bypass

The HTTP section allows the enabling of "Chunked Bypass". This refers to the mechanism in version 1.1 of HTTP that allows a web server to start sending chunks of dynamically generated output in response to a request before actually knowing the actual size of the content. Where dynamically generated content is concerned this means

that there is a faster initial response to HTTP requests. From a security stand point it means that the content will not be held in the proxy as an entire file before proceeding.

Allow fragmented messages

The specifications of RFC 2046 allow for the breaking up of emails and sending the fragments in parallel to be rebuilt and read at the other end by the mail server. It was originally designed to increase the performance over slower connections where larger email messages were involved. It will depend on your mail configuration if this is even possible for your network but outside of Microsoft Outlook and Outlook Express, not many email clients are set up to break up messages like this. The drawback of allowing this feature is that if malware is broken up between multiple fragments of the message the risk is run that it will not be detected by some antivirus configurations because the code may not all be present at the same time to identify.

Append email signature

The Append Email Signature is used when an organization would like to ensure that over and above our in this case underneath the existing personal signatures of the sender, all of the emails going out of their network have the appropriate “boilerplate”, for lack of a better term. These appended emails do not replace existing signatures. They are as the feature states, appended to the email.

Examples could include things like:

- Without prior approval the email should not be forwarded.
- Please be environmentally friendly and don't print out emails
- For questions regarding the purchasing of our products please call...

It can be anything that the organization would like as long as it is in text format. The use of this feature usually works best in an environment where there is some standardization of what goes into the personal signatures of the senders so that there is no duplication or contradiction of information in the signatures.

SSL/SSH inspection

While the profile configuration for **SSL/SSH Inspection** is found in the **Security Profiles** section it is enabled in the firewall policy by enabling any of the security profiles. Choosing which of the **SSL/SSH Inspection** profiles is all that can really be done in the policy.

The reason for having this inspection as part of the policy is the wide spread use of encryption by both legitimate and malicious actors. The legitimate users of the Internet use encryption to hide their information from snooping bad guy but the bad guys use encryption to hide their malicious content from being scanned for viruses and other malicious code by security devices.

By using the correct SSL certificates, the FortiGate can open up encrypted traffic and inspect it for malicious content that would otherwise make it past the other profiles because they couldn't read the encrypted traffic.

There are two basic types of inspection:

- Certificate inspection, which only looks at the certificate that encrypted the packets to make sure that it is a recognized and valid certificate.
- Full inspection, or deep inspection, that looks at all of the content of the packet. While more thorough, it also takes up more resources to perform.

HTTP Strict Transport Security (HSTS) Protocol

HSTS is a protocol used by Google and other web browsers to prevent man-in-the-middle attacks.

When performing deep inspection, the FortiGate intercepts the https traffic and would send its own self-signed CA certificate to the browser. If the browser is configured to use HSTS connections, it would refuse the FortiGate CA certificate since it is not on the trusted list for Google servers.

To keep the CA certificate from being refused, the HSTS settings should be cleared from the browser. Instructions for this vary between browsers.

SSH MITM deep inspection

Due to an increase, in recent years of vulnerabilities discovered in the SSH protocol, protections have been incorporated into FortiOS's Intrusion Prevention System (IPS) engine that will aid in protecting against malicious activity coming through the FortiGate against SSH access points. In addition to the protections offered by IPS, additional settings and functionality have been added to protect against man-in-the-middle (MITM) attacks that use SSH as the attack vector.

These protections include support for comprehensive security controls on SSH MITM deep inspections:

- SSH filter profile to control SSH tunnel types and filtering on SSH shell commands.
- SSH proxy policy that can apply a proxy firewall policy or firewall policy using SSH inspection, with user authentication to SSH sessions.
- Support for SSH tunnel policy access control for TCP/IP port forwarding traffic tunneled through SSH proxy. This allows IPS scanning to be applied to the tunneled traffic.
- Support the use of SSH trust status to detect and prevent SSH-based MITM attacks.

Support SSH proxy policy for SSH sessions

Policy check

To enable SSH proxy-policy or SSH tunnel-policy, `ssh-policy-check` or `ssh-tun-policy-check` must be enabled under `ssl-ssh-profile` for the corresponding firewall policy.

```
config firewall ssl-ssh-profile
  edit <name>
    config ssh
      set ssh-policy-check [disable|enable]
      set ssh-tun-policy-check [disable|enable]
    end
  end
```

SSH proxy option

Set the proxy type to `ssh` in `config firewall proxy-policy`.

```
config firewall proxy-policy
  edit <pol-id>
    set proxy ssh
    set action {accept|deny}
    set utm-status enable
    set ssh-filter-profile <profile_name>
  end
```

Authentication for SSH

When `user` or `user-group` is set in SSH proxy policy, firewall authentication can be implemented for SSH proxy traffic.

```
config authentication rule
edit <name>
set protocol ssh
end
```

Basic authentication scheme:

```
config authentication scheme
edit "ssh-active"
set method basic
set user-database "local" #or LDAP server
end
```

Under authentication for SSH, with basic authentication scheme, the client is expected to input username/password in the format of:

- `<firewall username>:<server username>`
- `<firewall password>:<server password>`

SSH-publickey authentication scheme:

```
config authentication scheme
edit "ssh-pkey"
set method ssh-publickey
set user-database "local"
set ssh-ca "server-ca"
end
```

The user name is embedded in `ssh-publickey`. The user group information will be retrieved if the public key is validated by CA.

FortiOS currently only supports validation by using CA. The CA needs to be configured under `config firewall ssh local-ca`.

Private-key is not required for client public-key authentication. Once the client offers the public-key signed by the set CA will be authenticated.

Both basic and SSH-publickey authentication scheme:

```
config authentication scheme
edit "ssh-pkey"
set method basic ssh-publickey
set user-database "local"
set ssh-ca "server-ca"
end
```

Support SSH tunnel policy to do access control for TCP/IP port forwarding traffic.

Add a proxy type `ssh-tunnel` into config firewall proxy-policy

```
config firewall proxy-policy
```

```
edit <pol-id>
  set proxy ssh-tunnel
  set action {accept | deny}
  set utm-status enable
```

The feature supports allowing or denying based on the IPS sensor/app-control applied to the traffic.

```
set ips-sensor <sensor_profile_name>
set application-list <application_control_list>
end
```

Support SSH trust to detect and prevent from SSH MITM attacks

Define trusted SSH host key for specific SSH server

```
config firewall ssh host-key
  edit <name>
    set status {trusted|revoked}
    set type {RSA|DSS|ECDSA}
    set nid <NID of ECDSA key>
    set ip <ip>
    set port <port>
    set hostname <name>
    set public-key <host key>
  end
```

Define trusted/untrusted CAs for host key signing.

Any host key signed by trust CA is trusted unless the host key is revoked.

```
config firewall ssh local-ca
  edit <name>
    set password <passwd>
    set public-key <public key>
    set private-key <private key>
    set source {built-in|user}
  end
```

- The system creates two built-in SSH CAs:
 - Fortinet_SSH_CA
 - Fortinet_SSH_CA_Untrusted.
- The CAs are used to re-sign a server host key with local host-key using trusted/untrusted CA when the server host key is trusted or untrusted.

Define local hostkey templates for trusted re-signing.

By default, the local hostkey templates are generated automatically.

```
config firewall ssh local-key
  edit <name>
    set status [trusted|revoked]
    set type [RSA|DSA|ECDSA|ED25519|RSA-CA|DSA-CA|ECDSA-CA|ED25519-CA]
    set nid <NID of ECDSA key>
    set ip <ip>
    set port <port>
```

```

set hostname <name>
set password <passwd>
set public-key <public key>
set private-key <private key>
set source {build-in|user}
end

```

Per VDOM SSH settings

```

config firewall ssh setting
set caname <trusted-ca>
set untrusted-caname <untrusted-ca>
set hostkey-rsa <hostkey-rsa>
set hostkey-dss <hostkey-dss>
set hostkey-ecdsa256 <hostkey-ecdsa256>
set hostkey-ecdsa384 <hostkey-ecdsa384>
set ed25519-key <ed25519-key>
set host-trusted-check {enable|disble}
end

```

- When a host key is trusted and signed by a CA, SSH proxy re-signs according to the type of hostkey using trusted CA.
- When a host is trusted but not signed, SSH proxy sends back according type of hostkey.
- When a host key is untrusted and signed by a CA, SSH proxy re-signs a temporary host key (1 hour) using untrusted CA.
- When a host is trusted but not signed, SSH proxy sends back a temporary host key (1 hour).

Add SSH filter profile table

Support options to block/log "x11-filter/ssh-shell/exec/port-forward/sftp"

```

config ssh-filter profile
edit <name>
set block {x11|shell|exec|port-forward|tun-forward|sftp|unknown}+
set log {x11|shell|exec|port-forward|tun-forward|sftp|unknown}+
end

```

Add shell command filters

```

config ssh-filter profile
edit <name>
config shell-commands
edit <id>
set type {simple|regex}
set pattern <cmd-string>
set action {block|allow}

```

```
set log {block|allow}
set alert {block|allow}
set severity {low|medium|high|critical}
end
set default-command-log {block|allow}
end
```

Mirroring SSL inspected traffic

It is possible to "mirror" or send a copy of traffic decrypted by SSL inspection to one or more FortiGate interfaces so that the traffic can be collected by a raw packet capture tool for archiving or analysis. The mirroring occurs after being processed by the SSL decoder and in the same point in the work flow as the decryption of application data. The decrypted application data is wrapped inside a TCP packet (with IP and Ethernet headers), and then sent to the mirror port.

This feature works when the inspection mode is set to flow-based or proxy-based, but not for explicit proxy.

Decryption, storage, inspection, and use decrypted content is subject to local privacy rules. Use of these features could enable malicious users with administrative access to your FortiGate to harvest sensitive information submitted using an encrypted channel.

In this example, the setting enables the policy to send all traffic decrypted by the policy to the FortiGate port1 and port2 interfaces.

```
config firewall policy
edit 0
set ssl-mirror enable
set ssl-mirror-intf port1 port2
end
```

Encryption strength for proxied SSH sessions

The level of SSH encryption can be set for SSH sessions on a per-profile basis.

Encryption Level	Description
compatible	This level allows for a broader set of encryption algorithms to be used and is better for compatibility.
high-encryption	This level will only allow AES-CTR, AES-GCM and high encryption algorithms to be used for the session.

Syntax:

```
config firewall ssl-ssh-profile
edit <profile name>
config ssh
set ssh-algorithm {compatible|high-encryption}
end
end
```

RPC over HTTP

How protocol options profiles and SSL inspection profiles handle RPC (Remote Procedure Calls) over HTTP traffic can be configured separately from normal HTTP traffic. The configuration is done in the CLI.

Configuration in protocol options

```
config firewall profile-protocol-options
edit 0
set rpc-over-http [disable|enable]
end
```

Configuration in SSL/SSH inspection

```
config firewall ssl-ssh-profile
edit deep inspection
set rpc-over-http [disable|enable]
end
```

NAT

NAT or Network Address Translation is the process that enables a single device such as a router or firewall to act as an agent between the Internet or Public Network and a local or private network. This “agent”, in real time, translates the source IP address of a device on one network interface, usually the Internal, to a different IP address as it leaves another interface, usually the interface connected to the ISP and the Internet. This enables a single public address to represent a significantly larger number of private addresses.

The origins of NAT

In order to understand NAT it helps to know why it was created. At one time, every computer that was part of a network had to have its own addresses so that the other computers could talk to it. There were a few protocols in use at the time, some of which were only for use on a single network, but of those that were routable, the one that had become the standard for the Internet was IP (Internet Protocol) version 4.

When IP version 4 addressing was created nobody had any idea how many addresses would be needed. The total address range was based on the concept of 2 to the 32nd power, which works out to be 4 294 967 296 potential addresses. Once you eliminate some of those for reserved addresses, broadcast addresses, network addresses, multicasting, etc., you end up with a workable scope of about 3.2 million addressees. This was thought to be more than enough at the time. The designers were not expecting the explosion of personal computing, the World Wide Web or smart phones. As of the beginning of 2012, some estimate the number of computers in the world in the neighborhood of 1 billion, and most of those computer users are going to want to be on the Internet or Search the World Wide Web. In short, we ran out of addresses.

This problem of an address shortage was realized before we actually ran out, and in the mid 1990s 2 technical papers called RFCs numbered 1631 (<http://www.ietf.org/rfc/rfc1631.txt>) and 1918 (<http://tools.ietf.org/html/rfc1918>), proposed components of a method that would be used as a solution until a new addressing methodology could be implemented across the Internet infrastructure. For more information on this you can look up IP version 6.

RFC 1631 described a process that would allow networking devices to translate a single public address to multiple private IP addresses and RFC 1918 laid out the use of the private addresses. The addresses that were on the Internet (Public IP addresses) could not be duplicated for them to work as unique addresses, but behind a

firewall, which most large institutions had, they could use their own Private IP addresses for internal use and the internal computers could share the external or Public IP address.

To give an idea on a small scale how this works, image that a company has a need for 200 computer addresses. Before Private IP addresses and NAT the company would have purchased a full Class C address range which would have been 254 usable IP addresses; wasting about 50 addresses. Now with NAT, that company only needs 1 IP address for its 200 computers and this leaves the rest of the IP addresses in that range available for other companies to do the same thing.

NAT gives better value than it would first appear because it is not 253 companies that can use 254 addresses but each of those 254 companies could set up their networking infrastructures to use up to thousands of Private IP addresses, more if they don't all have to talk to the Internet at the same time. This process enabled the Internet to keep growing even though we technically have many more computers networked than we have addresses.

Dynamic NAT

Dynamic NAT maps the private IP addresses to the first available Public Address from a pool of possible Addresses. In the FortiGate firewall this can be done by using IP Pools.

Overloading

This is a form of Dynamic NAT that maps multiple private IP address to a single Public IP address but differentiates them by using a different port assignment. This is probably the most widely used version of NAT. This is also referred to as PAT (Port Address Translation) or Masquerading.

An example would be if you had a single IP address assigned to you by your ISP but had 50 or 60 computers on your local network.

Say the internal address of the interface connected to the ISP was 256.16.32.65 (again an impossible address) with 256.16.32.64 being the remote gateway. If you are using this form of NAT any time one of your computers accesses the Internet it will be seen from the Internet as 256.16.32.65. If you wish to test this go to 2 different computers and verify that they each have a different private IP address then go to a site that tells you your IP address such as www.ipchicken.com. You will see that the site gives the same result of 256.16.32.65, if it existed, as the public address for both computers.

As mentioned before this is sometimes called Port Address Translation because network device uses TCP ports to determine which internal IP address is associated with each session through the network device. For example, if you have a network with internal addresses ranging from 192.168.1.1 to 192.168.1.255 and you have 5 computers all trying to connect to a web site which is normally listening on port 80 all of them will appear to the remote web site to have the IP address of 256.16.32.65 but they will each have a different sending TCP port, with the port numbers being somewhere between 1 and 65 535, although the port numbers between 1 to 1024 are usually reserved or already in use. So it could be something like the following:

192.168.1.10	256.16.32.65:	port 486
192.168.1.23	256.16.32.65:	port 2409
192.168.1.56	256.16.32.65:	port 53763
192.168.1.109	256.16.32.65:	port 5548
192.168.1.201	256.16.32.65:	port 4396

And the remote web server would send the responding traffic back based on those port numbers so the network device would be able to sort through the incoming traffic and pass it on to the correct computer.

Overlapping

Because everybody is using the relative same small selection of Private IP addresses it is inevitable that there will be two networks that share the same network range that will need to talk with each other. This happens most often over Virtual Private Networks or when one organization ends up merging with another. This is a case where a private IP address may be translated into a different private IP address so there are no issues with conflict of addresses or confusion in terms of routing.

An example of this would be when you have a Main office that is using an IP range of 172.16.0.1 to 172.20.255.255 connecting through a VPN to a recently acquired branch office that is already running with an IP range of 172.17.1.1 to 172.17.255.255. Both of these ranges are perfectly valid but because the Branch office range is included in the Main Office range any time the system from the Main office try to connect to an address in the Branch Office the routing the system will not send the packet to the default gateway because according to the routing table the address is in its own subnet.

The plan here would be to NAT in both directions so that traffic from neither side of the firewall would be in conflict and they would be able to route the traffic. Everything coming from the Branch Office could be assigned an address in the 192.168.1.1 to 192.168.1.255 range and everything from the Main office going to the Branch Office could be assigned to an address in the 192.168.10.1 to 192.168.10.255 range.

Static NAT

In Static NAT one internal IP address is always mapped to the same public IP address.

In FortiGate firewall configurations this is most commonly done with the use of Virtual IP addressing.

An example would be if you had a small range of IP addresses assigned to you by your ISP and you wished to use one of those IP address exclusively for a particular server such as an email server.

Say the internal address of the Email server was 192.168.12.25 and the Public IP address from your assigned addresses range from 256.16.32.65 to 256.16.32.127. Many readers will notice that because one of the numbers is above 255 that this is not a real Public IP address. The Address that you have assigned to the interface connected to your ISP is 256.16.32.66, with 256.16.32.65 being the remote gateway. You wish to use the address of 256.16.32.70 exclusively for your email server.

When using a Virtual IP address you set the external IP address of 256.16.32.70 to map to 192.168.12.25. This means that any traffic being sent to the public address of 256.16.32.70 will be directed to the internal computer at the address of 192.168.12.25

When using a Virtual IP address, this will have the added function that when ever traffic goes from 192.168.12.25 to the Internet it will appear to the recipient of that traffic at the other end as coming from 256.16.32.70.

You should note that if you use Virtual IP addressing with the Port Forwarding enabled you do not get this reciprocal effect and must use IP pools to make sure that the outbound traffic uses the specified IP address.

Benefits of NAT

More IP addresses available while conserving public IP addresses

As explained earlier, this was the original intent of the technology and does not need to be gone into further.

Financial savings

Because an organization does not have to purchase IP addresses for every computer in use there is a significant cost savings due to using the process of Network Address Translation.

Security enhancements

One of the side benefits of the process of NAT is an improvement in security. Individual computers are harder to target from the outside and if port forwarding is being used computers on the inside of a firewall are less likely to have unmonitored open ports accessible from the Internet.

Ease of compartmentalization of your network

With a large available pool of IP addresses to use internally a network administrator can arrange things to be compartmentalized in a rational and easily remembered fashion and networks can be broken apart easily to isolate for reasons of network performance and security.

Example

You have a large organization that for security reasons has certain departments that do not share network resources.

You can have the main section of the organization set up as follows;

Network Devices	192.168.1.1 to 192.168.1.25
Internal Servers	192.168.1.26 to 192.168.1.50
Printers	192.168.1.51 to 192.168.1.75
Administration Personnel	192.168.1.76 to 192.168.1.100
Sales People	192.168.1.101 to 192.168.1.200
Marketing	192.168.1.201 to 192.168.1.250

You could then have the following groups broken off into separate subnets:

Accounting	192.168.100.1 to 192.168.100.255
Research and Development	172.16.1.1 to 172.16.255.255
Executive Management	192.168.50.1 to 192.168.50.255
Web sites and Email Servers	10.0.50.1 to 10.0.50.255

These addresses do not have to be assigned right away but can be used as planned ranges.

NAT in transparent mode

Similar to operating in NAT mode, when operating a FortiGate unit in transparent mode you can add security policies and:

- Enable NAT to translate the source addresses of packets as they pass through the FortiGate unit.
- Add virtual IPs to translate destination addresses of packets as they pass through the FortiGate unit.
- Add IP pools as required for source address translation

A FortiGate unit operating in transparent mode normally has only one IP address - the management IP. To support NAT in transparent mode, you can add a second management IP. These two management IPs must be on different subnets. When you add two management IP addresses, all FortiGate unit network interfaces will respond to connections to both of these IP addresses.

Use the following steps to configure NAT in transparent mode:

1. Add two management IPs
2. Add an IP pool to the WAN1 interface
3. Add an Internal to WAN1 security policy

You can add the security policy from the web-based manager and then use the CLI to enable NAT and add the IP pool.

The usual practice of NATing in transparent mode makes use of two management IP addresses that are on different subnets, but this is not an essential requirement in every case.

If there is a router between the client systems and the FortiGate unit you can use the router's capabilities of tracking sessions to assign NATed addresses from an IP pool to the clients even if the assigned address don't belong to a subnet on your network.

Example

Client computer has an IP address of 1.1.1.33 on the subnet 1.1.1.0/24.

Router "A" sits between the client computer and the FortiGate (in transparent mode) with the IP address of 1.1.1.1 on the client's side of the router and the IP address of 192.168.1.211 on the FortiGate's side of the router.

Use NAT to assign addresses from an address pool of 9.9.9.1 to 9.9.9.99 to traffic coming from gateway of 192.168.1.211.

To enable the return traffic to get to the original computer, set up a static route that assigns any traffic with a destination of 9.9.9.0/24 to go through the 192.168.1.211 gateway. As long as the session for the outgoing traffic has been maintained, communication between the client computer and the external system on the other side of the FortiGate will work.

Central NAT table

The central NAT table enables you to define, and control with more granularity, the address translation performed by the FortiGate unit. With the NAT table, you can define the rules which dictate the source address or address group and which IP pool the destination address uses.

While similar in functionality to IP pools, where a single address is translated to an alternate address from a range of IP addresses, with IP pools there is no control over the translated port. When using the IP pool for source NAT, you can define a fixed port to guarantee the source port number is unchanged. If no fix port is defined, the port translation is randomly chosen by the FortiGate unit. With the central NAT table, you have full control over both the IP address and port translation.

The FortiGate unit reads the NAT rules in a top-down methodology, until it hits a matching rule for the incoming address. This enables you to create multiple NAT policies that dictate which IP pool is used based on the source

address. The NAT policies can be rearranged within the policy list as well. NAT policies are applied to network traffic after a security policy.

NAT64 and NAT46

NAT64 and NAT46 are the terms used to refer to the mechanism that allows IPv6 addressed hosts to communicate with IPv4 addressed hosts and vice versa. Without such a mechanism an IPv6 node on a network such as a corporate LAN would not be able to communicate with a web site that was still in a IPv4 only environment and IPv4 environments would not be able to connect to IPv6 networks.

One of these setups involves having at least 2 interfaces, 1 on an IPv4 network and 1 on an IPv6 network. The NAT64 server synthesizes AAAA records, used by IPv6 from A records used by IPv4. This way client-server and peer to peer communications will be able to work between an IPv6 only client and an IPv4 server without making changes to either of the end nodes in the communication transaction. The IPv6 network attached to the FortiGate unit should be a 32 bit segment, (for instance 64:ff9b::/96, see RFC 6052 and RFC 6146). IPv4 address will be embedded into the communications from the IPv6 client.

Because the IPv6 range of addresses is so much larger than the IPv4 range, a one to one mapping is not feasible. Therefore the NAT64 function is required to maintain any IPv6 to IPv4 mappings that it synthesizes. This can be done either statically by the administrator or automatically by the service as the packets from the IPv6 network go through the device. The first method would be a stateless translation and the second would be a stateful translation. NAT64 is designed for communication initiated from IPv6 hosts to IPv4 addresses. It is address mapping like this that allows the reverse to occur between established connections. The stateless or manual method is an appropriate solution when the NAT64 translation is taking place in front of legacy IPv4 servers to allow those specific servers to be accessed by remote IPv6-only clients. The stateful or automatic solution is best used closer to the client side when you have to allow some specific IPv6 clients to talk to any of the IPv4-only servers on the Internet.

There are currently issues with NAT64 not being able to make everything accessible. Examples would be SIP, Skype, MSN, Goggle talk, and sites with IPv4 literals. IPv4 literals being IPv4 addresses that are imbedded into content rather than a FQDN.

Policies that employ NAT64 or NAT46 can be configured from the web-based manager as long as the feature is enabled using the Features setting found at **System > Config > Features**.

- To create a NAT64 policy go to **Policy & Objects > NAT64 Policy** and select **Create New**.
- To create a NAT46 policy go to **Policy > NAT46 Policy** and select **Create New**.

The difference between these NAT policies and regular policies is that there is no option to use the security profiles and sensors.

NAT64 CLAT traffic is now supported by the FortiGate. CLAT traffic comes from devices that use the SIIT translator that plays a part in affecting IPv6 - IPv4 NAT translation.

NAT64 CLAT

NAT64 CLAT traffic is supported by FortiOS. CLAT traffic comes from devices that use the SIIT translator that plays a part in affecting IPv6 - IPv4 NAT translation.

NAT66

NAT66 is Network Address Translation between 2 IPv6 network. The basic idea behind NAT66 is no different than the regular NAT between IPv4 networks that we are all used to. The difference are in the mechanics of how it is performed, mainly because of the complexity and size of the addresses that are being dealt with.

In an IPv4 world, the reason for the use of NAT was usually one or a combination of the following 3 reasons:

- Improved security - actual addresses behind NAT are virtually hidden
- Amplification of addresses - hundreds of computers can use as little as a single public IP address
- Internal address stability - there is control of internal addressing. The addresses can stay the same even if Internet Service Providers change.

In these days of security awareness the protective properties of NAT are not something that are not normally depended on by themselves to defend a network and with the vastly enlarged IPv6 address scope there is no longer a need to amplify the available addresses. However, the desire to have internal address control still exists. The most common reason for using NAT66 is likely to be the maintaining of the existing address scheme of the internal network despite changes outside of it. Imagine that you have an internal network of 2000 IP addresses and one day the company changes its ISP and thus the addresses assigned to it. Even if most of the addressing is handled by DHCP, changing the address scheme is going to have an impact on operations.

Addressing stability can be achieved by:

- Keeping the same provider - this would depend on the reason for the change. If the cost of this provider has become too expensive this is unlikely. If the ISP is out of business it becomes impossible.
- Transfer the addresses from the old provider to the new one - There is little motivation for an ISP to do you a favor for not doing business with them.
- Get your own autonomous system number - this can be too expensive for smaller organizations.
- NAT - this is the only one on the list that is in the control of IT.

There are differences between NAT66 and IPv4 NAT. Because there is no shortage of addresses most organizations will be given a /48 network that can be translated into another /48 network. This allows for a one to one translation, no need for port forwarding. This is a good thing because port forwarding is more complicated in IPv6. In fact, NAT66 will actually just be the rewriting of the prefix on the address.

Example

If your current IPv6 address is

```
2001:db8:cafe::/48
```

you could change it to

```
2001:db8:fea7::/48
```

There is an exception to the one to one translation. NAT66 cannot translate internal networks that contain 0xffff in bits 49 through 63 - this is due to the way checksums are calculated in TCP/IP: they use the one's-complement representation of numbers which assigns the value zero to both 0x0000 and 0xffff.

How FortiOS differentiates sessions when NATing

The basics of NAT are fairly simple. Many private addresses get translated into a smaller number of public addresses, often just one. The trick is how the FortiGate keeps track of the return traffic because the web server, or what ever device that was out on the Internet is going to be sending traffic back not to the private address behind the FortiGate but to the IP address of the interface on the public side of the FortiGate.

The way this is done is by making each session unique. Most of the attributes that are available in the network packets cannot be changed without changing where the packet will go but because the source port has to be changed anyway in case two computer on the network used the same source port this is a useful way of making each listing of network attributes a unique combination. As a packet goes through the NAT process FortiOS assigns different source ports for each of the internally initiated sessions and keeping track of which port was used for each device in a database until the session has ended. It then becomes a matter of how the port number is selected.

In a very simple example of an environment using NAT, we will use a fictitious university with a rather large student population. So large in fact that they use a subnet of `10.0.0.0/8` as their subnet for workstation IP addresses. All of these private IP addresses are NATed out a single IP address. To keep the number of numeric values in this example from getting to a confusing level, we'll just use "u.u.u.1" to refer to the public IP address of the University and the IP address of the web server on the Internet will be "w.w.w.1".

Student A (IP address `10.1.1.56`) sends an HTML request to a web server on the Internet with the IP address `w.w.w.1`. The applicable networking information in the packet breaks down as follows:

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	<code>10.1.1.56</code>	<code>u.u.u.1</code>
Destination IP address or dst-ip:	<code>w.w.w.1</code>	<code>w.w.w.1</code>
Source port or src-port:	10000	46372
Destination port or dst-port	80	80

The source IP address is now that of the public facing interface of the FortiGate and source port number is an unused TCP port number on the FortiGate chosen by the FortiGate. Of these variable the only one the that FortiGate can really change and still have the packet reach the correct destination, in both directions, is the source port number.

There are a few methods of assigning the port number. First we'll look at the methods that are or have been used in the industry but aren't used by Fortinet.

Global pool

This method of differentiation focuses on the attribute of the source port number. In this approach a single pool of potential port numbers is set aside for the purposes of NAT. As a pool number is assigned, it is removed from the pool so that two sessions from different computers can not using the same port number. Once the session is over and no longer in use by the computer, the port number is put back into the pool where it can be assigned again.

Example global pool:

	Hexidecimal	Decimal
Start or range	0x7000	28672

	Hexidecimal	Decimal
End end of range	0xF000	61440
Possible ports in range	215	32768

This is a simple approach to implement and is good if the number of connections is unlikely to reach the pool size. It would be okay for home use, but our example is for a university using 10.1.1.0/8 as a subnet. That means 16,777,214 possible IP addresses; more than this method can handle.

Fortinet does not use this method.

Global per protocol

This method uses the attributes source port number and type of protocol to differentiate between sessions. This approach is a variation of the first one. An additional piece of information is referred to in the packet that describes the protocol. For instance UDP or TCP. This could effectively double the number of potential addresses to NAT.

Example:

Here are two possible packets that would be considered different by the FortiGate so that any responses from the web server would make it back to their correct original sender.

From Student A

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	10000	46372
Destination port or dst-port	80	80

From Student B

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	udp	udp
Source port or src-port:	26785	46372
Destination port or dst-port	80	80

Even though the source port is the same, because the protocol is different they are considered to be from different sessions and different computers.

The drawback is that it would depend on the protocols being used be evenly distributed between TCP and UDP. Even if this was the case the number would only double; reaching an upper limit of 65,536 possible connections. That number is still far short of the possible more than 16 million for an IP subnet with an eight bit subnet mask like the one in our example.

Fortinet does not use this method.

Per NAT IP pool

This approach adds on to the previous one by adding another variable. In this case that variable is the IP addresses on the public side of the FortiGate. By having a pool of IP addresses to assign as the source IP address when NATing, the same number that was potentially available for the Global per protocol method can be multiplied by the number of external IP addresses in the pool. If you can assign a second IP address to the pool, you can double the potential number of sessions.

Example:

In this example it will be assumed that the FortiGate has 2 IP addresses that it can use. This could happen either by using two ISPs, or by having a pool of IP addresses assigned to a single interface. For simplicity will refer to these IP public IP addresses as `u.u.u.1` and `u.u.u.2`.

Here are two possible packets that would be considered different by the FortiGate so that any responses from the web server would make it back to their correct original sender.

From Student A

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	10000	46372
Destination port or dst-port	80	80

From Student B

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.2
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp

Attribute	Original Packet	Packet after NATing
Source port or src-port:	26785	46372
Destination port or dst-port	80	80

In this example we even made the protocol the same. After the NATing process all of the variables are the same except the source address. This is still going to make it back to the original sender.

The drawback is that if you have only one IP address for the purposes of NATing this method does not gain you anything over the last method. Or if you do have multiple IP addresses to use it will still take quite a few to reach the 16 million possible that the subnet is capable of handling.

Fortinet does not use this method.

Per NAT IP, destination IP, port, and protocol

This is the approach that FortiOS uses.

It uses all of the differentiation point of the previous methods, NAT IP, port number and protocol, but the additional information point of the destination IP is also used. So now the network information points in the packet that the FortiGate keeps in its database to differentiate between sessions is:

- Public IP address of the FortiGate assigned by NATing
- Protocol of the traffic
- Source port assigned by the FortiGate
- Destination IP address of the packet

The last one is an especially good way to differentiate because as a theoretical number, the upper limit on that is the numbers of Public IP addresses on the whole of the Internet. Chances are that while a large number of session from inside the University will be going to a small group of sites such as Google, Youtube, Facebook and some others it is unlikely that they will all be going to them at the same time.

Example:

In this example it will be assumed that the FortiGate has only one IP address. Two possible packets will be described. The only difference in the attributes recorded will be the destination of the HTML request. These packets are still considered to be from different sessions and any responses will make it back to the correct computer.

From Student A

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp

Attribute	Original Packet	Packet after NATing
Source port or src-port:	10000	46372
Destination port or dst-port	80	80

From Student B

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.1
Destination IP address or dst-ip:	w.w.w.2	w.w.w.2
Protocol	tcp	tcp
Source port or src-port:	26785	46372
Destination port or dst-port	80	80

The reason that these attributes are used to determine differentiation between traffic is based on how the indexes for the sessions are recorded in the database. When a TCP connection is made through a FortiGate unit, a session is created and two indexes are created for the session. The FortiGate unit uses these indexes to guide matching traffic to the session.

This following could be the session record for the TCP connection in the first example.

Attribute	Outgoing Traffic	Returning Traffic
Source IP address	10.78.33.97 (internal address)	w.w.w.1
Destination address	w.w.w.1	u.u.u.1
Protocol	tcp	tcp
Source port	10000 (from original computer) 46372 (assigned by NAT)	80
Destination port	80	46372 (FortiGate assigned port)

Using the FortiGate's approach for session differentiation, FortiOS only has to ensure that the assigned port, along with the other four attributes is a unique combination to identify the session. So for example, if Student A simultaneously makes a HTTP(port 80) connection and a HTTPS(port 443) connection the same web server this would create another session and the index in the reply direction would be:

Attribute	Outgoing Traffic	Returning Traffic
Source IP address	10.78.33.97 (internal address)	w.w.w.1
Destination address	w.w.w.1	u.u.u.1
Protocol	tcp	tcp
Source port	10000 (from original computer) 46372 (assigned by NAT)	443
Destination port	443	46372 (FortiGate assigned port)

These two sessions are different and acceptable because of the different source port numbers on the returning traffic or the destination port depending on the direction of the traffic.

Calculations for possible session numbers

The result of using these four attributes instead of just the one that was originally used is a large increase in the number of possible unique combinations. For those who love math, the maximum number of simultaneous connections that can be supported is:

$$N \times R \times P \times D \times Dp$$

where:

- **N** is the number of NAT IP addresses
- **R** is the port range,
- **P** is the number of protocols,
- **D** is the number of unique destination IP addresses
- **Dp** the number of unique destination ports.

As a rough example let's do some basic calculations

- **N** - In our existing example we have already stated that there is only one public IP address that is being used by NAT. Realistically, for a university this number would likely be larger, but we're keeping it simple.

$$N = 1$$

R - The port range for our example has already been describe and we will keep it the same.

$$R = 32768$$

P - While there are a few protocols that are involved in Internet traffic we will limit this calculation just to TCP traffic.

$$P = 1$$

D - As mentioned before the number of unique destination addresses is growing larger every day, so figuring out the upper limit of that number would be difficult to say the least. Instead we will make the assumption that most of the university students, do to their shared interest and similar demographic will concentrate most of their web browsing to the same sites; sites such as YouTube, Facebook, Google, Twitter, Instagram, Wikipedia etc. This is

not even taking into account the fact that many of these popular sites use load balancing and multiple IP addresses. As an arbitrary number let's use the number 25.

D = 25

Dp - To keep things simple it is tempting to limit the destination port to port 80, the one that many associate with web browsing, but this would not be realistic. the use of HTTPS, port 443 is on the rise. There is also email, DNS, FTP, NTP and a number of other background services that we use without thinking too closely about. Let's keep it small and say ten of them.

Dp = 10

The math on this very conservative calculation is:

$1 \times 32768 \times 1 \times 25 \times 10 = 8,192,000$ possible NAT sessions

When you take into account that the chances of everybody being online at the same time, going only to one of those 25 sites and not millions of others, and using only TCP not UDP or any of the other protocols, it starts to look like this method may provide enough potential unique sessions even for a subnet as large as the one described.

IP pools

IP Pools are a mechanism that allow sessions leaving the FortiGate Firewall to use NAT. An IP pool defines a single IP address or a range of IP addresses to be used as the source address for the duration of the session. These assigned addresses will be used instead of the IP address assigned to that FortiGate interface.

When using IP pools for NATing, there is a limitation that must be taken into account. In order for communication to be successful in both directions, it is normal for the source address in the packet header assigned by the NAT process to be an address that is associated with the interface that the traffic is going through. For example, if traffic is going out an interface with the IP address 172.16.100.1, packets would be NATed so that the source IP address would be 172.16.100.1. This way the returning traffic will be directed to the same interface on the same FortiGate that the traffic left from. Even if the packets are assigned a source address that is associated with another interface on the same FortiGate this can cause issues with asymmetrical routing. It is possible to configure the NATed source IP address to be different than the IP address of the interface but you have to make sure that the routing rules of the surrounding network devices take this unorthodox approach into consideration.

There are 4 types of IP Pools that can be configured on the FortiGate firewall:

- One-to-One - in this case the only internal address used by the external address is the internal address that it is mapped to.
- Overload - this is the default setting. Internal addresses other than the one designated in the policy can use this address for the purposes of NAT.
- Fixed Port Range - rather than a single address to be used, there is a range of addresses that can be used as the NAT address. These addresses are randomly assigned as the connections are made.
- Port Block Allocation - this setting is used to allocate a block of port numbers for IP pool users. Two variables will also have to be set. The block size can be set from 64 to 4096 and as the name implies describes the number of ports in one block of port numbers. The number of blocks per user determines how many of these blocks will be assigned. This number can range from 1 to 128.

Be careful when calculating the values of the variables. The maximum number of ports that are available on an address is 65,536. If you chose the maximum value for both variables you will get a number far in excess of the available port numbers.

$$4096 \times 128 = 524,288$$

One of the more common examples is when you have an email server behind your FortiGate firewall and the range of IP addresses assigned to you by your ISP is more than one. If an organization is assigned multiple IP addresses it is normally considered a best practice to assign a specific address other than the one used for the Firewall to the mail server. However, when normal NAT is used the address assigned to the firewall is also assigned to any outbound sessions. Anti-spam services match the source IP address of mail traffic that they receive to the MX record on DNS servers as an indicator for spam. If there is a mismatch the mail may not get through so there is a need to make sure that the NATed address assigned matches the MX record.

You can also use the Central NAT table as a way to configure IP pools.

Source IP address and IP pool address matching when using a range

When the source addresses are translated to an IP pool that is a range of addresses, one of the following three cases may occur:

Scenario 1:

The number of source addresses equals that of IP pool addresses

In this case, the FortiGate unit always matches the IP addressed one to one.

If you enable fixed port in such a case, the FortiGate unit preserves the original source port. This may cause conflicts if more than one security policy uses the same IP pool, or the same IP addresses are used in more than one IP pool.

Scenario 2:

The number of source addresses is more than that of IP pool addresses

In this case, the FortiGate unit translates IP addresses using a wrap-around mechanism. If you enable fixed port in such a case, the FortiGate unit preserves the original source port. But conflicts may occur since users may have different sessions using the same TCP 5 tuples.

Scenario 3:

The number of source addresses is fewer than that of IP pool addresses

In this case, some of the IP pool addresses are used and the rest of them are not be used.

ARP replies

If a FortiGate firewall interface IP address overlaps with one or more IP pool address ranges, the interface responds to ARP requests for all of the IP addresses in the overlapping IP pools. For example, consider a FortiGate unit with the following IP addresses for the port1 and port2 interfaces:

- port1 IP address: 1.1.1.1/255.255.255.0 (range is 1.1.1.0-1.1.1.255)
- port2 IP address: 2.2.2.2/255.255.255.0 (range is 2.2.2.0-2.2.2.255)

And the following IP pools:

- IP_pool_1: 1.1.1.10-1.1.1.20
- IP_pool_2: 2.2.2.10-2.2.2.20
- IP_pool_3: 2.2.2.30-2.2.2.40

The port1 interface overlap IP range with IP_pool_1 is:

$(1.1.1.0-1.1.1.255) \text{ and } (1.1.1.10-1.1.1.20) = 1.1.1.10-1.1.1.20$

The port2 interface overlap IP range with IP_pool_2 is:

$(2.2.2.0-2.2.2.255) \text{ \& } (2.2.2.10-2.2.2.20) = 2.2.2.10-2.2.2.20$

The port2 interface overlap IP range with IP_pool_3 is:

$(2.2.2.0-2.2.2.255) \text{ \& } (2.2.2.30-2.2.2.40) = 2.2.2.30-2.2.2.40$

And the result is:

- The port1 interface answers ARP requests for 1.1.1.10-1.1.1.20
- The port2 interface answers ARP requests for 2.2.2.10-2.2.2.20 and for 2.2.2.30-2.2.2.40

Select Enable NAT in a security policy and then select Dynamic IP Pool. Select an IP pool to translate the source address of packets leaving the FortiGate unit to an address randomly selected from the IP pool. Whether or not the external address of an IP Pool will respond to an ARP request can be disabled. You might want to disable the ability to respond to ARP requests so that these address cannot be used as a way into your network or show up on a port scan.

IP pools and zones

Because IP pools are associated with individual interfaces IP pools cannot be set up for a zone. IP pools are connected to individual interfaces.

Fixed port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

However, enabling the use of a fixed port means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy. The firewall randomly selects an IP address from the IP pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the IP pool.

Match-VIP

The match-vip feature allows the FortiGate unit to log virtual IP traffic that gets implicitly dropped. This feature eliminates the need to create two policies for virtual IPs; one that allows the virtual IP, and the other to get proper log entry for DROP rules.

For example, you have a virtual IP security policy and enabled the match-vip feature; the virtual IP traffic that is not matched by the policy is now caught.

The match-vip feature is available only in the CLI. By default, the feature is disabled.

Services and TCP ports

There are a number of different services and protocols in use on the Internet. The most commonly known is HTTP which is used by web servers to transmit requests and responses for unencrypted web pages. These services are set up to listen for requests on a numbered port. These services and protocols can use any port from 1 to 65,535. To keep things simple for everyone a large number of the more commonly used services started using a standardized list of ports. For instance, though it is not required, by default, most web servers listen for HTTP requests on port 80 and by default, web browsers will send HTTP traffic to port 80. If you wish to use another port such as 8080 you would put “:8080” at the end of the URL to indicate that you want the browser to use 8080 instead of the default port.

Example

Default URL for HTTP traffic when the web server is listening on the standard HTTP port:

`http://fortinet.com`

URL to the same address when the web server is listening for HTTP traffic on port 8080

`http://fortinet.com:8080`

Services represent typical traffic types and application packets that pass through the FortiGate unit. Firewall services define one or more protocols and port numbers associated with each service. Security policies use service definitions to match session types. You can organize related services into service groups to simplify your security policy list.

Many well-known traffic types have been predefined on the FortiGate unit. If there is a service that does not appear on the list you can create a service or edit an existing one. You need to know the ports, IP addresses or protocols of that particular service or application uses, to create a service.

Best Practices

While you can edit a predefined service it is best to leave those ones alone and create a new service and name it something similar such as the same service name with a descriptive identifier appended.

Based on the previous example, instead of the name “HTTP” you could name the service “HTTP8080” or use the application that is using that port, “HTTP-Application”.

Protocol types

One of the fundamental aspects of a service is the type of protocol that use used to define it. When a service is defined one of the following categories of protocol needs to be determined:

- TCP/UDP/SCTP
- ICMP
- ICMPv6
- IP

Depending on which of these protocol categories is choose another set of specifications will can also be defined.

Protocol Type	Related specifications
TCP/UDP/SCTP	This is the most commonly used service protocol category. Once this category has been selected the other available options to choose are an address, either IP or FQDN, and the protocol and port number. The protocol will be TCP, UDP or SCTP.
ICMP or ICMP6	When ICMP or ICMP6 is chosen the available options are the ICMP Type and its code.
IP	When IP is the chosen protocol type the addition option is the Protocol Number.

TCP/UDP/SCTP

TCP

Transmission Control Protocol (TCP) is one of the core or fundamental protocols of the Internet. It is part of the Transport Layer of the OSI Model. It is designed to provide reliable delivery of data from a program on one device on the network or Internet to another program on another device on the network or Internet. TCP achieves its reliability because it is a connection based protocol. TCP is stream-oriented. It transports streams of data reliably and in order.

TCP establishes a prior connection link between the hosts before sending data. This is often referred to as the handshake. Once the link is established the protocol uses checks to verify that the data transmitted. If an error check fails the data is retransmitted. This makes sure that the data is getting to the destination error free and in the correct order so that it can be put back together into a form that is identical to the way they were sent.

TCP is configured more for reliability than for speed and because of this TCP will likely be slower than a connectionless protocol such as UDP. This is why TCP is generally not used for real time applications such as voice communication or online gaming.

Some of the applications that use TCP are:

- World Wide Web (HTTP and HTTPS)
- Email (SMTP, POP3, IMAP4)
- Remote administration (RDP)
- File transfer (FTP)

UDP

User Datagram Protocol (UDP) like TCP is one of the core protocols of the Internet and part of the Transport Layer of the OSI Model. UDP is designed more for speed than reliability and is generally used for different applications than TCP. UDP sends messages, referred to as datagrams across the network or Internet to other hosts without establishing a prior communication link. In other words, there is no handshake.

UDP is an unreliable service as the datagrams can arrive out of order, duplicated or go missing without any mechanism to verify them. UDP works on the assumption that any error checking is done by the application or is not necessary for the function of the application. This way it avoids the overhead that is required to verify the integrity of the data.

This lack of overhead improves the speed of the data transfer and is why UDP is often used by applications that are time sensitive in nature. UDP's stateless nature is also great for applications that answer a large number of small queries from a large number of clients.

Common uses for UDP are:

- Domain Name Resolution (DNS)
- Time (NTP)
- Streaming media (RTSP, RTP and RTCP)
- Telephone of the Internet (VoIP)
- File Transfer (TFTP)
- Logging (SNMP)
- Online games (GTP and OGP)

SCTP

Stream Control Transmission Protocol (SCTP) is part of the Transport Layer of the OSI Model just like TCP and UDP and provides some of the features of both of those protocols. It is message or datagram orientated like UDP but it also ensures reliable sequential transport of data with congestion control like TCP.

SCTP provides the following services:

- Acknowledged error-free non-duplicated transfer of user data
- Data fragmentation to conform to discovered path MTU size
- Sequenced delivery of user messages within multiple streams, with an option for order-of-arrival delivery of individual user messages
- Optional bundling of multiple user messages into a single SCTP packet
- Network-level fault tolerance through supporting of multi-homing at either or both ends of an association
- Congestion avoidance behavior and resistance to flooding and masquerade attacks

SCTP uses multi-streaming to transport its messages which means that there can be several independent streams of messages traveling in parallel between the points of the transmission. The data is sent out in larger chunks of data than is used by TCP just like UDP but the messages include a sequence number within each message in the same way that TCP does so that the data can be reassembled at the other end of the transmission in the correct sequence without the data having to arrive in the correct sequence.

SCTP is effective as the transport protocol for applications that require monitoring and session-loss detection. For such applications, the SCTP path and session failure detection mechanisms actively monitor the connectivity of the session. SCTP differs from TCP in having multi-homing capabilities at either or both ends and several streams within a connection, typically referred to as an association. A TCP stream represents a sequence of bytes; an SCTP stream represents a sequence of messages.

Some common applications of SCTP include supporting transmission of the following protocols over IP networks:

- SCTP is important in 3G and 4G/LTE networks (for example, HomeNodeB = FemtoCells)
- SS7 over IP (for example, for 3G mobile networks)
- SCTP is also defined and used for SIP over SCTP and H.248 over SCTP
- Transport of Public Switched Telephone Network (PSTN) signaling messages over IP networks.

SCTP is a much newer protocol. It was defined by the IETF Signaling Transport (SIGTRAN) working group in 2000. It was introduced by RFC 3286 and more fully define by RFC 4960.

The FortiGate firewall can apply security policies to SCTP sessions in the same way as TCP and UDP sessions. You can create security policies that accept or deny SCTP traffic by setting the service to “ALL”. FortiOS does not include pre-defined SCTP services. To configure security policies for traffic with specific SCTP source or destination ports you must create custom firewall services for SCTP.

FortiGate units route SCTP traffic in the same way as TCP and UDP traffic. You can configure policy routes specifically for routing SCTP traffic by setting the protocol number to 132. SCTP policy routes can route SCTP traffic according to the destination port of the traffic if you add a port range to the policy route.

You can configure a FortiGate unit to perform stateful inspection of different types of SCTP traffic by creating custom SCTP services and defining the port numbers or port ranges used by those services. FortiGate units support SCTP over IPv4. The FortiGate unit performs the following checks on SCTP packets:

- Source and Destination Port and Verification Tag.
- Chunk Type, Chunk Flags and Chunk Length
- Verify that association exists
- Sequence of Chunk Types (INIT, INIT ACK, etc)
- Timer checking
- Four way handshake checking
- Heartbeat mechanism
- Protection against INIT/ACK flood DoS attacks, and long-INIT flooding
- Protection against association hijacking

FortiOS also supports SCTP sessions over IPsec VPN tunnels, as well as full traffic and event logging for SCTP sessions.

Protocol port values

The source and destination ports for TCP/UDP/SCTP services are important to get correct. If they are reversed the service will not work. The destination port(s) are the ones that refer to the ports that the computer will be listening on. These are the port numbers that most people are familiar with when they associate a port number to a protocol. In most cases the source port will be one that is randomly assigned by the computer that is not being already used by another service.

Most people associate HTTP with port 80. This means that a web-server will be listening on port 80 for any http requests being sent to the computer. The computer that is sending the request can use any port that is not already assigned to another service or communication session. There are 65,535 ports that it can randomly assign, but because the ports from 1 to 1024 are normally used for listening for incoming communications it is usually not in that range. It is unless there is a specific instance when you know that a communication will be coming from a predefined source port it is best practice to set the source port range from 1 to 65,535.

ICMP

The Internet Control Message Protocol (ICMP) is a protocol layered onto the Internet Protocol Suite to provide error reporting flow control and first-hop gateway redirection. It is normally used by the operating systems of networked computers to send connectivity status query, response and error messages. It is assigned protocol number 1. There is a separate version of the protocol for both IPv4 and for IPv6. It is not designed to be absolutely reliable like TCP.

ICMP is not typically used for transporting data or for end-user network applications with the exception of some diagnostic utilities such as ping and traceroute.

ICMP messages are sent in several situations, for example:

- when a datagram cannot reach its destination,
- time exceeded messages
- redirect messages
- when the gateway does not have the buffering capacity to forward a datagram
- when the gateway can direct the host to send traffic on a shorter route.

Some of the specific ICMP message types are:

- ICMP_ECHO
- ICMP_TIMESTAMP
- ICMP_INFO_REQUEST
- ICMP_ADDRESS

For ICMP error messages, only those reporting an error for an existing session can pass through the firewall. The security policy will allow traffic to be routed, forwarded or denied. If allowed, the ICMP packets will start a new session. Only ICMP error messages of a corresponding security policy is available will be sent back to the source. Otherwise, the packet is dropped. That is, only ICMP packets for a corresponding security policy can traverse the FortiGate unit.

ICMP types and codes

ICMP has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

ICMP types and codes

Type Number	Type Name	Optional Code(s)
0	Echo Reply	
1	Unassigned	
2	Unassigned	

Type Number	Type Name	Optional Code(s)
3	Destination Unreachable	0 Net Unreachable
		1 Host Unreachable
		2 Protocol Unreachable
		3 Port Unreachable
		4 Fragmentation Needed and Don't Fragment was Set
		5 Source Route Failed
		6 Destination Network Unknown
		7 Destination Host Unknown
		8 Source Host Isolated
		9 Communication with Destination Network is Administratively Prohibited
		10 Communication with Destination Host is Administratively Prohibited
		11 Destination Network Unreachable for Type of Service
		12 Destination Host Unreachable for Type of Service
		13 Communication Administratively Prohibited
		14 Host Precedence Violation
		15 Precedence cutoff in effect
4	Source Quench	
5	Redirect	0 Redirect Datagram for the Network (or subnet)
		1 Redirect Datagram for the Host
		2 Redirect Datagram for the Type of Service and Network
		3 Redirect Datagram for the Type of Service and Host
6	Alternate Host Address	
7	Unassigned	

Type Number	Type Name	Optional Code(s)
8	Echo	
9	Router Advertisement	
10	Router Selection	
11	Time Exceeded	0 Time to Live exceeded in Transit 1 Fragment Reassembly Time Exceeded
12	Parameter Problem	0 Pointer indicates the error 1 Missing a Required Option 2 Bad Length
13	Timestamp	
14	Timestamp Reply	
15	Information Request	
16	Information Reply	
17	Address Mask Request	
18	Address Mask Reply	
19	Reserved (for Security)	
20 - 29	Reserved (for Robustness Experiment)	
30	Traceroute	
31	Datagram Conversion Error	
32	Mobile Host Redirect	

Type Number	Type Name	Optional Code(s)
33	IPv6 Where-Are-You	
34	IPv6 I-Am-Here	
35	Mobile Registration	
36	Mobile Registration Reply	
37	Domain Name Request	
38	Domain Name Reply	
39	SKIP	
40	Photuris	
41 - 255	Reserved	

log-invalid-packet

The `log-invalid-packet` CLI setting is one that is intended to log invalid ICMP packets. The exact definition being:

If the FortiGate unit receives an ICMP error packet that contains an embedded `IP(A,B) | TCP(C,D)` header, then if FortiOS can locate the `A:C -> B:D` session it checks to make sure that the sequence number in the TCP header is within the range recorded in the session. If the sequence number is not in range then the ICMP packet is dropped.

When this field is enabled, the FortiGate also log messages that are not ICMP error packets.

Types of logs covered by log-invalid-packet

- Invalid ICMP
 - If ICMP error message verification (see "check-reset-range") is enabled
- Invalid DNS packets
 - DNS packets that contain requests for non-existing domains
- `iprope` check failed
- reverse path check fail
- denied and broadcast traffic
- no session matched

Some other examples of messages that are not errors that will be logged, based on [RFC792](#):

Type 3 messages correspond to "Destination Unreachable Message"

- Type 3, Code 1 = host unreachable
- Type 3, Code 3 = port unreachable

Type 11 messages correspond to "Time Exceeded Message"

- Type 11, Code 0 = time to live exceeded in transit

ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in [RFC 4443](#).

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.

ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).

ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

1. Destination Unreachable
2. Time Exceeded
3. Packet Too Big
4. Parameter Problems

Information messages are divided into three groups:

1. Diagnostic messages
2. Neighbor Discovery messages
3. Messages for the management of multicast groups.

ICMPv6 types and codes

ICMPv6 has a number of messages that are identified by the "Type" field. Some of these types have assigned "Code" fields as well. The table below shows the different types of ICMP Types with their associated codes if

there are any.

Type codes 0 – 127 are error messages and type codes 128 – 255 are for information messages.

ICMPv6 types and codes

Type Number	Type Name	Code
0	Reserved	0 - no route to destination
		1 - communication with destination administratively prohibited
		2 - beyond scope of source address
		3 - address unreachable
		4 - port unreachable
		5 - source address failed ingress/egress policy
		6 - reject route to destination
		7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit
		1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered
		1 - unrecognized Next Header type encountered
		2 - unrecognized IPv6 option encountered
100	Private Experimentation	
101	Private Experimentation	
102 - 126	Unassigned	
127	Reserved for expansion if ICMPv6 error messages	

Type Number	Type Name	Code
128	Echo Request	
129	Echo Replay	
130	Multicast Listener Query	
131	Multicast Listener Report	
132	Multicast Listener Done	
133	Router Solicitation	
134	Router Advertisement	
135	Neighbor Solicitation	
136	Neighbor Advertisement	
137	Redirect Message	
138	Router Renumbering	0 - Router Renumbering Command
		1 - Router Renumbering Result

IP

Internet Protocol (IP) is the primary part of the Network Layer of the OSI Model that is responsible for routing traffic across network boundaries. It is the protocol that is responsible for addressing. IPv4 is probable the version that most people are familiar with and it has been around since 1974. IPv6 is its current successor and due to a

shortage of available IPv4 addresses compared to the explosive increase in the number of devices that use IP addresses, IPv6 is rapidly increasing in use.

When IP is chosen as the protocol type the available option to further specify the protocol is the protocol number. This is used to narrow down which protocol within the Internet Protocol Suite and provide a more granular control.

Protocol number

IP is responsible for more than the address that it is most commonly associated with and there are a number of associated protocols that make up the Network Layer. While there are not 256 of them, the field that identifies them is a numeric value between 0 and 256.

In the Internet Protocol version 4 (IPv4) [RFC791] there is a field called "Protocol" to identify the next level protocol. This is an 8 bit field. In Internet Protocol version 6 (IPv6) [RFC2460], this field is called the "Next Header" field.

Protocol numbers

#	Protocol	Protocol's Full Name
0	HOPOPT	IPv6 Hop-by-Hop Option
1	ICMP	Internet Control Message Protocol
2	IGMP	Internet Group Management
3	GGP	Gateway-to-Gateway

VPN policies

At one point, if you wanted to have secure digital communications between 2 points a private network would be created. This network would only allow the people that were intended to get the communications on it. This is very straightforward if the 2 points are in the same room or even in the same building. It can all be done physically. If you are supposed to be on the secure network

VPNs are an answer to one of today's biggest concerns, how to make digital communications secure between to points that must communicate over the Internet which anybody can have access to.

There are two types of VPNs supported by FortiOS, SSL and IPsec. They are differentiated by the security protocol suites that are used to secure the traffic. These are both described in more detail in the VPN section, but the IPsec VPN can be configured as an **Action** with a firewall policy.

IPsec policies

IPsec policies allow IPsec VPN traffic access to the internal network from a remote location. These policies include authentication information that authenticates users and user group or groups. These policies specify the following:

- the FortiGate firewall interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- the FortiGate firewall interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- optional: a schedule that restricts when the VPN can operate, and services (or types of data) that can be sent.

For a route-based (interface mode) VPN, you do not configure an IPsec security policy. Instead, you configure two regular ACCEPT security policies, one for each direction of communication, with the IPsec virtual interface as the source or destination interface, as appropriate.

DSRI

The Disable Server Response Inspection (DSRI) options is available for configuration in the CLI. This is used to assist performance when only URL filtering is being used. This allows the system to ignore the HTTP server responses. The setting is configured to be disabled by default.

CLI syntax for changing the status of the DSRI setting

In IPv4 or IPv6 firewall policies

```
config firewall policy|policy6
  edit 0
    set dsri enable|disable
  end
```

In IPv4 or IPv6 interface policies

```
config firewall interface-policy|interface-policy6
  edit 0
    set dsri enable|disable
  end
```

When using the sniffer

```
config firewall sniffer
edit 0
set dsri enable|disable
end
```

Interface policies

Interface policies are implemented before the “security” policies and are only flow based. They are configured in the CLI.

This feature allows you to attach a set of IPS policies with the interface instead of the forwarding path, so packets can be delivered to IPS before entering firewall. This feature is used for following IPS deployments:

- One-Arm: by defining interface policies with IPS and DoS anomaly checks and enabling sniff-mode on the interface, the interface can be used for one-arm IDS;
- IPv6 IPS: IPS inspection can be enabled through interface IPv6 policy. Only IPS signature scan is supported in FortiOS 4.0. IPv6 DoS protection is not supported;
- Scan traffics that destined to FortiGate;
- Scan and log traffics that are silently dropped or flooded by Firewall or Multicast traffic.

IPS sensors can be assigned to an interface policy. Both incoming and outgoing packets are inspected by IPS sensor (signature).

Here is an example of an interface policy,

show full-configuration

```
config firewall interface-policy
edit 1
set status enable
set comments 'test interface policy #1'
set logtraffic utm
set interface "port9"
set srcaddr "all"
set dstaddr "all"
set service "ALL"
set application-list-status disable
set ips-sensor-status disable
set dsri disable
set av-profile-status enable
set av-profile "default"
set webfilter-profile-status disable
set spamfilter-profile-status disable
set dlp-sensor-status disable
set scan-botnet-connections disable
next
end
```

DoS protection

Denial of Service (DoS) policies are primarily used to apply DoS anomaly checks to network traffic based on the FortiGate interface it is entering as well as the source and destination addresses. DoS checks are a traffic anomaly detection feature to identify network traffic that does not fit known or common traffic patterns and

behavior. A common example of anomalous traffic is the denial of service attack. A denial of service occurs when an attacking system starts an abnormally large number of sessions with a target system. The large number of sessions slows down or disables the target system, so that legitimate users can no longer use it.

DoS policies are similar to firewall policies except that instead of defining the way traffic is allowed to flow, they keep track of certain traffic patterns and attributes and will stop traffic displaying those attributes. Further, DoS policies affect only incoming traffic on a single interface. You can further limit a DoS policy by source address, destination address, and service.

DoS configurations have been changed a couple of times in the past. In FortiOS 4.0, DoS protection is moved to the interface policy, so when it is enabled, it is the first thing checked when a packet enters FortiGate. Because of this early detection, DoS policies are a very efficient defense that uses few resources. Denial of service attacks, for example, are detected and its packets dropped before requiring security policy look-ups, antivirus scans, and other protective but resource-intensive operations.

A DoS policy examines network traffic arriving at an interface for anomalous patterns usually indicating an attack. This does not mean that all anomalies experience by the firewall are the result of an intentional attack.

Because an improperly configured DoS anomaly check can interfere with network traffic, no DoS checks are preconfigured on a factory default FortiGate unit. You must create your own before they will take effect. Thresholds for newly created sensors are preset with recommended values that you can adjust to meet the needs of your network.

To create a Denial of Service policy determine if it needs to be an IPv4 or IPv6 policy, then go to:

Policy & Objects > IPv4 DoS Policy for IPv4.

Policy & Objects > IPv6 DoS Policy for IPv6.

The **Enable SSH Deep Scan** feature is enabled by default when creating a new SSL/SSH Inspection profile. There are situations where this feature can cause issues so be sure that you would like it enabled before applying it.

Settings used in configuring DoS

Incoming interface

The interface to which this security policy applies. It will be the that the traffic is coming into the firewall on.

Source address

This will be the address that the traffic is coming from and must be a address listed in the Address section of the Firewall Objects. This can include the predefined “all” address which covers any address coming in on any interface. Multiple addresses or address groups can be chosen

Destination address

This will be the address that the traffic is addressed to. In this case it must be an address that is associated with the firewall itself. For instance it could be one of the interface address of the firewall, a secondary IP address or the interface address assigned to a Virtual IP address. Just like with the Source Address this address must be already configured before being used in the DoS policy. Multiple addresses, virtual IPs or virtual IP groups can be chosen.

Service

While the Service field allows for the use of the ALL service some administrators prefer to optimize the resources of the firewall and only check on the services that will be answered on an interface. Multiple services or service groups can be chosen.

Anomalies

The anomalies can not be configured by the user. They are predefined sensors set up for specific patterns of anomalous traffic

The anomalies that have been predefined for use in the DoS Policies are:

Anomaly Name	Description	Recommended Threshold
tcp_syn_flood	If the SYN packet rate of new TCP connections, including retransmission, to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
tcp_port_scan	If the SYN packet rate of new TCP connections, including retransmission, from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second.
tcp_src_session	If the number of concurrent TCP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
tcp_dst_session	If the number of concurrent TCP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_flood	If the UDP traffic to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_scan	If the number of UDP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_src_session	If the number of concurrent UDP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_dst_session	If the number of concurrent UDP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.

Anomaly Name	Description	Recommended Threshold
icmp_flood	If the number of ICMP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	250 packets per second.
icmp_sweep	If the number of ICMP packets originating from one source IP address exceeds the configured threshold value, the action is executed.	100 packets per second.
icmp_src_session	If the number of concurrent ICMP connections from one source IP address exceeds the configured threshold value, the action is executed.	300 concurrent sessions
icmp_dst_session	If the number of concurrent ICMP connections to one destination IP address exceeds the configured threshold value, the action is executed.	3000 concurrent sessions
ip_src_session	If the number of concurrent IP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
ip_dst_session	If the number of concurrent IP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
sctp_flood	If the number of SCTP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second
sctp_scan	If the number of SCTP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second
sctp_src_session	If the number of concurrent SCTP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions
sctp_dst_session	If the number of concurrent SCTP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions

Status

The status field is enabled to enable the sensor for the associated anomaly. In terms of actions performed there is no difference between disabling a sensor and having the action as "Pass" but by disabling sensors that are not being used for blocking or logging you can save some resources of the firewall that can be better used elsewhere.

Logging

Regardless of whether the traffic is blocked or passed through the anomalous traffic will be logged.

Pass

Allows the anomalous traffic to pass through unimpeded.

Block

For Thresholds based on the number of concurrent sessions blocking the anomaly will not allow more than the number of concurrent sessions set as the threshold.

For rate based thresholds where the threshold is measured in packets per second, the Action setting “Block” prevents the overwhelming of the firewall by anomalous traffic in one of 2 ways. Setting which of those 2 ways will be issued is determined in the CLI.

- continuous - blocks packets once an anomaly is detected. This overrides individual anomaly settings.
- periodical - allows matching anomalous traffic up to the rate set by the threshold.

If the period for a particular anomaly is 60 seconds, such as those where the threshold is measured in concurrent sessions, after the 60 second timer has expired, the number of allowed packets that match the anomaly criteria is reset to zero. This means that if you allow 10 sessions through before blocking, after the 60 seconds is up, another 10 will be allowed. The attrition of sessions from expiration should keep the allowed sessions from reaching the maximum.

To set the type of block action for the rate based anomaly sensors:

```
config ips global
    set anomaly-mode continuous
    set anomaly-mode periodical
end
```

Threshold

The threshold can be either in terms of concurrent session or in packets per second depending on which sensor is being referred to.

Quarantine

The quarantine feature is found in the CLI. This setting is used to block any further traffic from a source address that is now considered to be a malicious actor or a source of traffic dangerous to the network. Not only is no more traffic accepted for the duration of the quarantine through the DoS policy but the source IP address of the traffic is added to the banned source ip list. This list is kept in the kernel and used by

- Antivirus
- Data Leak Prevention (DLP)
- Denial of Service (DoS)
- Intrusion Prevention System (IPS)

Any policies that use any of these features will block traffic from the attacker's IP address.

Syntax

```
config firewall {DoS-policy|DoS-policy6}
    edit <policyid>
        set quarantine {none|attacker}
        set quarantine-exipiry {string}
```

```

    set quarantine-log {enable|disable}
end

```

Option	Description
quarantine	Quarantine method. <ul style="list-style-type: none"> <code>none</code> - Quarantine is disabled. <code>attacker</code> - Block all traffic sent from the attacker's IP address. The quarantined IP address is also added to the banned ip list. The destination address is not affected.
quarantine-expiry	Duration of quarantine The format is <code>###d##h##m</code> , ranging from 1 minute to 364 days, 23 hours, and 59 minutes starting from now. The default is <code>0d0h5m</code> . Requires quarantine set to <code>attacker</code> .
quarantine-log	Enables or disables the logging of quarantine events.

One-Arm IDS

Interface-based policy only defines what and how IPS functions are applied to the packets transmitted by the interface. It works no matter if the port is used in a forwarding path or used as an One-Arm device.

To enable One-Arm IDS, the user should first enable sniff-mode on the interface,

```

config system interface
    edit port2
        set ips-sniffer-mode enable
    next
end

```

Once sniff-mode is turned on, both incoming and outgoing packets will be dropped after IPS inspections. The port can be connected to a hub or a switch's SPAN port. Any packet picked up by the interface will still follow the interface policy so different IPS and DoS anomaly checks can be applied.

IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create a normal IPS sensor and assign it to the IPv6 interface policy.

```

config firewall interface-policy6
    edit 1
        set interface "port1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set service6 "ANY"
        set ips-sensor-status enable
        set ips-sensor "all_default"
    next
end

```

Traffic destined to the FortiGate unit

IPS enabled in firewall policies can only inspect the traffic pass through FortiGate unit, not the traffic destined to FortiGate unit. Enabling IPS in interface-policy allows IPS to pick up any packet on the interface so it is able to inspect attacks targeting FGT.

Dropped, flooded, broadcast, multicast and L2 packets

In many evaluation or certification tests, FortiGate firewall is often required to log any packets dropped by the firewall. In most of cases, these packets are of invalid headers so firewall just drops them silently. It is natural to forward all these packets to IPS first so FortiGate firewall is able to generate logs for invalid packets.

Flooded, broadcast and multicast traffics do not reach any of services in the forwarding path. They can be inspected by the interface policy as long as they match the addresses defined. Potentially, L2 packets can also be sent to IPS for inspection through interface-policy, but it is not enabled in FortiOS 4.0.

GUI and CLI

Now in FortiGate, there are two places that IPS can be enabled, in a firewall policy and in an interface policy. In the firewall policy implementation, IPS sensor can be configured in both CLI and GUI. When adding an IPS sensor to an interface policy it must be done through the CLI. There is no GUI input window for the “Interface Policy”. There is however, a DoS Policy section in the GUI.

Local-In policies

On the FortiGate unit, there are a number of protocols and traffic that is specific to the internal workings of FortiOS. For many of these traffic sources, you can identify a specific port/IP address for this self-originating traffic. The following traffic can be configured to a specific port/IP address:

- SNMP
- Syslog
- alert email
- FortiManager connection IP
- FortiGuard services
- FortiAnalyzer logging
- NTP
- DNS
- Authorization requests such as RADIUS
- FSSO

Security policies control the flow of traffic through the FortiGate unit. The FortiGate unit also includes the option of controlling internal traffic, that is, management traffic.

Each interface includes an allow access configuration to allow management access for specific protocols. Local policies are set up automatically to allow all users all access. Local-in policies takes this a step further, to enable or restrict the user with that access. This also extends beyond the allow access selection.

Local-in policies are configured in the CLI with the commands:

```
config firewall local-in-policy
  edit <policy_number>
    set intf <source_interface>
    set srcaddr <source_address>
```

```

    set dstaddr <destination_address>
    set action {accept | deny}
    set service <service name>
    set schedule <schedule_name>
    set comments <string>
end

```

For example, you can configure a local-in policy so that only administrators can access the FortiGate unit on weekends from a specific management computer at 192.168.21.12, represented by the address object `mgmt-comp1`, using SSH on port 3 (192.168.21.77 represented by the address object `FG-port3`) using the Weekend schedule which defines the time the of access.

```

config firewall local-in-policy
edit <l>
    set intf port3
    set srcaddr mgmt-comp1
    set dstaddr FG-port3
    set action accept
    set service SSH
    set schedule Weekend
end

```

You can also disable a policy should there be a requirement to turn off a policy for troubleshooting or other purpose. To disable a policy enter the commands:

```

config firewall local-in-policy
edit <policy_number>
    set status disable
end

```

Use the same commands with a status of enable to use the policy again.

It is also an option to dedicate the interface as HA management interface by using the setting:

```
set ha-mgmt-intf-only enable
```

Local-in policies are also supported for IPv6 by entering the command:

```
config firewall local-in-policy6.
```

While there is a section under **Policy & Objects** for viewing the existing **Local In Policy** configuration, policies cannot be created or edited here in the GUI. The Local In policies can only be created or edited in the CLI.

Security policy 0

Any security policy that is automatically added by the FortiGate unit has a policy ID number of zero (0). The most common reasons the FortiGate unit creates this policy is:

- The IPsec policy for FortiAnalyzer (and FortiManager version 3.0) is automatically added when an IPsec connection to the FortiAnalyzer unit or FortiManager is enabled.
- The policy to allow FortiGuard servers to be automatically added has a policy ID number of zero.
- The (default) drop rule that is the last rule in the policy and that is automatically added has a policy ID number of zero.
- When a network zone is defined within a VDOM, the intra-zone traffic set to allow or block is managed by policy 0 if it is not processed by a configured security policy.

This policy can appear in logs but will never appear in the security policy list, and therefore, can never be repositioned in the list.

When viewing the FortiGate firewall logs, you may find a log field entry indicating `policyid=0`. The following log message example indicates the log field `policyid=0` in bold.

```
2008-10-06 00:13:49 log_id=0022013001 type=traffic subtype=violation pri=warning
vd=root SN=179089 duration=0 user=N/A group=N/A rule=0 policyid=0 proto=17
service=137/udp app_type=N/A status=deny src=10.181.77.73 srcname=10.181.77.73
dst=10.128.1.161 dstname=10.128.1.161 src_int=N/A dst_int="Internal" sent=0 rcvd=0
src_port=137 dst_port=137 vpn=N/A tran_ip=0.0.0.0 tran_port=0
```

DNS traffic in NGFW policy-mode

FortiOS has an option to enable the creation of an implicit policy to allow DNS traffic.

Certain Application Control profiles may not work properly if DNS traffic is not allowed. Enabling the `implicit-allow-dns` option adds an implicit policy to allow the DNS traffic. This policy is situated in the policy sequence just above the implicit deny policy. Since this is a `config system settings` command, this option can be enabled per VDOM.

CLI

```
config system settings
set implicit-allow-dns {enable|disable}
end
```

Deny policies

Deny security policies deny traffic that is coming into the network. The FortiGate unit automatically blocks traffic that is associated with a deny security policy.

Deny security policies are usually configured when you need to restrict specific traffic, for example, SSH traffic. Deny security policies can also help when you want to block a service, such as DNS, but allow a specific DNS server.

Accept policies

Accept security policies accept traffic that is coming into the network. These policies allow traffic through the FortiGate unit, where the packets are scanned, translated if NAT is enabled, and then sent out to its destination.

Accept security policies are the most common security policies that are created in FortiOS. These security policies are basic policies, such as allowing Internet access, as well as complex policies, such as IPsec VPN.

Fixed port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

From the CLI you can enable `fixedport` when configuring a security policy for NAT policies to prevent source port translation.

```
config firewall policy
edit <policy-id>
...
```

```
set fixedport enable
...
end
```

However, enabling fixedport means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy. The firewall randomly selects an IP address from the IP pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the pool.

Endpoint security

Endpoint security enforces the use of the FortiClient End Point Security (FortiClient and FortiClient Lite) application on your network. It can also allow or deny endpoints access to the network based on the application installed on them.

By applying endpoint security to a security policy, you can enforce this type of security on your network. FortiClient enforcement can check that the endpoint is running the most recent version of the FortiClient application, that the antivirus signatures are up-to-date, and that the firewall is enabled. An endpoint is usually often a single PC with a single IP address being used to access network services through a FortiGate unit.

With endpoint security enabled on a policy, traffic that attempts to pass through, the FortiGate unit runs compliance checks on the originating host on the source interface. Non-compliant endpoints are blocked. If someone is browsing the web, the endpoints are redirected to a web portal which explains the non-compliance and provides a link to download the FortiClient application installer. The web portal is already installed on the FortiGate unit, as a replacement message, which you can modify if required.

Endpoint Security requires that all hosts using the security policy have the FortiClient Endpoint Security agent installed. Currently, FortiClient Endpoint Security is available for Microsoft Windows 2000 and later only.

For more information about endpoint security, see the Security Profiles chapter in the FortiOS Handbook.

Traffic logging

When you enable logging on a security policy, the FortiGate unit records the scanning process activity that occurs, as well as whether the FortiGate unit allowed or denied the traffic according to the rules stated in the security policy. This information can provide insight into whether a security policy is working properly, as well as if there needs to be any modifications to the security policy, such as adding traffic shaping for better traffic performance.

Depending on what the FortiGate unit has in the way of resources, there may be advantages in optimizing the amount of logging taking places. This is why in each policy you are given 3 options for the logging:

- **Disable Log Allowed Traffic** - Does not record any log messages about traffic accepted by this policy.

If you enable Log Allowed Traffic, the following two options are available:

- **Security Events** - This records only log messages relating to security events caused by traffic accepted by this policy.
- **All Sessions** - This records all log messages relating to all of the traffic accepted by this policy.

Depending on the model, if the Log all Sessions option is selected there may be 2 additional options. These options are normally available in the GUI on the higher end models such as the FortiGate 600C or larger.

- **Generate Logs when Session Starts**
- **Capture Packets**

You can also use the CLI to enter the following command to write a log message when a session starts:

```
config firewall policy
  edit <policy-index>
    set logtraffic-start
  end
```

Traffic is logged in the traffic log file and provides detailed information that you may not think you need, but do. For example, the traffic log can have information about an application used (web: HTTP.Image), and whether or not the packet was SNAT or DNAT translated. The following is an example of a traffic log message.

```
2011-04-13
05:23:47
log_id=4
type=traffic
subtype=other
pri=notice
vd=root
status="start"
src="10.41.101.20"
srcname="10.41.101.20"
src_port=58115
dst="172.20.120.100"
dstname="172.20.120.100"
dst_country="N/A"
dst_port=137
tran_ip="N/A"
tran_port=0
tran_sip="10.31.101.41"
tran_sport=58115
service="137/udp"
proto=17
app_type="N/A"
duration=0
rule=1
policyid=1
sent=0
rcvd=0
shaper_drop_sent=0
shaper_drop_rcvd=0
perip_drop=0
src_int="internal"
dst_int="wan1"
SN=97404 app="N/A"
app_cat="N/A"
carrier_ep="N/A"
```

If you want to know more about logging, see the Logging and Reporting chapter in the FortiOS Handbook. If you want to know more about traffic log messages, see the FortiGate Log Message Reference.

IPv6

Internet Protocol version 6 (IPv6) will succeed IPv4 as the standard networking protocol of the Internet. IPv6 provides a number of advances over IPv4 but the primary reason for its replacing IPv4 is its limitation in addresses. IPv4 uses 32 bit addresses which means there is a theoretical limit of 2 to the power of 32. The IPv6 address scheme is based on a 128 bit address or a theoretical limit of 2 to the power of 128.

IPv6 addressing

Possible addresses:

- IPv4 = 4,294,967,296 (over 4 billion)
- IPv6 = 340,282,366,920,938,463,463,374,607,431,768,211,456 (over 340 undecillion - We had to look that term up. We didn't know what a number followed by 36 digits was either)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,000,000,000 devices with an IP address. That's 42 quintillion devices.

There is little likelihood that you will ever need to worry about these numbers as any kind of serious limitation in addressing but they do give an idea of the scope of the difference in the available addressing.

IPv6 address syntax

Aside from the difference of possible addresses there is also the different formatting of the addresses that will need to be addressed.

A computer would view an IPv4 address as a 32 bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period “.”

Example:

```
10101100.00010000.11111110.00000001
```

To make number more user friendly for humans we translate this into decimal, again 4 octets separated by a period “.” which works out to:

```
172.16.254.1
```

A computer would view an IPv6 address as a 128 bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon “:”

```
1000000000000001:0000110110111000:101011000001000:1111111000000001:0000000000000000  
0:0000000000000000:0000000000000000:0000000000000000
```

To make number a little more user friendly for humans we translate this into hexadecimal, again 8 octets separated by a colon “:” which works out to:

```
8001:0DB8:AC10:FE01:0000:0000:0000:0000:
```

Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, this address can be shortened further to:

8001:0DB8:AC10:FE01:0:0:0:0

or

8001:0DB8:AC10:FE01::

IPv6 packet structure

Each IPv6 packet consists of a mandatory fixed header and optional extension headers, and carries a payload, which is typically either a datagram and/or Transport Layer information. The payload could also contain data for the Internet Layer or Link Layer. Unlike IPv4, IPv6 packets aren't fragmented by routers, requiring hosts to implement Maximum Transmission Unit (MTU) Path Discovery for MTUs larger than the smallest MTU (which is 1280 octets).

Jumbograms and jumbo payloads

In IPv6, packets which exceed the MTU of the underlying network are labeled jumbograms, which consist of a jumbo payload. A jumbogram typically exceeds the IP MTU size limit of 65,535 octets, and provides the jumbo payload option, which can allow up to nearly 4GiB of payload data, as defined in [RFC 2675](#). When the MTU is determined to be too large, the receiving host sends a 'Packet too Big' ICMPv6 type 2 message to the sender.

Fragmentation and reassembly

As noted, packets that are too large for the MTU require hosts to perform MTU Path Discovery to determine the maximum size of packets to send. Packets that are too large require a 'Fragment' extension header, to divide the payload into segments that are 8 octets in length (except for the last fragment, which is smaller). Packets are reassembled according to the extension header and the fragment offset.

Benefits of IPv6

In addition to the expanded number of addresses, some of the other benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local and global address space

IPv6 in FortiOS

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary differences are the use of IPv6 format for addresses and fewer address types for IPv6. There is also no need for NAT if the FortiGate firewall is the interface between IPv6 networks. If the subnets attached to the FortiGate firewall are IPv6 and IPv4 NAT can be configured between the 2 different formats. This will involve either configuring a dual stack routing or IPv4 tunneling configuration. The reason for this is simple. NAT was developed primarily for the purpose of extending the number of usable IPv4 addresses. IPv6's addressing allows for enough available addresses so the NAT is no longer necessary.

When configuring IPv6 in FortiOS, you can create a dual stack route or IPv4-IPv6 tunnel. A dual stack routing configuration implements dual IP layers, supporting both IPv4 and IPv6, in both hosts and routers. An IPv4-IPv6 tunnel is essentially similar, creating a tunnel that encapsulates IPv6 packets within IPv4 headers that carry these IPv6 packets over IPv4 tunnels. The FortiGate unit can also be easily integrated into an IPv6 network. Connecting the FortiGate unit to an IPv6 network is exactly the same as connecting it to an IPv4 network, the only difference is that you are using IPv6 addresses.

By default the IPv6 settings are not displayed in the Web-based Manager. It is just a matter of enabling the display of these feature to use them through the web interface. To enable them just go to **System > Feature Select** and select **IPv6**. Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features:

- Static routing
- Policy Routing
- Packet and network sniffing
- Dynamic routing (RIPv6, BGP4+, and OSPFv3)
- IPsec VPN
- DNS
- DHCP
- SSL VPN
- Network interface addressing
- Security Profiles protection
- Routing access lists and prefix lists
- NAT/Route and transparent mode
- NAT 64 and NAT 66
- IPv6 tunnel over IPv4 and IPv4 tunnel over IPv6
- Logging and reporting
- Security policies
- SNMP
- Authentication
- Virtual IPs and groups
- IPv6 over SCTP
- IPv6-specific troubleshooting, such as ping6

IPv6 features

In order to configure IPv6 features using the web-based manager, IPv6 must be enabled using Feature Select. Go to **System > Config > Features**, enable IPv6, and click **Apply**.

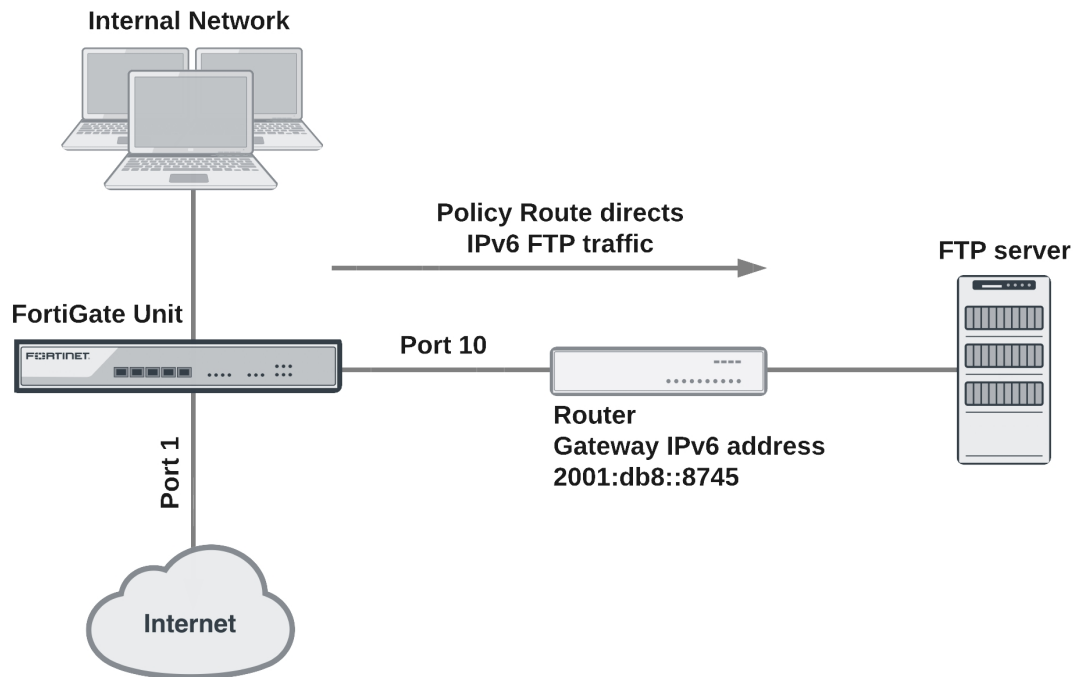

The following IPv6 features are available from the FortiOS web manager:

IPv6 policies

IPv6 security policies are created both for an IPv6 network and a transitional network. A transitional network is a network that is transitioning over to IPv6 but must still have access to the Internet or must connect over an IPv4 network.

These policies allow for this specific type of traffic to travel between the IPv6 and IPv4 networks. The IPv6 options for creating these policies is hidden by default. You must enable this feature under **System > Config > Features**.

IPv6 policy route

IPv6 policy routing

IPv6 policy routing functions in the same way as IPv4 policy routing. To add an IPv6 policy route, go to **Network > Policy Routes** and select **Create New > IPv6 Policy Route**.

Adding an IPv6 Policy route

New Routing Policy

If incoming traffic matches:

Protocol TCP UDP SCTP ANY Specify 0

Incoming interface Ednet (SSID: Student-net)

Source address / mask ::/0

Destination address / mask ::/0

Type of Service Bit Pattern 0x00 Bit Mask 0x00

Then:

Outgoing interface Click to set...

Gateway Address ::

Comments 0/255

OK Cancel

You can also use the following command to add IPv6 policy routes:

```
config router policy6
  edit 0
    set input-device <interface>
    set src <ipv6_ip>
    set dst <ipv6_ip>
    set protocol <0-255>
    set gateway <ipv6_ip>
    set output-device <interface>
    set tos <bit_pattern>
    set tos-mask <bit_mask>
  end
```

IPv6 security policies

IPv6 security policies support all the features supported by IPv4 security policies:

- Policy types and subtypes.
- NAT support including using the destination interface IP address, fixed port, and dynamic IP pools.
- All security features (antivirus, web filtering, application control, IPS, email filtering, DLP, VoIP, and ICAP).
- All traffic shaping options, including: shared traffic shaping, reverse shared traffic shaping, and per-IP traffic shaping.
- All user and device authentication options.

IPv6 explicit web proxy

You can use the explicit web proxy for IPv6 traffic. To do this you need to:

- Enable the IPv6 explicit web proxy from the CLI.
- Enable the explicit web proxy for one or more FortiGate interfaces. These interfaces also need IPv6 addresses.
- Add IPv6 web proxy security policies to allow the explicit web proxy to accept IPv6 traffic.

Use the following steps to set up a FortiGate unit to accept IPv6 traffic for the explicit web proxy at the Internal interface and forward IPv6 explicit proxy traffic out the wan1 interface to the Internet.

1. Enter the following CLI command to enable the IPv6 explicit web proxy:

```
config web-proxy explicit
  set status enable
  set ipv6-status enable
end
```

2. Go to **Network > Interfaces** and edit the **internal** interface, select **Enable Explicit Web Proxy** and select **OK**.
3. Go to **Policy & Objects > Proxy Policy** and select **Create New** to add an IPv6 explicit web proxy security policy with the following settings shown.

This IPv6 explicit web proxy policy allows traffic from all IPv6 IP addresses to connect through the explicit web proxy and through the wan1 interface to any IPv6 addresses that are accessible from the wan1 interface.

If you have enabled both the IPv4 and the IPv6 explicit web proxy, you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

Example IPv6 Explicit Web Proxy security policy

New Policy	
Explicit Proxy Type	<input checked="" type="radio"/> Web <input type="radio"/> FTP
Enabled On	internal ?
Source Address	<input type="text" value="all"/> +
Outgoing Interface	<input type="text" value="wan1"/> +
Destination Address	<input type="text" value="all"/> +
Schedule	<input type="text" value="always"/>
Action	<input checked="" type="text" value="ACCEPT"/>

Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy using only one IPv6 address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require users to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 HTTP proxy, use the following command:

```
config web-proxy explicit
  set incoming-ipv6 2001:db8:0:2::30
```

```
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config http-proxy explicit
  set outgoing-ip6 2001:db8:0:2::50
end
```

VIP64

VIP64 policies can be used to configure static NAT virtual IPv6 address for IPv4 addresses. VIP64 can be configured from the CLI using the following commands:

```
config firewall vip64
  edit <zname_str>
    set arp-reply {enable | disable}
    set color <color_int>
    set comment <comment_str>
    set extip <address_ipv6>[-address_ipv6]
    set extport <port_int>
    set id <id_num_str>
    set mappedip [<start_ipv4>-<end_ipv4>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <addr_str>
  end
```

VIP64 CLI Variables and Defaults

Variable	Description	Default
<zname_str>	Enter the name of this virtual IP address.	No default.
arp-reply {enable disable}	Select to respond to ARP requests for this virtual IP address.	enable
color <color_int>	Enter the number of the color to use for the group icon in the web-based manager.	0
comment <comment_str>	Enter comments relevant to the configured virtual IP.	No default.

Variable	Description	Default
<code>extip <address_ipv6>[-address_ipv6]</code>	<p>Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>To configure a dynamic virtual IP that accepts connections destined for any IP address, set <code>extip</code> to <code>::</code>.</p>	<code>::</code>
<code>extport <port_int></code>	<p>Enter the external port number that you want to map to a port number on the destination network.</p> <p>This option only appears if <code>portforward</code> is enabled.</p> <p>If <code>portforward</code> is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set <code>extport</code> to the first port number in the range. Then set <code>mappedport</code> to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the <code>extport</code> port number range.</p>	0
<code>id <id_num_str></code>	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.

Variable	Description	Default
mappedip [<start_ipv4>-<end_ipv4>]	<p>Enter the IP address or IP address range on the destination network to which the external IP address is mapped.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as a single IP address to create a one-to-many mapping.</p>	0.0.0.0
mappedport <port_int>	<p>Enter the port number on the destination network to which the external port number is mapped.</p> <p>You can also enter a port number range to forward packets to multiple ports on the destination network.</p> <p>For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.</p>	0
portforward {enable disable}	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring <code>extport</code> and <code>mappedport</code> .	disable
src-filter <addr_str>	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x:x:x:x:x:x/n). Separate addresses with spaces.	null

VIP46 policies can be used to configure static NAT virtual IPv4 address for IPv6 addresses. VIP46 can be configured from the CLI using the following commands (see the table below for variable details):

```
config firewall vip46
  edit <name_str>
    set arp-reply {enable | disable}
    set color <color_int>
    set comment <comment_str>
    set extip <address_ipv4>[-address_ipv4]
    set extport <port_int>
```

```

    set id <id_num_str>
    set mappedip [<start_ipv6>--<end_ipv6>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <add_str>
end

```

VIP46 CLI Variables and Defaults

Variable	Description	Default
<name_str>	Enter the name of this virtual IP address.	No default.
arp-reply {enable disable}	Select to respond to ARP requests for this virtual IP address.	enable
color <color_int>	Enter the number of the color to use for the group icon in the web-based manager.	0
comment <comment_str>	Enter comments relevant to the configured virtual IP.	No default.
extip <address_ipv4>[- address_ipv4]	<p>Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>To configure a dynamic virtual IP that accepts connections destined for any IP address, set <code>extip</code> to 0.0.0.0.</p>	0.0.0.0

Variable	Description	Default
<code>extport <port_int></code>	<p>Enter the external port number that you want to map to a port number on the destination network.</p> <p>This option only appears if <code>portforward</code> is enabled.</p> <p>If <code>portforward</code> is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set <code>extport</code> to the first port number in the range. Then set <code>mappedport</code> to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the <code>extport</code> port number range.</p>	0
<code>id <id_num_str></code>	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.
<code>mappedip [<start_ipv6>-<end_ipv6>]</code>	<p>Enter the IP address or IP address range on the destination network to which the external IP address is mapped.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as a single IP address to create a one-to-many mapping.</p>	::

Variable	Description	Default
<code>mappedport <port_int></code>	<p>Enter the port number on the destination network to which the external port number is mapped.</p> <p>You can also enter a port number range to forward packets to multiple ports on the destination network.</p> <p>For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.</p>	0
<code>portforward {enable disable}</code>	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring <code>extport</code> and <code>mappedport</code> .	disable
<code>src-filter <addr_str></code>	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x.x.x.x/n). Separate addresses with spaces.	null

IPv6 network address translation

NAT66, NAT64, and DNS64 are now supported for IPv6. These options provide IPv6 NAT and DNS capabilities with IPv6-IPv4 tunneling or dual stack configurations. The commands are available only in the CLI.

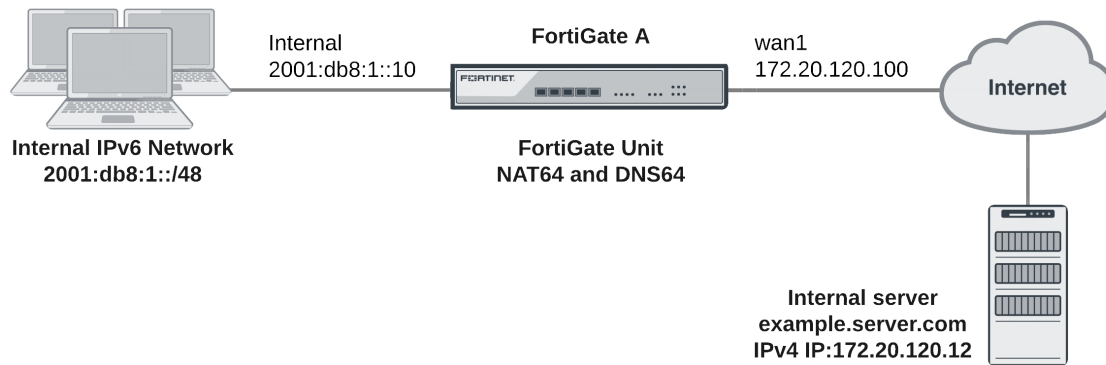

Fortinet supports all features described in [RFC 6146](#). However, for DNS64 there is no support for handling Domain Name System Security Extensions (DNSSEC). DNSSEC is for securing types of information that are provided by the DNS as used on an IP network or networks. You can find more information about DNS64 in [RFC 6147](#).

NAT64 and DNS64 (DNS proxy)

NAT64 is used to translate IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. 'DNS proxy' and 'DNS64' are interchangeable terms.

Example NAT64 configuration

With a NAT64 and DNS64 configuration in place on a FortiGate unit, clients on an IPv6 network can transparently connect to addresses on an IPv4 network. NAT64 and DNS64 perform the IPv4 to IPv6 transition, allowing clients that have already switched to IPv6 addresses to continue communicating with servers that still use IPv4 addresses.

To enable NAT64 and DNS64, use the following CLI commands:

Enable NAT64

```
config system nat64
  set status enable
end
```

Enable the DNS proxy on the IPv6 interface

```
config system dns-server
  edit internal
  end
```

In your DHCP6 configuration, configure the IPv6 interface IP address as the DNS6 server IP address. The FortiGate will proxy DNS requests to the system DNS server.

```
config system dhcp6 server
  edit 1
    set interface internal
    config ip-range
      edit 1
        set start-ip 2001:db8:1::11
        set end-ip 2001:db8:1::20
      end
    set dns-server1 2001:db8:1::10
  end
```

NAT64 policies

You can configure security policies for NAT64 using the web-based manager. For these options to appear, the feature must be enabled using **System > Feature Visibility**. You can then configure the policies under **Policy & Objects > NAT64 Policy**.

NAT64 policies and can also be configured from the CLI using the following command:

```
config firewall policy64
```

In the following section, you will configure a NAT64 policy that allows connections from an internal IPv6 network to an external IPv4 network.

Configuring NAT64 to allow a host on the IPv6 network to connect to the Internet server

In this example, the Internal IPv6 network address is 2001:db8:1::/48 and the external IPv4 network address is 172.20.120.0/24. NAT64 is configured to allow a user on the internal network to connect to the server at IPv4 address 172.20.120.12. In this configuration, sessions exiting the wan1 interface must have their source address changed to an IPv4 address in the range 172.20.120.200 to 172.20.120.210.

Enter the following command to enable NAT64:

```
config system nat64
  set status enable
end
```

Enabling NAT64 with the `config system nat64` command means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

By using the `nat64-prefix` option of the `config system nat64` command to change the default nat64 prefix from the well-known prefix of 64:ff9b::/96 and setting `always-synthesize-aaaa-record` to enable (default), the DNS proxy does not check for AAAA records but rather synthesizes AAAA records.

As an alternative to the above entry, there is the optional configuration that would allow the resolution of CNAME queries.

```
config system nat64
  set status enable
  set nat64-prefix 64:ff9b::/96
  set always-synthesize-aaaa-record enable
end
```

Enter the following command to add an IPv6 firewall address for the internal network:

```
config firewall address6
  edit internal-net6
    set ip6 2001:db8:1::/48
  end
```

Enter the following command to add an IPv4 firewall address for the external network:

```
config firewall address
  edit external-net4
    set subnet 172.20.120.0/24
    set associated-interface wan1
  end
```

Enter the following command to add an IP pool containing the IPv4 address that the should become the source address of the packets exiting the wan1 interface:

```
config firewall ippool
```

```
edit exit-pool4
    set startip 172.20.120.200
    set endip 172.20.120.210
end
```

Enter the following command to add a NAT64 policy that allows connections from the internal IPv6 network to the external IPv4 network:

```
config firewall policy64
    edit 0
        set srcintf internal
        set srcaddr internal-net6
        set dstintf wan1
        set dstaddr external-net4
        set action accept
        set schedule always
        set service ANY
        set logtraffic enable
        set ippool enable
        set poolname exit-pool4
    end
```

The `srcaddr` can be any IPv6 firewall address and the `dstaddr` can be any IPv4 firewall address.

Other NAT64 policy options include `fixedport`, which can be used to prevent NAT64 from changing the destination port. You can also configure traffic shaping for NAT64 policies.

How a host on the internal IPv6 network communicates with `example.server.com` that only has IPv4 address on the Internet

1. The host on the internal network does a DNS lookup for `example.server.com` by sending a DNS query for an AAAA record for `example.server.com`.
2. The DNS query is intercepted by the FortiGate DNS proxy.
3. The DNS proxy attempts to resolve the query with a DNS server on the Internet and discovers that there are no AAAA records for `example.server.com`.
4. The previous step is skipped if `always-synthesize-aaaa-record` is enabled.
5. The DNS proxy performs an A-record query for `example.server.com` and gets back an RRSet containing a single A record with the IPv4 address `172.20.120.12`.
6. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is `64:ff9b::172.20.120.12`.
7. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address `64:ff9b::172.20.120.12`.
8. The packet is routed to the FortiGate internal interface where it is accepted by the NAT64 security policy.
9. The FortiGate unit translates the destination address of the packets from IPv6 address `64:ff9b::172.20.120.12` to IPv4 address `172.20.120.12` and translates the source address of the packets to `172.20.120.200` (or another address in the IP pool range) and forwards the packets out the `wan1` interface to the Internet.

NAT66

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as

much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy from the CLI. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy. For example, use the following command to add an IPv6 security policy that translates the source address of IPv6 packets to the address of the destination interface (similar to IPv4 source NAT):

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr internal_net
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
  end
```

It's also useful to translate one IPv6 source address to another address that is not the same as the address of the exiting interface. You can do this using IP pools. For example, enter the following command to add an IPv6 IP pool containing one IPv6 IP address:

```
config firewall ippool6
  edit example_6_pool
    set startip 2001:db8::
    set endip 2001:db8::
  end
```

Enter the following command to add an IPv6 firewall address that contains a single IPv6 IP address.

```
config firewall address6
  edit device_address
    set ip6 2001:db8::132/128
  end
```

Enter the following command to add an IPv6 security policy that accepts packets from a device with IP address 2001:db8::132 and translates the source address to 2001:db8::.

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr device_address
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
    set ippool enable
    set poolname example_6_pool
  end
```

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, enter the following command to add an IPv6 virtual IP that maps the destination address 2001:db8::dd to 2001:db8::ee.

```
config firewall vip6
  edit example-vip6
    set extip 2001:db8::dd
    set mappedip 2001:db8::ee
  end
```

Enter the following command to add an IPv6 security policy that accepts packets with a destination address 2001:db8::dd and translates that destination address to 2001:db8::ee.

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set dstaddr example-vip6
    set action accept
    set schedule always
    set service ANY
  end
```

NAT64 and NAT66 session failover

The FortiGate Clustering Protocol (FGCP) supports IPv6, NAT64, and NAT66 session failover. If session pickup is enabled, these sessions are synchronized between cluster members and, after an HA failover, the sessions will resume with only minimal interruption.

NAT46

NAT46 is used to translate IPv4 addresses to IPv6 addresses so that a client on an IPv4 network can communicate transparently with a server on an IPv6 network.

To enable NAT46, use the following CLI command:

```
config firewall vip46
```

NAT46 policies

Security policies for NAT46 can be configured from the web-based manager. For these options to appear in the web-based manager, this feature must be enabled using **System > Feature Visibility**. You can then configure the policies under **Policy & Objects > NAT46 Policy**.

NAT46 policies can also be configured from the CLI using the following command:

```
config firewall policy46
```

IPv6 tunneling

IPv6 Tunneling is the act of tunneling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than Network Address Translation (NAT) because once the packet reaches its final destination the true originating address of the sender will still be readable. The IPv6 packets are encapsulated

within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network. This type of configuration is more appropriate for those who have completely transitional over to IPv6, but need an Internet connection, which is still mostly IPv4 addresses.

The key to IPv6 tunneling is the ability of the 2 devices, whether they are a host or a network device, to be dual stack compatible. They have to be able to work with both IPv4 and IPv6 at the same time. In the process the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet. The IPv4 header is removed. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6:

Automatic tunnels	Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to.
Configured tunnels	Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

Tunnel configurations

There are a few ways in which the tunneling can be performed depending on which segment of the path between the end points of the session the encapsulation takes place.

Network Device to Network Device	Dual stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans one segment of the path taken by the IPv6 packets.
Host to Network Device	Dual stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. This type of tunnel spans the first segment of the path taken by the IPv6 packets.
Host to Host	Dual stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.
Network Device to Host	Dual stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

Use the following command to tunnel IPv6 traffic over an IPv4 network. The IPv6 interface is configured under `config system interface`. The command to do the reverse is `config system ipv6-tunnel`. These commands are not available in transparent mode.

```
config system sit-tunnel
  edit <tunnel name>
    set destination <tunnel _address>
    set interface <name>
```

```

    set ip6 <address_ipv6>
    set source <address_ipv4>
end

```

Variable	Description	Default
edit <tunnel_name>	Enter a name for the IPv6 tunnel.	No default.
destination <tunnel_address>	The destination IPv4 address for this tunnel.	0.0.0.0
interface <name>	The interface used to send and receive traffic for this tunnel.	No default.
ip6 <address_ipv6>	The IPv6 address for this tunnel.	No default.
source <address_ipv4>	The source IPv4 address for this tunnel.	0.0.0.0

Tunneling IPv6 through IPsec VPN

A variation on the tunneling IPv6 through IPv4 is using an IPsec VPN tunnel between two FortiGate devices. FortiOS supports IPv6 over IPsec. In this sort of scenario, 2 networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPsec VPN tunnel is created between the 2 FortiGate units and a tunnel is created over the IPv4 based Internet but the traffic in the tunnel is IPv6. This has the additional advantage of making the traffic secure as well.

For configuration information, see [IPv6 IPsec VPN on page 1](#).

IPv6 support for GRE tunnels

You can use IPv6 addresses can be used at both ends of a GRE tunnel in the same way as with IPv4.

The configuration is similar to how you set up the tunnel for IPv4. However, when you configure the specific tunnel, you need to set the `ip-version` option to 6. This will enable IPv6-specific options for the tunnel.

CLI

```

config system gre-tunnel
  edit <name of tunnel>
    set ip-version 6
    set remote-gw6 <IPv6 address of the remote gateway>
    set local-gw-6 <IPv6 address of the local gateway>
  end

```

SIP over IPv6

FortiOS supports Sessions Initiate Protocol (SIP) over IPv6. The SIP application-level gateway (ALG) can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown below, a SIP phone connects to the Internet through a FortiGate unit operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate unit has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.

To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

New Fortinet FortiGate IPv6 MIB fields

The following IPv6 MIB fields have been added to the Fortinet FortiGate MIB. These MIB entries can be used to display IPv6 session and policy statistics.

- IPv6 Session Counters:

```

fgSysSes6Count
fgSysSes6Rate1
fgSysSes6Rate10
fgSysSes6Rate30
fgSysSes6Rate60
  
```

- IPv6 Policy Statistics:

```

fgFwPol6StatsTable
fgFwPol6StatsEntry
FgFwPol6StatsEntry
fgFwPol6ID
fgFwPol6PktCount
fgFwPol6ByteCount
  
```

- IPv6 Session Statistics:

```

fgIp6SessStatsTable
fgIp6SessStatsEntry
FgIp6SessStatsEntry
fgIp6SessNumber
  
```

The `fgSysSesCount` and `fgSysSesRateX` MIBs report statistics for IPv4 plus IPv6 sessions combined. This behavior was not changed.

New OIDs

The following OIDs have been added:

```
FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgSystem.fgSystemInfo
.fgSysSes6Count      1.3.6.1.4.1.12356.101.4.1.15
.fgSysSesRate1       1.3.6.1.4.1.12356.101.4.1.16
.fgSysSesRate10      1.3.6.1.4.1.12356.101.4.1.17
.fgSysSesRate30      1.3.6.1.4.1.12356.101.4.1.18
.fgSysSesRate60      1.3.6.1.4.1.12356.101.4.1.19

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies.fgFwPolTables
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ID      1.3.6.1.4.1.12356.101.5.1.2.2.1.1
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6PktCount 1.3.6.1.4.1.12356.101.5.1.2.2.1.
2
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ByteCount 1.3.6.1.4.1.12356.101.5.1.2.2.1
.3

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgInetProto.fgInetProtoTables
.fgIp6SessStatsTable.fgIp6SessStatsEntry.fgIp6SessNumber 1.3.6.1.4.1.12356.101.11.2.3.1.1
```

EXAMPLE SNMP get/walk output

```
// Session6 stats excerpt from sysinfo:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.4
FORTINET-FORTIGATE-MIB::fgSysSes6Count.0 = Gauge32: 203
FORTINET-FORTIGATE-MIB::fgSysSes6Rate1.0 = Gauge32: 10 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate10.0 = Gauge32: 2 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate30.0 = Gauge32: 1 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate60.0 = Gauge32: 0 Sessions Per Second

// FwPolicy6 table:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.5.1.2.2

FORTINET-FORTIGATE-MIB::fgIp6SessNumber.1 = Counter32: 89
```

IPv6 per-IP traffic shaper

You can add any Per-IP traffic shaper to an IPv6 security policy using the following command:

```
config firewall policy6
edit 0
set per-ip-shaper "new-perip-shaper"
end
```

DHCPv6

You can use DHCP with IPv6 using the CLI. To configure DHCP, ensure IPv6 is enabled by going to **System** > **Feature Visibility** and enabling **IPv6**.

Use the CLI command

```
config system dhcp6
```

For more information on the configuration options, see the [FortiGate CLI Reference](#).

DHCP delegated mode

Downstream IPv6 interfaces can receive address assignments on delegated subnets from a DHCP server that serves an upstream interface.

DHCPv6-PD configuration

Enable DHCPv6 Prefix Delegation on upstream interface (port10):

```
config system interface
  edit "port10"
    config ipv6
      set dhcp6-prefix-delegation enable
    end
  end
```

Assign delegated prefix on downstream interface (port1). Optionally, specific delegated prefixes can be specified:

```
config system interface
  edit "port1"
    config ipv6
      set ip6-mode delegated
      set ip6-upstream-interface "port10"
      set ip6-subnet ::1:0:0:0:1/64
      set ip6-send-adv enable
      config ipv6-delegated-prefix-list
        edit 1
          set upstream-interface "port10"
          set autonomous-flag enable
          set onlink-flag enable
          set subnet 0:0:0:100::/64
        end
      end
    end
  end
```

DHCPv6 server configuration

Configuring a server that uses delegated prefix and DNS from upstream:

```
config system dhcp6 server
  edit 1
    set dns-service delegated
    set interface "wan2"
    set upstream-interface "wan1"
    set ip-mode delegated
    set subnet 0:0:0:102::/64
  end
```

DHCPv6 relay

You can use the following command to configure a FortiGate interface to relay DHCPv6 queries and responses from one network to a network with a DHCPv6 server and back. The command enables DHCPv6 relay and includes adding the IPv6 address of the DHCP server that the FortiGate unit relays DHCPv6 requests to:

```
config system interface
  edit internal
    config ipv6
      set dhcp6-relay-service enable
      set dhcp6-relay-type regular
      set dhcp6-relay-ip 2001:db8:0:2::30
    end
```

IPv6 forwarding

Policies, IPS, Application Control, flow-based antivirus, web filtering, and DLP

FortiOS fully supports flow-based inspection of IPv6 traffic. This includes full support for IPS, application control, virus scanning, and web filtering.

To add flow-based inspection to IPv6 traffic go to **Policy & Objects > IPv6 Policy** and select **Create New** to add an IPv6 Security Policy. Configure the policy to accept the traffic to be scanned. Under **Security Profiles**, select the profiles to apply to the traffic.

Obtaining IPv6 addresses from an IPv6 DHCP server

From the CLI, you can configure any FortiGate interface to get an IPv6 address from an IPv6 DHCP server. For example, to configure the wan2 interface to get an IPv6 address from an IPv6 DHCP server enter the following command:

```
config system interface
  edit wan2
    config ipv6
      set ip6-mode dhcp
    end
```

Authentication support

RADIUS

FortiOS's supports IPv6 RADIUS authentication. When configuring the FortiGate interface and the RADIUS server (under `config system interface` and `config user radius` respectively), the server IP address can be set as IPv6.

Captive portal

Captive portal supports IPv6. It works with remote RADIUS authentication and WiFi interfaces.

FSSO

FortiGate FSSO supports connecting to an FSSO agent over IPv6 and collecting and sending IPv6 details about endpoints. This is all enforced the same way as IPv4 FSSO traffic.

CLI

```
config user fsso
  edit <fsso agent name>
    set source-ip6 <IPv6 address for source>
  end
```

The source-ip6 option accepts either an IPv6 format address or a Fully Qualified Domain Name (FQDN). The FQDN can parse to an IPv6 address.

IPv6 Neighbor Discovery Proxy

This feature provides support for proxying the IPv6 Neighbor Discovery (ND) protocol to allow the forwarding of the following ICMP messages between upstream and downstream interfaces:

- Router Advertisement (RA)
- Neighbor Solicitation (NS)
- Neighbor Advertisement (NA)
- Router Solicitation (RS)
- Redirect

Normally, only one interface will receive RA traffic. This will automatically be considered the upstream interface.

The Neighbor Discovery (ND) protocol is used to discover the Link Layer address of IPv6 destinations. In IPv4, this is achieved by using ARP.

Configure ND Proxy in the CLI using the following syntax:

```
config system nd-proxy
  set status {enable|disable}
  set member <interface> <interface> [<interface>...]
end
```

Option	Description
status	Enable/disable the use of neighbor discovery proxy
member	List of interfaces using the neighbor discovery proxy

An example of a configuration can be found in the IPv6 Configuration section under [IPv6 Neighbor Discovery Proxy on page 663](#)

More information on Neighbor Discovery Proxies (ND Proxy) is available at [RFC 4389](#).

IPv6 configuration

This section contains configuration information for IPv6 on FortiOS. Attempts are made to include scenarios in each section to better assist with the configuration and to orient the information toward a particular task.

You will find information on the following:

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

To enable IPv6:

1. Go to **System > Features**.
2. Select **IPv6** and click **Apply**.

IPv6 address groups

To create IPv6 address groups from existing IPv6 addresses - web-based manager

Your company has 3 internal servers with IPv6 addresses that it would like to group together for the purposes of a number of policies.

1. Go to **Policy & Objects > Addresses** and select **Create New > Address Group**.
2. Select **IPv6 Group**, and fill out the fields with the following information:

Group Name	Web_Server_Cluster
Members	Web_Server-1
	Web_Server-2
	Web_Server-3

3. Select **OK**.

To create IPv6 address groups from existing IPv6 addresses - CLI

```
config firewall addrgrp6
  edit Web_Server_Cluster
    set member Web_Server-1 Web_Server-2 Web_Server-3
  end
```

To verify that the addresses were added correctly

1. Go to **Policy & Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. From the CLI, enter the following commands:

```
config firewall addrgrp6
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

IPv6 address ranges

You can configure IPv6 address ranges in both the GUI and the CLI.

To configure IPv6 address ranges - web-based manager:

1. Go to **Policy & Objects > Addresses**.
2. Set the **Type** to **IP Range** and enter the IPv6 addresses as shown:

To configure IPv6 address ranges - CLI:

```
config firewall address6
  edit ipv6range
    set type iprange
    set start-ip 2001:db8:0:2::30
    set end-ip 2001:db8:0:2::31
  end
```

IPv6 firewall addresses

Scenario: Mail server

You need to create an IPv6 address for the Mail Server on Port1 of your internal network. This server is on the network off of port1.

- The IP address is 2001:db8:0:2::20/128
- There should be a tag for this address being for a server.

Configuring the Example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Mail_Server
Type	Subnet

IPv6 Address	2001:db8:0:2::20/128
---------------------	----------------------

3. Select **OK**.

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
edit Mail_Server
set type ipprefix
set subnet 2001:db8:0:2::20/128
end
```

Scenario: First floor network

You need to create an IPv6 address for the subnet of the internal network off of Port1. These computers connect to port1. The network uses the IPv6 addresses: fdde:5a7d:f40b:2e9d:xxxx:xxxx:xxxx:xxxx

There should be a reference to this being the network for the 1st floor of the building.

1. Go to **Policy & Objects > Objects > Addresses**
2. Select **Create New > Address**. Select **IPv6 Address** and fill out the fields with the following information:

Name	Internal_Subnet_1
Type	Subnet / IP Range
IPv6 Address	2001:db8:0:2::/64
Comments	Network for 1st Floor

3. Select **OK**.

4. Enter the following CLI command:

```
config firewall address6
edit Internal_Subnet_1
set comment "Network for 1st Floor"
set type ipprefix
set subnet 2001:db8:0:2::/64
end
```

Scenario: Accounting team

You need to create an IPv6 address for the Accounting Team that's on the 1st Floor. These users are off of various ports of the FortiGate, but they have all been assigned addresses between 2001:db8:0:2::2000 and 2001:db8:0:2::a000

Configuring the example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Accounting_Team
Type	IP Range
Subnet / IP Range	2001:db8:0:2::2000-2001:db8:0:2::a000

3. Select **OK**.

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
edit Accounting_Team
set type iprange
set visibility enable
set start-ip 2001:db8:0:2::2000
set end-ip 2001:db8:0:2::a000
end
```

To verify that the addresses were added correctly:

1. Go to **Policy & Objects > Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address6
edit <the name of the address that you wish to verify>
Show full-configuration
```

IPv6 SSH

FortiGate supports SSH traffic through IPv6. When the proxy option is set to `ssh` in a proxy policy, IPv6 source and destination address options become available and SSH profiles can be assigned to IPv6 firewall policies.

Syntax in IPv6 firewall policy

```
config firewall policy6
edit 1
set utm-status enable
set ssh-filter-profile <example>
end
```

Syntax in proxy policy

```
config firewall proxy-policy
edit 1
set proxy ssh
set srcaddr6 "all"
set dstaddr6 "all"
end
```

Logging

When a proxy policy is being used, SSH traffic logs are generated by `wad` instead of the kernel.

ICMPv6

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node information responses is 140. The codes for a successful response is 0.

To configure ICMPv6 - web-based manager:

1. Go to **Policy & Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	diagnostic-test1
Service Type	Firewall
Show in Service List	Enabled
Category	Uncategorized
Protocol Type	ICMP6
Type	140

3. Select **OK**.
4. Enter the following CLI command:

```
config firewall service custom
edit diagnostic-test1
set protocol ICMP6
set icmp-type 140
set icmp-code 0
set visibility enable
end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Services**. Check that the services have been added to the services list and that they are correct.
2. Enter the following CLI command:

```
config firewall service custom
edit <the name of the service that you wish to verify>
show full-configuration
```

IPv6 IPsec VPN

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

To enable IPv6:

1. Go to **System > Features**.
2. Select **IPv6** and click **Apply**.

The topics in this section include:

- [Overview of IPv6 IPsec support](#)
- [Configuring IPv6 IPsec VPNs](#)
- [Site-to-site IPv6 over IPv6 VPN example](#)
- [Site-to-site IPv4 over IPv6 VPN example](#)
- [Site-to-site IPv6 over IPv4 VPN example](#)

Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can also combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	<p>The VPN gateways have IPv6 addresses.</p> <p>The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors.</p>
IPv6 over IPv4	<p>The VPN gateways have IPv4 addresses.</p> <p>The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors.</p>

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: phase 1 settings, phase 2 settings, security policies, and routing.

Phase 1 configuration

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec phase 1 configuration as IPv6 by setting `ip-version` to 6. Its default value is 4. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
edit tunnel6
set ip-version 6
set remote-gw6 0:123:4567::1234
set interface port3
set proposal 3des-md5
end
```

Phase 2 configuration

To create an IPv6 IPsec phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default “0.0.0.0/0” address for Source address and Destination address to the IPv6 value “::/0”. If needed, enter specific IPv6 addresses, address ranges or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, “::/0” for the `subnet6` address type, for example. The simplest IPv6 phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
edit tunnel6_p2
set phase1name tunnel6
set proposal 3des-md5
set src-addr-type subnet6
set dst-addr-type subnet6
end
```

Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network’s port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

To create a static route - web-based manager:

1. Go to **Network > Static Routes**.

2. Select the drop-down arrow on the **Create New** button and select **IPv6 Route**.
3. Enter the information and select **OK**.

To create a static route - CLI:

1. In the CLI, use the `router static6` command. For example, where the remote network is `fec0:0000:0000:0004::/64` and the IPsec interface is `toB`:

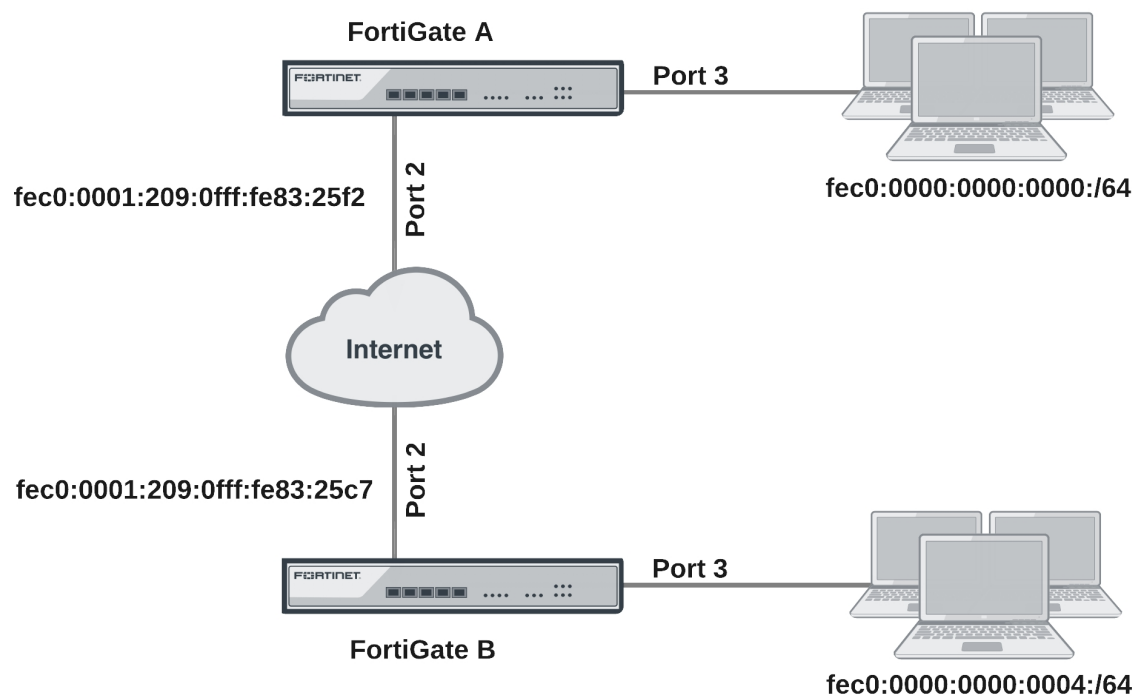

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst fec0:0000:0000:0004::/64
  next
end
```

If the VPN is IPv4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

Example IPv6-over-IPv6 VPN topology

Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0000:209:0fff:fe83:25f3/64
    end
  next
end
```

Configure FortiGate A IPsec settings

The phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to 6 and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all6
    set dstaddr all6
    set action accept
```

```

        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toB
        set dstintf port3
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    end

```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```

config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toB
        set dst fec0:0000:0000:0004::/64
    end

```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

```

config system interface
    edit port2
        config ipv6
            set ip6-address fec0::0003:209:0fff:fe83:25c7/64
        end
    next
    edit port3
        config ipv6
            set ip6-address fec0::0004:209:0fff:fe83:2569/64
        end
    end
config vpn ipsec phase1-interface
    edit toA
        set ip-version 6
        set interface port2
        set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
        set dpd enable
        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end
config vpn ipsec phase2-interface
    edit toA2

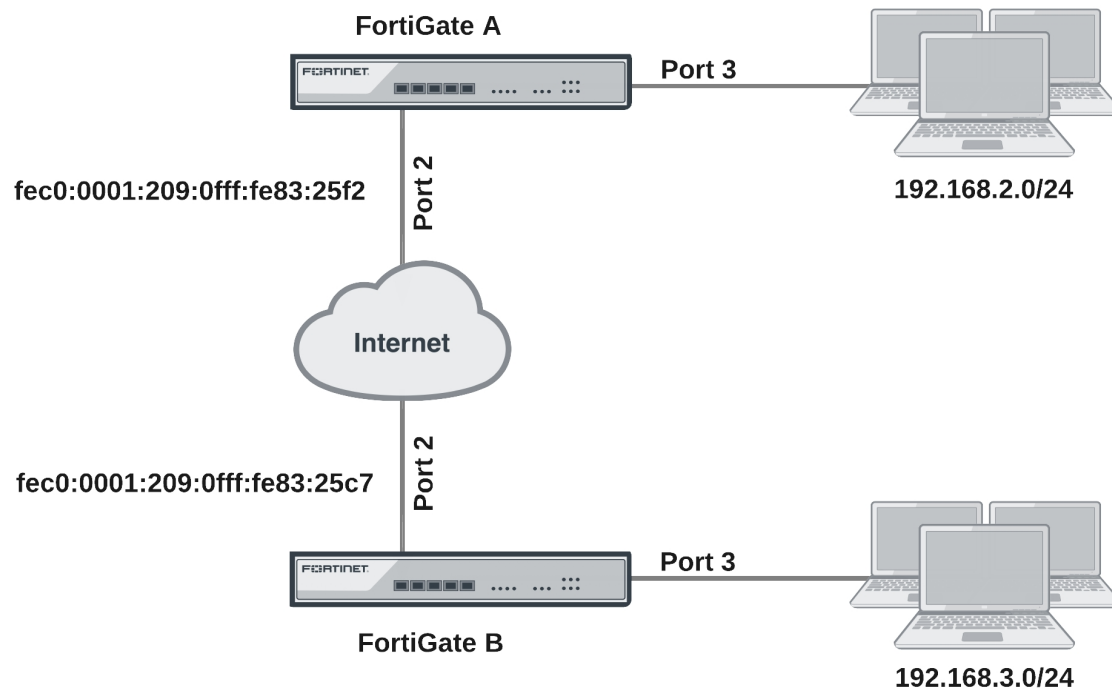

```

```
        set phase1name toA
        set proposal 3des-md5 3des-sha1
        set pfs enable
        set replay enable
        set src-addr-type subnet6
        set dst-addr-type subnet6
    end
config firewall policy6
    edit 1
        set srcintf port3
        set dstintf toA
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    end
config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toA
        set dst fec0:0000:0000:0000::/64
end
```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Example IPv4-over-IPv6 VPN topology

Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    set 192.168.2.1/24
  end
```

Configure FortiGate A IPsec settings

The phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The phase 2 configuration is the same as you would use for an IPv4 VPN. By default, phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
edit toB2
    set phaselname toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
next
edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
edit 1
    set device port2
    set dst 0::/0
next
edit 2
    set device toB
    set dst 192.168.3.0/24
end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec phase 2 configuration has

IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

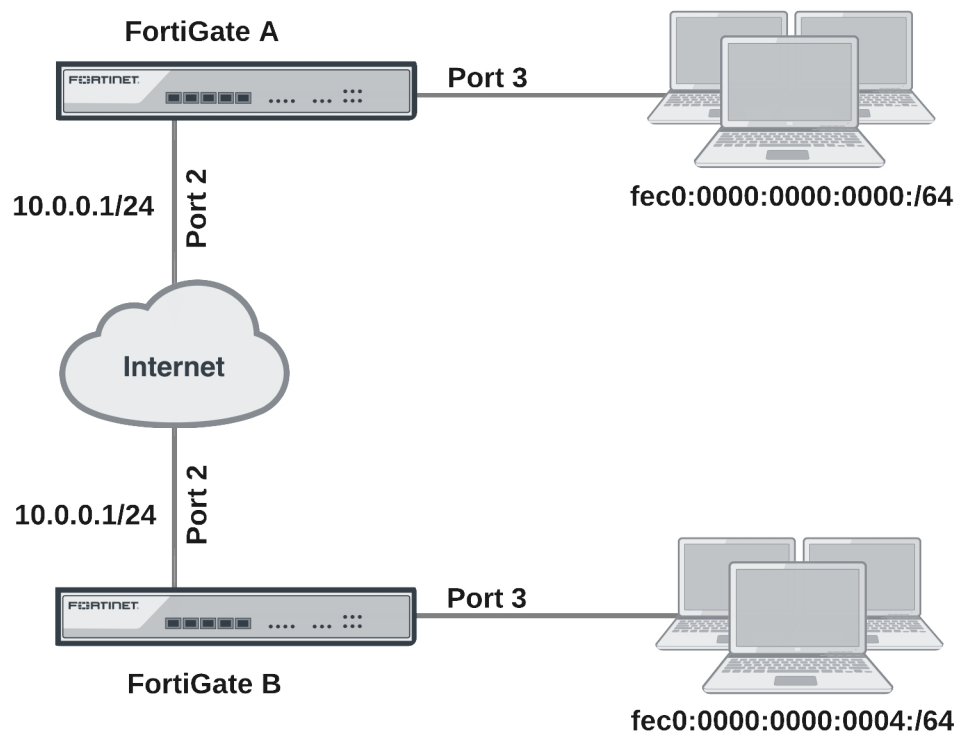

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0003:fe83:25c7/64
    end
  next
  edit port3
    set 192.168.3.1/24
  end
config vpn ipsec phase1-interface
  edit toA
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
  end
config firewall policy
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toA
    set dst 192.168.2.0/24
```

end

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Example IPv6-over-IPv4 VPN topology

Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
  edit port2
    set 10.0.0.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f3/64
    end
  end
```

Configure FortiGate A IPsec settings

The phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
  edit toB
```

```

        set interface port2
        set remote-gw 10.0.1.1
        set dpd enable
        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end

```

The phase 2 configuration uses IPv6 selectors. By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are `0.0.0.0/0` for IPv4, `::/0` for IPv6.

```

config vpn ipsec phase2-interface
    edit toB2
        set phase1name toB
        set proposal 3des-md5 3des-sha1
        set pfs enable
        set replay enable
        set src-addr-type subnet6
        set dst-addr-type subnet6
    end

```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between `port3` and the IPsec interface `toB` in each direction. Define the address `all6` using the `firewall address6` command as `::/0`.

```

config firewall policy6
    edit 1
        set srcintf port3
        set dstintf toB
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toB
        set dstintf port3
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    end

```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface `toB` using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on `port2`.

```

config router static6
    edit 1
        set device toB
        set dst fec0:0000:0000:0004::/64
    end
config router static
    edit 1

```

```
set device port2
set dst 0.0.0.0/0
set gateway 10.0.0.254
end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
  edit port2
    set 10.0.1.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
config vpn ipsec phase1-interface
  edit toA
    set interface port2
    set remote-gw 10.0.0.1
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  end
config router static6
  edit 1
    set device toA
```

```

        set dst fec0:0000:0000:0000::/64
    end
config router static
    edit 1
        set device port2
        set gateway 10.0.1.254
    end

```

TCP MSS values

TCP MSS values, which control the maximum amount of data that can be sent in a single packet, can be set for IPv6 policies (for both the sender and the receiver). You can configure TCP MSS values in IPv6 using the following CLI commands:

```

config firewall policy6
    edit <index_int>
        set tcp-mss-sender <value>
        set tcp-mss-receiver <value>
    end

```

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`.

IPv6 BGP commands include:

```

config router bgp
    set activate6 {enable | disable}
    set allowas-in6 <max_num_AS_integer>
    set allowas-in-enable6 {enable | disable}
    set as-override6 {enable | disable}
    set attribute-unchanged6 [as-path] [med] [next-hop]
    set capability-default-originate6 {enable | disable}
    set capability-graceful-restart6 {enable | disable}
    set default-originate-route-map6 <routemap_str>
    set distribute-list-in6 <access-list-name_str>
    set distribute-list-out6 <access-list-name_str>
    set filter-list-in6 <aspath-list-name_str>
    set filter-list-out6 <aspath-list-name_str>
    set maximum-prefix6 <prefix_integer>
    set maximum-prefix-threshold6 <percentage_integer>
    set maximum-prefix-warning-only6 {enable | disable}
    set next-hop-self6 {enable | disable}
    set prefix-list-in6 <prefix-list-name_str>
    set prefix-list-out6 <prefix-list-name_str>
    set remove-private-as6 {enable | disable}
    set route-map-in6 <routemap-name_str>
    set route-map-out6 <routemap-name_str>
    set route-reflector-client6 {enable | disable}
    set route-server-client6 {enable | disable}
    set send-community6 {both | disable | extended | standard}
    set soft-reconfiguration6 {enable | disable}
    set unsuppress-map6 <route-map-name_str>
config network6

```

```
config redistribute6
end
```

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

This section includes the following topics:

- [Network layout and assumptions](#)
- [Configuring the FortiGate units system information](#)
- [Configuring RIPng on FortiGate units](#)
- [Configuring other network devices](#)
- [Testing the configuration](#)
- [Debugging IPv6 on RIPng](#)

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows:

Rip example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Network topology for the IPv6 RIPng example

Assumptions

The following assumptions have been made concerning this example:

- All FortiGate units have 5.0+ firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labeled port1 and port2 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager:

1. Go to **Dashboard**.
2. For **Host name**, select **Change**.
3. Enter "Router1".
4. Go to **System > Feature Visibility**.
5. Enable **IPv6** and click **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Netmask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Netmask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router1 - CLI:

```

config system global
    set hostname Router1
    set gui-ipv6 enable
end
config system interface
    edit port1
        set alias internal
        set allowaccess https ping ssh
        set description "Internal RnD network"
        config ipv6
            set ip6-address 2002:a0b:6565::/0
        end
    end
    next
    edit port2
        set alias ISP
        set allowaccess https ping ssh
        set description "ISP and internet"
        config ipv6
            set ip6-address 2002:AC14:7865::
        end
    end
end

```

To configure system information on Router2 - web-based manager:

1. Go to **Dashboard**.
2. For **Host name**, select **Change**.
3. Enter "Router2".
4. Go to **System > Feature Visibility**.
5. Enable **IPv6** and click **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Netmask	2002:A0B:6566::/0

Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Netmask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router2 - CLI:

```

config system global
    set hostname Router2
    set gui-ipv6 enable
end
config system interface
    edit port1
        set alias internal
        set allowaccess https ping ssh
        set description "Internal RnD network"
        config ipv6
            set ip6-address 2002:a0b:6566::/0
        end
    end
    next
    edit port2
        set alias ISP
        set allowaccess https ping ssh
        set description "ISP and internet"
        config ipv6
            set ip6-address 2002:AC14:7866::
        end
    end
end

```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI:

```
config router ripng
config interface
edit port1
next
edit port2
end
config neighbor
edit 1
set interface port1
set ipv6 2002:a0b:6566::/0
next
edit 2
set interface port2
set ipv6 2002:AC14:7805::/0
end
```

To configure RIPng on Router2 - CLI:

```
config router ripng
config interface
edit port1
next
edit port2
end
config neighbor
edit 1
set interface port1
set ipv6 2002:a0b:6565::/0
next
edit 2
set interface port2
set ipv6 2002:AC14:7805::/0
end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the [FortiOS Handbook Troubleshooting](#) chapter.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (`diagnose ipv6 route list`) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

Turn on debugging in general

Set the debug level to information, a verbose reporting level

Turn on all RIP router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

IPv6 RSSO support

RADIUS Single Sign-On (RSSO) is supported in IPv6, but can only be configured in the CLI:

```
config firewall policy6
  edit <id>
    set rso enable
    set fall-through-unauthenticated enable
  end
```

IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
  edit 1
    set interface "port1"
    set srcaddr6 "all"
    set dstaddr6 "all"
    set service6 "ANY"
    set ips-sensor-status enable
    set ips-sensor "all_default"
  next
end
```

Blocking IPv6 packets by extension headers

FortiOS can now block IPv6 packets based on the extension headers, using the CLI syntax:

```
config firewall ipv6-eh-filter.
```

The following commands are now available:

- `set hop-opt {disable | enable}`: Block packets with Hop-by-Hop Options header.
- `set dest-opt {disable | enable}`: Block packets with Destination Options header.
- `set hdopt-type <integer>`: Block specific Hop-by-Hop and/or Destination Option types (maximum 7 types, each between 0 and 255).
- `set routing {disable | enable}`: Block packets with Routing header.
- `set routing-type <integer>`: Block specific Routing header types (maximum 7 types, each between 0 and 255).
- `set fragment {disable | enable}`: Block packets with Fragment header.
- `set auth {disable | enable}`: Block packets with Authentication header.
- `set no-next {disable | enable}`: Block packets with No Next header.

IPv6 denial of service policies

Denial of Service (DoS) policies can now be configured by going to **Policy & Objects > IPv6 DoS Policy**. For more information, refer to the “Interface Policies” section of the [FortiOS Handbook Firewall](#) chapter.

Configure hosts in an SNMP v1/2c community to send queries or receive traps

When you add a host to an SNMP v1/2c community you can now decide whether the FortiGate unit will accept queries from the host or whether the FortiGate unit will send traps to the host. You can also configure the host for both traps and queries. You can add up to 16 IPv4 hosts and up to 16 IPv6 hosts.

Use the following command to add two hosts to an SNMP community:

```
config system snmp community
  config hosts
    edit 1
      set interface port1
      set ip 172.20.120.1
      set host-type query
    end
  config hosts6
```

```

edit 1
    set interface port6
    set ip 2001:db8:0:2::30
    set host-type trap
end

```

IPv6 PIM sparse mode multicast routing

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with [RFC 4601](#). You can use the following command to configure IPv6 PIM sparse multicast routing.

```

config router multicast6
    set multicast-routing {enable | disable}
    config interface
        edit <interface-name>
            set hello-interval <1-65535 seconds>
            set hello-holdtime <1-65535 seconds>
        end
    config pim-sm-global
    config rp-address
        edit <index>
            set ipv6-address <ipv6-address>
        end
    end
end

```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```

diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute

```

IPv6 Neighbor Discovery Proxy

The following is an example configuration of a FortiGate using ND Proxy. Some of these configuration steps have been covered elsewhere, but are shown here to demonstrate how they all work together to achieve the desired effect.

Steps:

- Create zone for ND proxy use that includes the upstream and downstream interfaces.
- Create policies to allow ICMPv6 and DHCPv6 traffic.
- Enable ND Proxy on the interfaces.
- Enable "autoconf" on the upstream interface.

1. Add a zone including wan and lan.

It is possible to use firewall and multicast policies that don't use a zone, but using a zone simplifies the configuration, especially if you have more than two interfaces.

```

config system zone
    edit ndproxy_zone
        set interface wan lan
    end

```

On some models the "lan" interface is named "internal".

2. Add forward firewall policy and multicast policy to allow at least ICMPv6 and DHCPv6 traffic.

```
config firewall multicast-policy6
edit 0
    set srcintf ndproxy_zone
    set dstintf ndproxy_zone
    set srcaddr all
    set dstaddr all
end
```

and

```
config firewall policy6
edit 0
    set srcintf ndproxy_zone
    set dstintf ndproxy_zone
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
end
```

3. Enable ND proxy on WAN and LAN.

```
config system nd-proxy
    set status enable
    set member wan lan
end
```

4. Enable `autoconf` on the upstream interface.

RA received on the other interface(s) will be dropped.

```
config system interface
edit wan
...
config ipv6
    set autoconf enable
end
end
```

Network defense

This section describes in general terms the means by which attackers can attempt to compromise your network using attacks at the network level rather than through application vulnerabilities, and steps you can take to protect it. The goal of an attack can be as complex as gaining access to your network and the privileged information it contains, or as simple as preventing customers from accessing your web server.

Because of popular media, many people are aware of viruses and other malware as a threat against their computers and data, but some of the most costly malicious attack in history have been against networks. A 2016 study found that a single DDoS attack could cost a company over \$1.6 million. Depending on the size and type of company the areas of expense can be:

- Changes in credit and insurance ratings
- Overtime payment to employees
- Hiring new employees to increase IT staff
- PR expenses to restore a company's reputation
- Upgrading infrastructure and software
- Customer compensation

The following topics are included in this section:

- [Monitoring](#)
- [Blocking external probes](#)
- [Defending against DoS attacks](#)

Monitoring

Monitoring, in the form of logging, alert email, and SNMP, does not directly protect your network. But monitoring allows you to review the progress of an attack, whether afterwards or while in progress. How the attack unfolds may reveal weaknesses in your preparations. The packet archive and sniffer policy logs can reveal more details about the attack. Depending on the detail in your logs, you may be able to determine the attacker's location and identity.

While log information is valuable, you must balance the log information with the resources required to collect and store it.

Blocking external probes

Protection against attacks is important, but attackers often use vulnerabilities and network tools to gather information about your network to plan an attack. It is often easier to prevent an attacker from learning important details about your network than to defend against an attack designed to exploit your particular network.

Attacks are often tailored to the hardware or operating system of the target, so reconnaissance is often the first step. The IP addresses of the hosts, the open ports, and the operating systems the hosts are running is invaluable information to an attacker. Probing your network can be as simple as an attacker performing an address sweep or port scan to a more involved operation like sending TCP packets with invalid combinations of flags to see how your firewall reacts.

Address sweeps

An address sweep is a basic network scanning technique to determine which addresses in an address range have active hosts. A typical address sweep involves sending an ICMP ECHO request (a ping) to each address in an address range to attempt to get a response. A response signifies that there is a host at this address that responded to the ping. It then becomes a target for more detailed and potentially invasive attacks.

Address sweeps do not always reveal all the hosts in an address range because some systems may be configured to ignore ECHO requests and not respond, and some firewalls and gateways may be configured to prevent ECHO requests from being transmitted to the destination network. Despite this shortcoming, Address sweeps are still used because they are simple to perform with software tools that automate the process.

Use the `icmp_sweep` anomaly in a DoS policy to protect against address sweeps.

There are a number of IPS signatures to detect the use of ICMP probes that can gather information about your network. These signatures include `AddressMask`, `Traceroute`, `ICMP.Invalid.Packet.Size`, and `ICMP.Oversized.Packet`. Include ICMP protocol signatures in your IPS sensors to protect against these probes/attacks.

Port scans

Potential attackers may run a port scan on one or more of your hosts. This involves trying to establish a communication session to each port on a host. If the connection is successful, a service may be available that the attacker can exploit.

Use the DoS anomaly check for `tcp_port_scan` to limit the number of sessions (complete and incomplete) from a single source IP address to the configured threshold. If the number of sessions exceed the threshold, the configured action is taken.

Use the DoS anomaly check for `udp_scan` to limit UDP sessions in the same way.

Probes using IP traffic options

Every TCP packet has space reserved for eight flags or control bits. They are used for communicating various control messages. Although space in the packet is reserved for all eight, there are various combinations of flags that should never happen in normal network operation. For example, the SYN flag, used to initiate a session, and the FIN flag, used to end a session, should never be set in the same packet.

Attackers may create packets with these invalid combinations to test how a host will react. Various operating systems and hardware react in different ways, giving a potential attackers clues about the components of your network.

The IPS signature `TCP.Bad.Flags` detects these invalid combinations. The default action is pass though you can override the default and set it to **Block** in your IPS sensor.

Configure packet replay and TCP sequence checking

The `anti-replay` command in the CLI allows you to set the level of checking for packet replay and TCP sequence checking (or TCP Sequence (SEQ) number checking). All TCP packets contain a Sequence Number (SEQ) and an Acknowledgment Number (ACK). The TCP protocol uses these numbers for error free end-to-end communications. TCP sequence checking can also be used to validate individual packets.

FortiGate units use TCP sequence checking to make sure that a packet is part of a TCP session. By default, if a packet is received with sequence numbers that fall out of the expected range, the FortiGate unit drops the packet. This is normally a desired behavior, since it means that the packet is invalid. But in some cases you may

want to configure different levels of `anti-replay` checking if some of your network equipment uses non-RFC methods when sending packets.

Configure the anti-replay CLI command:

```
config system global
    set anti-replay {disable | loose | strict}
end
```

You can set `anti-replay` protection to the following settings:

- `disable` — No anti-replay protection.
- `loose` — Perform packet sequence checking and ICMP anti-replay checking with the following criteria:
 - The SYN, FIN, and RST bit can not appear in the same packet.
 - The FortiGate unit does not allow more than one ICMP error packet through before it receives a normal TCP or UDP packet.
 - If the FortiGate unit receives an RST packet, and `check-reset-range` is set to `strict`, the FortiGate unit checks to determine if its sequence number in the RST is within the un-ACKed data and drops the packet if the sequence number is incorrect.
- `strict` — Performs all of the loose checking but for each new session also checks to determine if the TCP sequence number in a SYN packet has been calculated correctly and started from the correct value for each new session. Strict anti-replay checking can also help prevent SYN flooding.

If any packet fails a check it is dropped.

The anti-replay setting only affects non-accelerated traffic.

Configure ICMP error message verification

Enable ICMP error message verification to ensure an attacker can not send an invalid ICMP error message.

```
config system global
    check-reset-range {disable | strict}
end
```

- `disable` — the FortiGate unit does not validate ICMP error messages.
- `strict` — enable ICMP error message checking.

If the FortiGate unit receives an ICMP error packet that contains an embedded IP(A,B) | TCP(C,D) header, then if FortiOS can locate the A:C->B:D session it checks to make sure that the sequence number in the TCP header is within the range recorded in the session. If the sequence number is not in range then the ICMP packet is dropped. Strict checking also affects how the anti-replay option checks packets.

Protocol header checking

Select the level of checking performed on protocol headers.

```
config system global
    check-protocol-header {loose | strict}
end
```

- `loose` — the FortiGate unit performs basic header checking to verify that a packet is part of a session and should be processed. Basic header checking includes verifying that the layer-4 protocol header length, the IP header length, the IP version, the IP checksum, IP options are correct, etc.

- `strict` — the FortiGate unit does the same checking as above plus it verifies that ESP packets have the correct sequence number, SPI, and data length.

If the packet fails header checking it is dropped by the FortiGate unit.

Evasion techniques

Attackers employ a wide range of tactics to try to disguise their techniques. If an attacker disguises a known attack in such a way that it is not recognized, the attack will evade your security and possibly succeed. FortiGate security recognizes a wide variety of evasion techniques and normalizes data traffic before inspecting it.

Packet fragmentation

Information sent across local networks and the Internet is encapsulated in packets. There is a maximum allowable size for packets and this maximum size varies depending on network configuration and equipment limitations. If a packet arrives at a switch or gateway and it is too large, the data it carries is divided among two or more smaller packets before being forwarded. This is called fragmentation.

When fragmented packets arrive at their destination, they are reassembled and read. If the fragments do not arrive together, they must be held until all of the fragments arrive. Reassembly of a packet requires all of the fragments.

The FortiGate unit automatically reassembles fragmented packets before processing them because fragmented packets can evade security measures. This reassembly of packets affects TCP, UDP and IP packets. There can be some variation though in what process does the reassembling. The IPS engine, nTurbo and the kernel all can do defragmentation.

For example, you have configured the FortiGate unit to block access to the example.org web site. Any checks for example.com will fail if a fragmented packet arrives and one fragment contains `http://www.exa` while the other contains `mple.com/`. Viruses and malware can be fragmented and avoid detection in the same way. The FortiGate unit will reassemble fragmented packets before examining network data to ensure that inadvertent or deliberate packet fragmentation does not hide threats in network traffic.

Non-standard ports

Most traffic is sent on a standard port based on the traffic type. The FortiGate unit recognizes most traffic by packet content rather than the TCP/UDP port and uses the proper IPS signatures to examine it. Protocols recognized regardless of port include DHCP, DNP3, FTP, HTTP, IMAP, MS RPC, NNTP, POP3, RSTP, SIP, SMTP, and SSL, as well as the supported IM/P2P application protocols.

In this way, the FortiGate unit will recognize HTTP traffic being sent on port 25 as HTTP rather than SMTP, for example. Because the protocol is correctly identified, the FortiGate unit will examine the traffic for any enabled HTTP signatures.

Negotiation codes

Telnet and FTP servers and clients support the use of negotiation information to allow the server to report what features it supports. This information has been used to exploit vulnerable servers. To avoid this problem, the FortiGate unit removes negotiation codes before IPS inspection.

HTTP URL obfuscation

Attackers encode HTML links using various formats to evade detection and bypass security measures. For example, the URL `www.example.com/cgi.bin` could be encoded in a number of ways to avoid detection but still

work properly, and be interpreted the same, in a web browser.

The FortiGate prevents the obfuscation by converting the URL to ASCII before inspection.

HTTP URL obfuscation types

Encoding type	Example
No encoding	http://www.example.com/cgi.bin/
Decimal encoding	http://www.example.com/cgi.bin/
URL encoding	http://www.example.com/%43%47%49%2E%42%49%4E%2F
ANSI encoding	http://www.example.com/%u0063%u0067%u0069%u002E%u0062%u0069%u006E/
Directory traversal	http://www.example.com/cgi.bin/test/..

HTTP header obfuscation

The headers of HTTP requests or responses can be modified to make the discovery of patterns and attacks more difficult. To prevent this, the FortiGate unit will:

- remove junk header lines
- reassemble an HTTP header that's been folded onto multiple lines
- move request parameters to HTTP POST body from the URL

The message is scanned for any enabled HTTP IPS signatures once these problems are corrected.

HTTP body obfuscation

The body content of HTTP traffic can be hidden in an attempt to circumvent security scanning. HTTP content can be GZipped or deflated to prevent security inspection. The FortiGate unit will uncompress the traffic before inspecting it.

Another way to hide the contents of HTTP traffic is to send the HTTP body in small pieces, splitting signature matches across two separate pieces of the HTTP body. The FortiGate unit reassembles these 'chunked bodies' before inspection.

Microsoft RPC evasion

Because of its complexity, the Microsoft Remote Procedure Call protocol suite is subject to a number of known evasion techniques, including:

- SMB-level fragmentation
- DCERPC-level fragmentation
- DCERPC multi-part fragmentation

- DCERPC UDP fragmentation
- Multiple DCERPC fragments in one packet

The FortiGate unit reassembles the fragments into their original form before inspection.

Defending against DoS attacks

A denial of service is the result of an attacker sending an abnormally large amount of network traffic to a target system. Having to deal with the traffic flood slows down or disables the target system so that legitimate users can not use it for the duration of the attack.

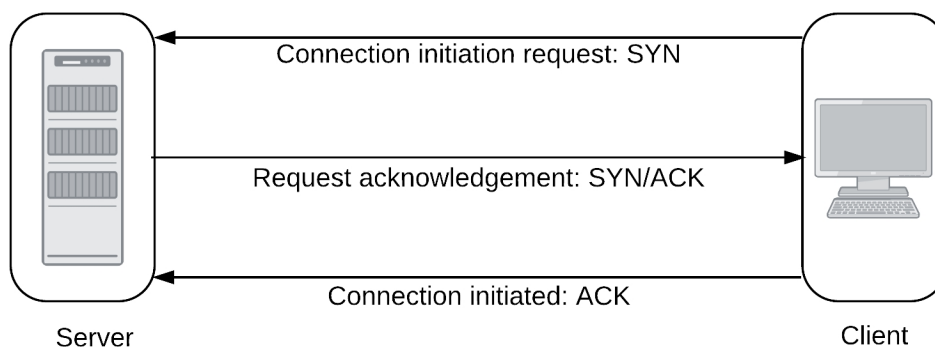

Any network traffic the target system receives has to be examined, and then accepted or rejected. TCP, UDP, and ICMP traffic is most commonly used, but a particular type of TCP traffic is the most effective. TCP packets with the SYN flag are the most efficient DoS attack tool because of how communication sessions are started between systems.

The “three-way handshake”

Communication sessions between systems start with establishing a TCP/IP connection. This is a simple three step process, sometimes called a “three-way handshake,” initiated by the client attempting to open the connection.

1. The client sends a TCP packet with the SYN flag set. With the SYN packet, the client informs the server of its intention to establish a connection.
2. If the server is able to accept the connection to the client, it sends a packet with the SYN and the ACK flags set. This simultaneously acknowledges the SYN packet the server has received, and informs the client that the server intends to establish a connection.
3. To acknowledge receipt of the packet and establish the connection, the client sends an ACK packet.

Establishing a TCP/IP connection

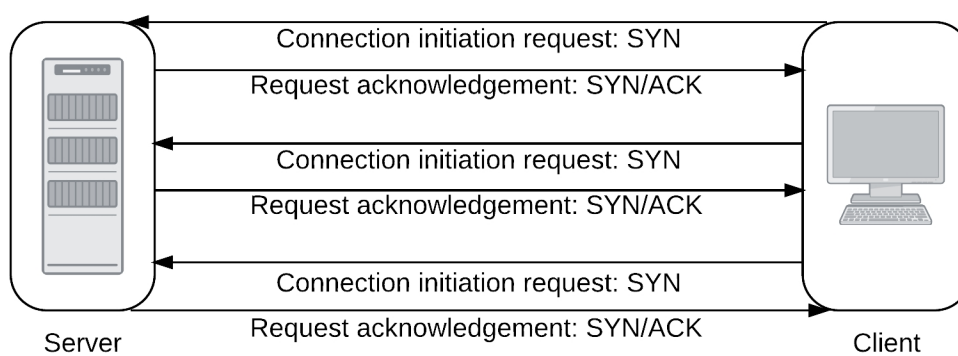

The three-way handshake is a simple way for the server and client to each agree to establish a connection and acknowledge the other party expressing its intent. Unfortunately, the three-way handshake can be used to interfere with communication rather than facilitate it.

SYN flood

When a client sends a SYN packet to a server, the server creates an entry in its session table to keep track of the connection. The server then sends a SYN+ACK packet expecting an ACK reply and the establishment of a connection.

An attacker intending to disrupt a server with a denial of service (DoS) attack can send a flood of SYN packets and not respond to the SYN+ACK packets the server sends in response. Networks can be slow and packets can get lost so the server will continue to send SYN+ACK packets until it gives up, and removes the failed session from the session table. If an attacker sends enough SYN packets to the server, the session table will fill completely, and further connection attempts will be denied until the incomplete sessions time out. Until this happens, the server is unavailable to service legitimate connection requests.

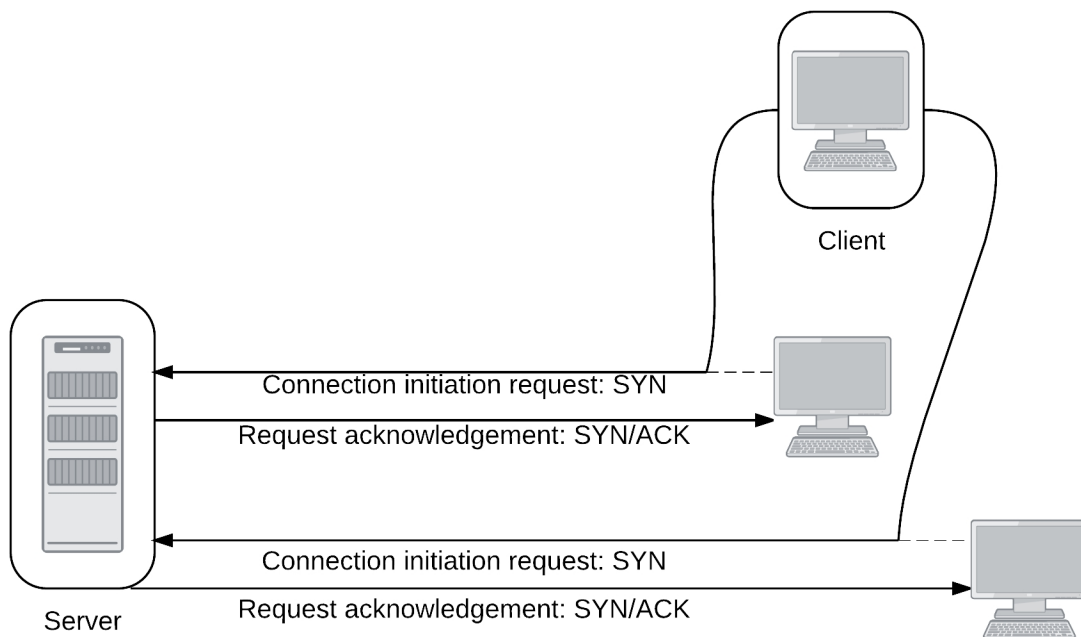

A single client launches a SYN flood attack

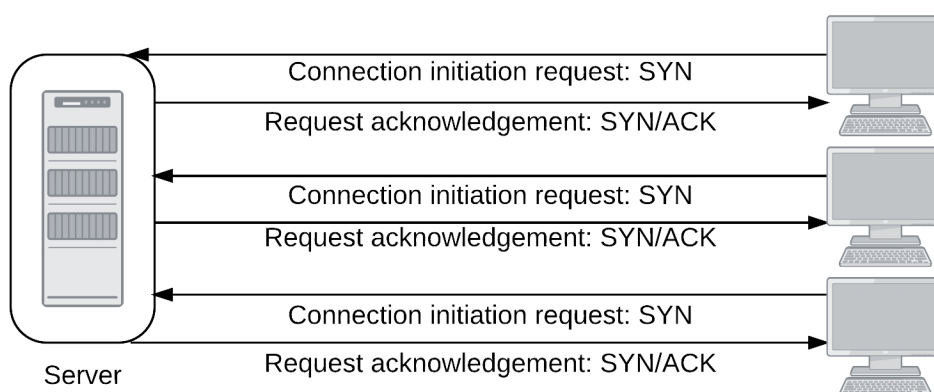

SYN floods are seldom launched from a single address so limiting the number of connection attempts from a single IP address is not usually effective.

SYN spoofing

With a flood of SYN packets coming from a single attacker, you can limit the number of connection attempts from the source IP address or block the attacker entirely. To prevent this simple defense from working, or to disguise the source of the attack, the attacker may spoof the source address and use a number of IP addresses to give the appearance of a distributed denial of service (DDoS) attack. When the server receives the spoofed SYN packets, the SYN+ACK replies will go to the spoofed source IP addresses which will either be invalid, or the system receiving the reply will not know what to do with it.

A client launches a SYN spoof attack**DDoS SYN flood**

The most severe form of SYN attack is the distributed SYN flood, one variety of distributed denial of service attack (DDoS). Like the SYN flood, the target receives a flood of SYN packets and the ACK+SYN replies are never answered. The attack is distributed across multiple sources sending SYN packets in a coordinated attack.

Multiple attackers launch a distributed SYN flood

The distributed SYN flood is more difficult to defend against because multiple clients are capable of creating a larger volume of SYN packets than a single client. Even if the server can cope, the volume of traffic may

overwhelm a point in the network upstream of the targeted server. The only defense against this is more bandwidth to prevent any choke points.

Configuring the SYN threshold to prevent SYN floods

The preferred primary defense against any type of SYN flood is the DoS anomaly check for `tcp_syn_flood` threshold. The threshold value sets an upper limit on the number of new incomplete TCP connections allowed per second. If the number of incomplete connections exceeds the threshold value, and the action is set to **Pass**, the FortiGate unit will allow the SYN packets that exceed the threshold. If the action is set to **Block**, the FortiGate unit will block the SYN packets that exceed the threshold, but it will allow SYN packets from clients that send another SYN packet.

The tools attackers use to generate network traffic will not send a second SYN packet when a SYN+ACK response is not received from the server. These tools will not “retry.” Legitimate clients will retry when no response is received, and these retries are allowed even if they exceed the threshold with the action set to **Block**.

SYN proxy

FortiGate units with network acceleration hardware, whether built-in or installed in the form of an add-on module, offer a third action for the `tcp_syn_flood` threshold. Instead of **Block** and **Pass**, you can choose to **Proxy** the incomplete connections that exceed the threshold value.

When the `tcp_syn_flood` threshold action is set to **f**, incomplete TCP connections are allowed as normal as long as the configured threshold is not exceeded. If the threshold is exceeded, the FortiGate unit will intercept incoming SYN packets from clients and respond with a SYN+ACK packet. If the FortiGate unit receives an ACK response as expected, it will “replay” this exchange to the server to establish a communication session between the client and the server, and allow the communication to proceed.

Other flood types

UDP and ICMP packets can also be used for DoS attacks, though they are less common. TCP SYN packets are so effective because the target receives them and maintains a session table entry for each until they time out. Attacks using UDP or ICMP packets do not require the same level of attention from a target, rendering them less effective. The target will usually drop the offending packets immediately, closing the session.

Use the `udp_flood` and `icmp_flood` thresholds to defend against these DoS attacks.

DoS policies

DDoS attacks vary in nature and intensity. Attacks aimed at saturating the available bandwidth upstream of your service can only be countered by adding more bandwidth. DoS policies can help protect against DDoS attacks that aim to overwhelm your server resources.

DoS policy recommendations

- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received.
- It is important to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, although your network may require very different values.
- One way to find the correct values for your environment is to set the action to **Pass** and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the

more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

Inside FortiOS: Denial of Service (DoS) protection

FortiOS DoS protection maintains network integrity and performance by identifying and blocking harmful IPv4 and IPv6-based denial of service (DoS) attacks.

About DoS and DDoS attacks

A denial of service (DoS) occurs when an attacker overwhelms server resources by flooding a target system with anomalous data packets, rendering it unable to service genuine users. A distributed denial of service (DDoS) occurs when an attacker uses a master computer to control a network of compromised systems, otherwise known as a 'botnet', which collectively inundates the target system with excessive anomalous data packets.

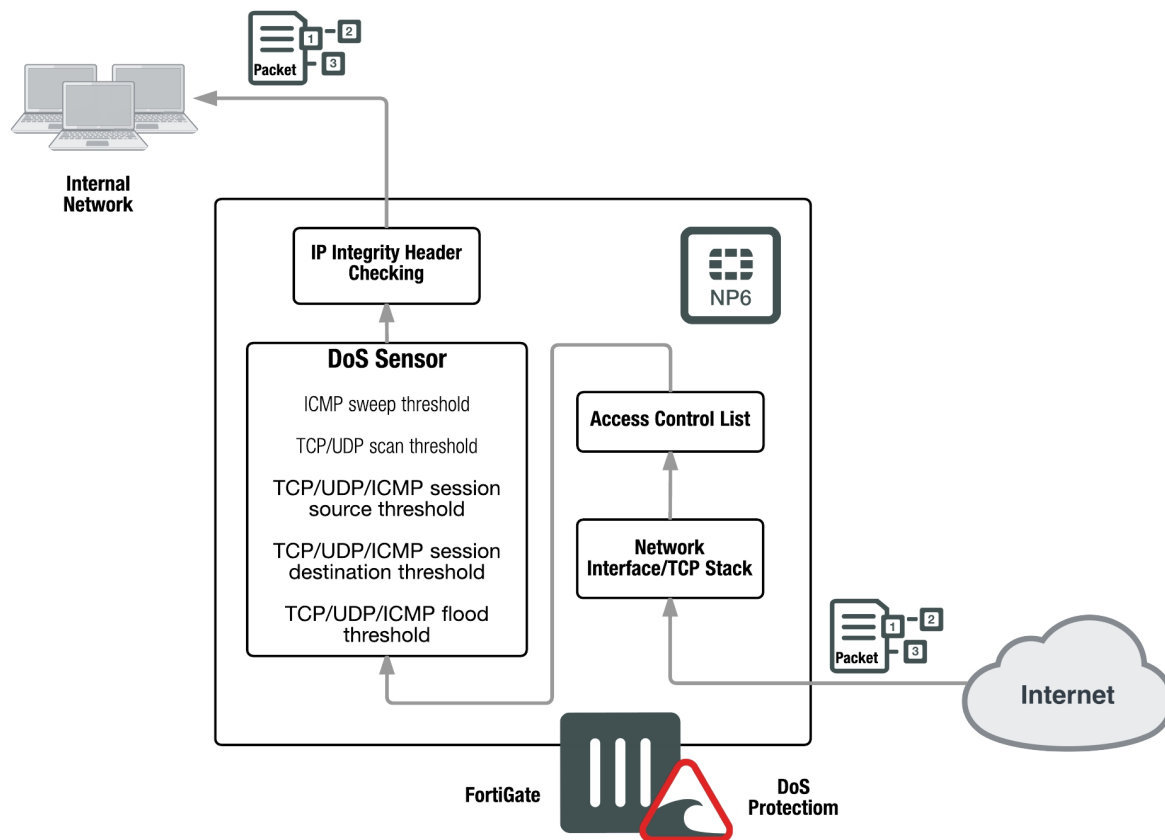

FortiOS DoS and DDoS protection

FortiOS DoS protection identifies potentially harmful traffic that could be part of a DoS or a DDoS attack by looking for specific traffic anomalies. Traffic anomalies that become DoS attacks include: TCP SYN floods, UDP floods, ICMP floods, TCP port scans, TCP session attacks, UDP session attacks, ICMP session attacks, and ICMP sweep attacks. Only traffic identified as part of a DoS attack is blocked; connections from legitimate users are processed normally.

FortiOS applies DoS protection very early in its traffic processing sequence to minimize the effect of a DoS attack on FortiOS system performance. DoS protection is the first step for packets after they are received by a FortiGate interface. Potential DoS attacks are detected and blocked before the packets are sent to other FortiOS systems.

FortiOS also includes an access control list feature that is implemented next. This accelerated ACL technology uses NP6 processors to block traffic (including DoS attacks) by source and destination address and service again before the packets are sent to the FortiGate CPU.

FortiOS DoS protection can operate in a standard configuration or operate out of band in sniffer mode, also known as one-arm mode, similar to intrusion detection systems. When operating in sniffer mode the FortiGate unit detects attacks and logs them without blocking them.

FortiOS DoS policies determine the course of action to take when anomalous traffic reaches a configured packet rate threshold. You can block an attacker, block an interface, block an attacker and interface, or allow traffic to pass through for monitoring purposes. This allows you to maintain network security by gathering information about attacks, monitor potentially offending traffic, or block offenders for the most protection.

FortiGates with NP6 processors also support synproxy DoS protection. An NP6-accelerated TCP SYN proxy offloads the three-way TCP handshake TCP SYN anomaly checking DoS protection to NP6 processors.

FortiOS DDoS prevention

In addition to using DoS protection for protection against DoS attacks, FortiOS includes a number of features that prevent the spread of Botnet and C&C activity. Mobile Malware or Botnet and C&C protection keeps Botnet and C&C code from entering a protected network and compromising protected systems. As a result, systems on the protected network cannot become Botnet clients.

In addition, FortiOS can monitor and block outgoing Botnet connection attempts. Monitoring allows you to find and remove Botnet clients from your network and blocking prevents infected systems from communicating with Botnet sites.

Configuration options

Choose the standard configuration for maximum protection or configure sniffer mode to gather information.

Standard configuration

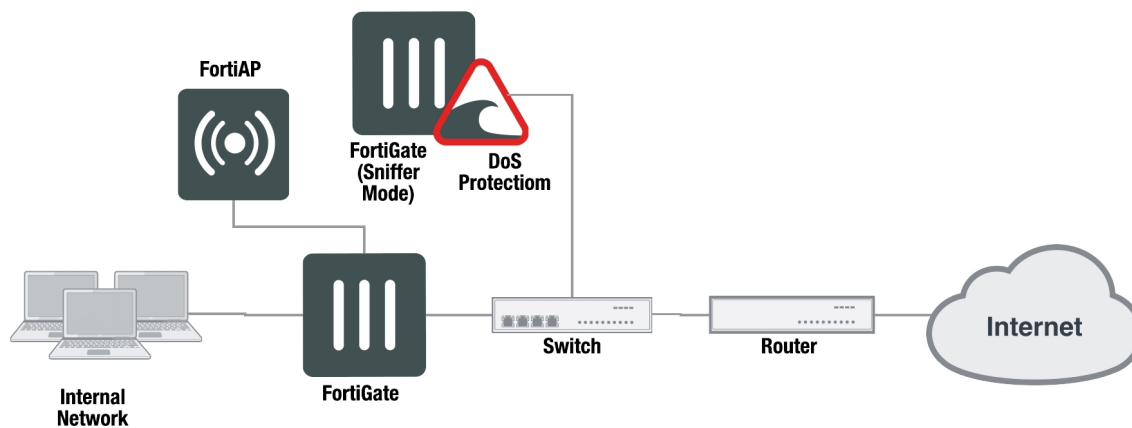

DoS protection is commonly configured on a FortiGate unit that connects a private or DMZ network to the Internet or on a FortiWiFi unit that connects a wireless LAN to an internal network and to the Internet. All Internet traffic or wireless LAN traffic passes through DoS protection in the FortiGate unit or the FortiWiFi unit.

Out of band configuration (sniffer mode)

A FortiGate unit in sniffer mode operates out of band as a one-armed Intrusion Detection System by detecting and reporting attacks. It does not process network traffic nor does it take action against threats. The FortiGate interface operating in sniffer mode is connected to a Test Access Point (TAP) or a Switch Port Analyzer (SPAN) port that processes all of the traffic to be analyzed. The TAP or SPAN sends a copy of the switch traffic to the out of band FortiGate for analysis.

FortiOS records log messages and sends alerts to system administrators when a DoS attack is detected. IDS scanning does not affect network performance or network traffic if the IDS fails or goes offline.

DoS policies

DoS policies provide effective and early DoS detection while remaining light on system resources. They are configured to monitor and to stop traffic with abnormal patterns or attributes. The DoS policy recognizes traffic as a threat when the traffic reaches a user-configured packet rate threshold. The policy then determines the appropriate action. In addition to choosing whether or not to log each type of anomaly, you can choose to pass or block threats.

DoS policy anomaly protection is applied to all incoming traffic to a single FortiGate interface, but you can narrow policies by specifying service, source address, and destination address. The FortiGate unit processes DoS policies in their own respective order first, followed by all other firewall policies.

Hardware acceleration

Hardware acceleration enhances protection and increases the efficiency of your network. FortiOS integrated Content Processors (CPs), Network Processors (NPs), and Security Processors (SPs) accelerate specialized security processing. DoS SYN proxy protection is built in to NP6 processors and many Fortinet Security Processors, like the CE4, XE2, and FE8, to guard against TCP SYN floods. TCP packets with the SYN flag are the most efficient DoS attack tool because of how communication sessions are initiated between systems. NP6 and SP processors can offload TCP SYN flood attack detection and blocking. The SP module increases a FortiGate unit's capacity to protect against TCP SYN flood attacks while minimizing the effect of attacks on the FortiGate unit's overall performance and the network performance. The result is improved capacity and overall system performance.

The FortiGuard Center

The FortiGuard Center shows information on all the most recent FortiGuard news, including information concerning zero-day research and hot intrusion detections. Research papers are also available that concern a variety of current security issues.

To view recent developments, go to <http://www.fortiguard.com/static/intrusionprevention.html>.

Policy configuration

The firewall policies of the FortiGate are one of the most important aspects of the appliance. There are a lot of building blocks and configurations involved in setting up a firewall and it within the policies that a lot of these components come together to form a cohesive unit to perform the firewall's main function, analyzing network traffic and responding appropriately to the results of that analysis.

There are a few different kinds of policies and in most cases these are further divided into IPv4 and IPv6 versions:

- [IPv4 policy](#) - used for managing traffic going through the appliance using IPv4 protocols
- [IPv6 policy](#) - used for managing traffic going through the appliance using IPv6 protocols
- [NAT64 policy](#) - used for managing traffic going through the appliance that converts from IPv6 on the incoming interface to IPv4 on the outgoing interface
- [NAT46 policy](#) - used for managing traffic going through the appliance that converts from IPv4 on the incoming interface to IPv6 on the outgoing interface
- [Multicast policy](#) - used to manage traffic sent to multiple destinations
- [IPv4 access control list](#) - used to filter out packets based on specific IPV4 parameters.
- [IPv6 access control list](#) - used to filter out packets based on specific IPV6 parameters.
- [IPv4 DoS policy](#) - used to prevent malicious or flawed packets on an IPv4 interface from denying access to users.
- [IPv6 DoS policy](#) - used to prevent malicious or flawed packets on an IPv6 interface from denying access to users.

Because the policy determines whether or not NAT will be used, it is also import to look at how to configure:

- [Central SNAT](#) - used for granular controlling when NATing is in use.

Viewing firewall policies

To find a Policy window, follow one of these path in the GUI:

- **Policy & Objects> IPv4 Policy**
- **Policy & Objects> IPv6 Policy**
- **Policy & Objects> NAT64 Policy**
- **Policy & Objects> NAT46 Policy**
- **Policy & Objects> Proxy Policy**
- **Policy & Objects> Multicast Policy**

You may notice other policy options on the left window pane such as:

- **Policy & Objects> IPv4 DoS Policy**
- **Policy & Objects> IPv6 DoS Policy**
- **Policy & Objects> Local InPolicy**

These are different enough that they have their own descriptions in the sections that relate to them.

Menu items

There are some variations, but there are some common elements share by all of them. There is a menu bar across the top. The menu bar will have the following items going from left to right:

- **Create New** button
- **Edit** button
- **Delete** button
- **Search** field
- **Interface Pair View**- Displays the policies in the order that they are checked for matching traffic, grouped by the pairs of Incoming and Outgoing interfaces. For instance, all of the policies referencing traffic from WAN1 to DMZ will be in one section. The policies referencing traffic from DMZ to WAN1 will be in another section. The sections are collapsible so that you only need to look at the sections with policies you are interested in.
- **By Sequence**- Displays the policies in the order that they are checked for matching traffic without any grouping.

Menu items not shared by all policies

- **Policy Lookup** - (IPv4, IPv6)
- **NAT64 Forwarding** - (NAT64)

The Table of Policies

Columns

The tables that make up the Policy window are based on rows which represent individual policies and the columns that represent the various parameters or status within the policy. The columns are customizable by which columns are included and what order they are in.

The table can be laid out a number ways to suit the viewer. There is a column for most of the important pieces of information that you might be interested in seeing, but a lot of them are hidden by default. If you had a large enough screen, you might be able to show all of the columns, but even then it might look a bit busy and cramped together. Figure out which pieces of information are most important to you and hide the rest.

To configure which columns are visible and which are hidden, right click on the header row of the table. This will present a drop down menu. The drop down will be divided into sections. At the top will be the **Selected Columns** which are currently visible, and the next section will be **Available Columns** which show which columns are available to add to the table.

To move a column from the **Available** list to the **Selected** list just click on it. To move a column from the **Selected** list to the **Available** list, it also just takes a click of the mouse. To make the changes show up on the table, go to the bottom of the drop down menu and select **Apply**. Any additions to the table will show up on the right side.

One of the more useful ones that can be added is the ID column. The reason for adding this one is that within the configuration file and CLI, the policies are referenced by their ID number. Some policy settings are only available for configuration in the CLI. If you are looking in the CLI you will see that the only designation for a policy is its number and if you wish to edit the policy or change its order in the sequence you will be asked to move it before or after another policy by referencing its number.

How “Any” policy can remove the Interface Pair View

The FortiGate unit will automatically change the view on the policy list page to **By Sequence** whenever there is a policy containing “any” as the Source or Destination interface. If the **Interface Pair View** is grayed out it is likely that one or more of the policies has used the “any” interface.

By using the “any” interface, the policy should go into multiple sections because it could effectively be any of a number of interface pairings. As mentioned, policies are sectioned by using the interface pairings (for example,

port1 -> port2) and each section has its own specific policy order. The order in which a policy is checked for matching criteria to a packet's information is based solely on the position of the policy within its section or within the entire list of policies as a whole but if the policy is in multiple sections at the same time there is no mechanism for placing the policy in a proper order within all of those sections at the same time because it is a manual process and there is no parameter to compare the precedence of one section or policy over the other. Thus a conflict is created. In order to resolve the conflict the FortiGate firewall removes that aspect of the sections so that there is no need to compare and find precedence between the sections and it therefore has only the Global View to work with.

Policy names

Each policy has a name field. Every policy name must be unique for the current VDOM regardless of policy type. Previous to FortiOS 5.4, this field was optional.

On upgrading from an earlier version of FortiOS to 5.4, policy names are not assigned to old policies, but when configuring new policies, a unique name must be assigned to the policy.

Configuring the Name field

GUI

In the GUI, the field for the policy name is the first field on the editing page.

CLI

In the CLI, the syntax for assigning the policy name is:

```
config firewall [policy|policy6]
  edit 0
    set name <policy name>
  end
```

Disabling policy name requirement

While by default the requirement of having a unique name for each policy is the default, it can be enabled or disabled. Oddly enough, if disabling the requirement is a one time thing, doing it in the CLI is more straightforward.

This setting is VDOM based so if you are running multiple VDOMs, you will have to enter the correct VDOM before entering the CLI commands or turning the feature on or off in the GUI.

GUI

To edit the requirement in the GUI, the ability to do so must be enabled in the CLI. The syntax is:

```
config system settings
  set gui-allow-unnamed-policy [enable|disable]
end
```

Once it has been enabled, the requirement for named policies can be relaxed by going to **System > Feature Visibility**. Allow **Unnamed Policies** can be found under **Additional Features**. Here you can toggle the requirement on and off.

CLI

To change the requirement in the CLI, use the following syntax:

```
config system settings
    set gui-advance policy [enable|disable]
end
```

IPv4 policy

To configure a IPv4 policy in the GUI

1. Go to **Policy & Objects > IPv4 Policy**

The right side window will display a table of the existing IPv4 Policies.

- To edit an existing policy, double click on the policy you wish to edit
- To create a new policy, select the **Create New** icon in the top left side of the right window.

2. Make sure the policy has a name in the **Name** field

By default, a policy is required to have a name, but it is possible to toggle this requirement on or off in the CLI, or in the GUI if you have first enabled the GUI option in the CLI.

- #### 3. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
- #### 4. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)

Alias names for interfaces, if used, appear in the headings for the Interface Pair View or what used to be called the Section View.

Multiple interfaces or ANY interface can be added to a firewall policy. This feature can be enabled or disabled in the GUI by going to the **System > Feature Select** page and toggling **Multiple Interface Policies**.

When selecting the Incoming or Outgoing interface of a policy, there are a few choices:

- The **ANY** interface (choosing this will remove all other interfaces)
- 1 A single specific interface
- 1 multiple specific interfaces (can be added at the same time or one at a time)

The GUI is intuitive and straightforward on how to do this. Click on the "+" symbol in the interface field and then select the desired interfaces from the side menu. There are a couple of ways to do it in the CLI:

1. Set the interfaces all at once:

```
config firewall policy
edit 0
set srcintf wan1 wan2
end
```

2. Set the first interface and append additional ones:

```
config firewall policy
edit 0
set srcintf wan1
append srcintf wan2
end
```

5. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
6. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
7. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
8. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
9. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

- **LEARN** - collects information about the traffic for future analysis
- **IPsec** - for using with IPsec tunnels

Because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Set the **NAT** parameter by toggling the slider button. (gray means it is disabled)

The NAT setting section is affected by whether or not Central NAT is enabled.

If Central NAT is enabled, the only option in Firewall / Network options will be whether to enable or disable NAT. The rest of the NAT parameters will be set in the Central SNAT page.

If Central NAT is disabled, there are two additional settings in the Policy configuration page.

11. Set the **Fixed Port** parameter by toggling the slider button. (gray means it is disabled)
12. Set the **IP Pool Configuration** by selection one of the options of:
- **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the **+** icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the **+** icon next to the **Search** field is a shortcut for creating a new IP Pool.

Security Profiles

13. Enabling the **Use Security Profile Group** option will allow the selection of a profile group instead of selecting the individual profiles for the policy.
14. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The **+** icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **DNS Filter**
- **Application Control**
- **CASI**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**
- **VoIP**
- **ICAP**
- **Web Application Firewall**
- **Proxy Options**
- **SSL/SSH Inspection**

Logging Options

15. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.

16. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
17. Toggle whether or not to **Enable this policy**. The default is enabled.
18. Select the **OK** button to save the policy.

Settings if the DENY action is selected

Enable the Log Violation Traffic setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

Settings if the LEARN action is selected

To get more information on the **LEARN** option, read the Learning mode for Firewall policies topic in [What's new for Firewall in 6.0](#)

Firewall / Network Options

10. Set the **NAT** parameter by toggling the slider button. (gray means it is disabled). Unlike the **ACCEPT** option, whether or not Central NAT is enabled or disabled does not affect this settings options.
11. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
12. Toggle whether or not to **Enable this policy**. The default is enabled.
13. Select the **OK** button to save the policy.

Settings if the IPsec action is selected

VPN Tunnel

10. For the VPN Tunnel field, use the drop down menu to select the VPN tunnel that you want the policy associated with.
 11. Toggle the sliding button to enable or disable the option to **Allow traffic to be initiated from the remote site**
- #### Security Profiles

12. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The "+" icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **DNS Filter**
- **Application Control**
- **CASI**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**

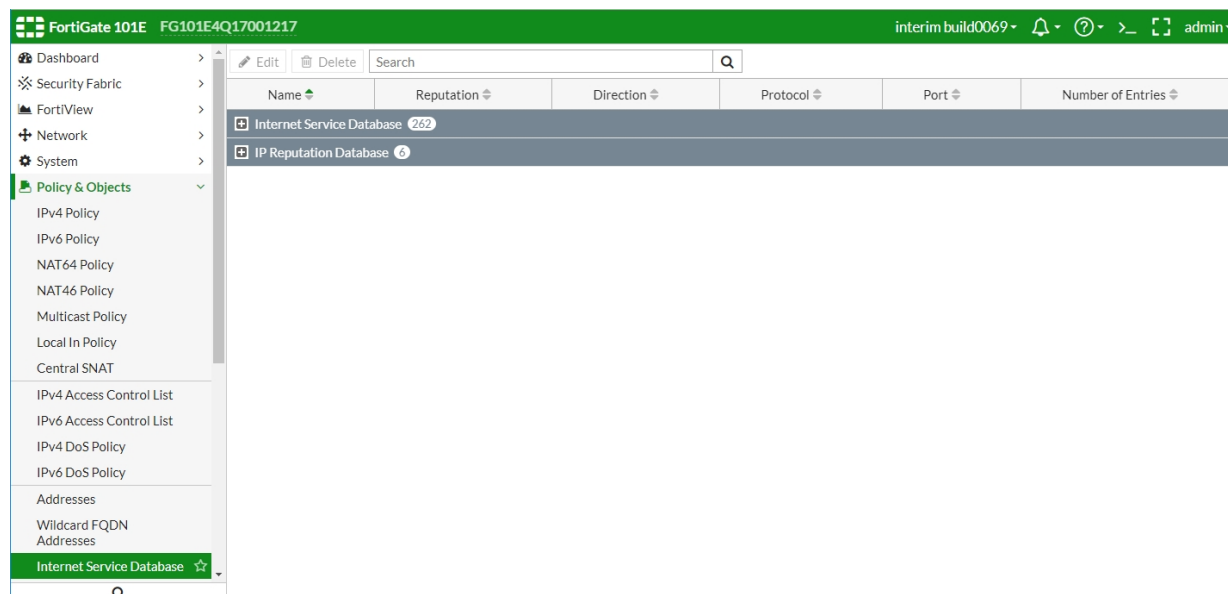

- VoIP
- ICAP
- Web Application Firewall
- Proxy Options
- SSL/SSH Inspection

Logging Options

- Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).
If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
- Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
- Toggle whether or not to **Enable this policy**. The default is enabled.
- Select the **OK** button to save the policy.

ISDB and IRDB in firewall policies

The Internet Service Database (ISDB) and the IP Reputation Database (IRDB) provide similar functionality, so for ease of use, appear together in the GUI.

Use the contents of both, or either database as criteria for inclusion or exclusion in a firewall policy.

Use CLI to define the objects of the ISDB or IRDB objects as parameters within a policy is done within the CLI.

CLI Syntax

```
config firewall policy
edit <ID #>
set internet-service-src {enable|disable}
set internet-service-src-id <ID #>
```

```

set internet-service-src-custom <name>
set internet-service-src-negate {enable|disable}
end

```

CLI options

Option	Description
<code>internet-service-src</code>	Enables or disables the use of Internet Services source for this policy. If enabled, destination address and service are not used.
<code>internet-service-src-id</code>	Internet Service ID Examples: <ul style="list-style-type: none"> • 65536 Google-Others • 65537 Google-Web
<code>internet-service-src-custom</code>	Custom Internet Service name This custom name must already be configured.
<code>internet-service-src-negate</code>	Enables or disables the use of Internet Services in source for this policy. If enabled, <code>internet-service-src</code> specifies what the service must NOT be.

Similar settings are also used in Traffic Shaping policies.

IPv6 policy

To configure a IPv6 policy in the GUI

1. Go to **Policy & Objects > IPv6 Policy**

The right side window will display a table of the existing IPv6 Policies.

- To edit an existing policy, double click on the policy you wish to edit
- To create a new policy, select the **Create New** icon in the top left side of the right window.

2. Make sure the policy has a name in the **Name** field

By default, a policy is required to have a name, but it is possible to toggle this requirement on or off in the CLI, or in the GUI if you have first enabled the GUI option in the CLI.

- #### 3. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other

interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).

4. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
5. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
6. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
7. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
8. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
9. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Set the NAT parameter by toggling the slider button.(gray means it is disabled)
11. Set the **IP Pool Configuration** by selection one of the options of:
 - **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected:

- An additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.
- An additional option to **Preserve the Source Port** will appear as a toggle option. If the slider button is grayed out it is disabled.

Security Profiles

12. Enabling the **Use Security Profile Group** option will allow the selection of a profile group instead of selecting the individual profiles for the policy.

13. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The "+" icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **Application Control**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**
- **VoIP**
- **ICAP**

Logging Options

14. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).
If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
15. Add a comment to give a detailed description of the policy in the **Comments** field (up to 1023 characters).
16. Toggle whether or not to **Enable this policy**. The default is enabled.
17. Select the **OK** button to save the policy.

Settings if the DENY action is selected

Enable the **Log Violation Traffic** setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the **Comments** field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

NAT64 policy

To configure a NAT64 policy in the GUI

1. Go to **Policy & Objects > NAT64 Policy**

The right side window will display a table of the existing NAT64 Policies.

- To edit an existing policy, double click on the policy you wish to edit
 - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
 3. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)

4. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. The source in this case is an IPv6 Address object of the initiating traffic. When the field is selected a window will slide out from the right. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
5. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source Address** field. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
6. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
7. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
8. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Skip the NAT setting. This type of policy is intended only for traffic that is being NATed from IPv6 to IPv4, because without NATing the traffic couldn't reach its destination, so disabling NAT would be pointless.
11. Set the **IP Pool Configuration** by selection one of the options of:
 - **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.

12. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).
If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
13. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
14. Toggle whether or not to **Enable this policy**. The default is enabled.
15. Select the **OK** button to save the policy.

Settings if the DENY action is selected

Enable the **Log Violation Traffic** setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

NAT46 policy

To configure a NAT46 policy in the GUI

1. Go to **Policy & Objects > NAT46 Policy**

The right side window will display a table of the existing NAT46 Policies.

- To edit an existing policy, double click on the policy you wish to edit
 - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
 3. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
 4. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 6. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
 7. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 8. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Skip the NAT setting. This type of policy is intended only for traffic that is being NATed from IPv4 to IPv6, because without NATing the traffic couldn't reach its destination, so disabling NAT would be pointless.
11. Set the **Fixed Port** parameter by toggling the slider button. (gray means it is disabled)
12. Set the **IP Pool Configuration** by selection one of the options of:
 - **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the **+** icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the **+** icon next to the **Search** field is a shortcut for creating a new IP Pool.

14. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).
If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
15. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
16. Toggle whether or not to **Enable this policy**. The default is enabled.
17. Select the **OK** button to save the policy.

Settings if the **DENY** action is selected

Enable the **Log Violation Traffic** setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

Central SNAT

The Central NAT feature is not enabled by default. When `central-nat` is enabled, `nat` option under IPv4 policies is skipped and SNAT must be done via `central-snat-map`.

- Info messages and redirection links have been added to IPv4 policy list and dialog to indicate the above
- If NGFW mode is policy-based, then it is assumed that central-nat (specifically SNAT) is enabled implicitly
- The option to toggle NAT in central-snat-map policies has been added (previously it was only shown in NGFW policy-based mode).
- In central-snat policy dialog, the port-mapping fields for the original port have been updated to accept ranges.
- Nat will be skipped in firewall policy if per vdom central nat is enabled.
- The Central SNAT window contains a table of all of the Central SNAT policies.

To toggle the feature on or off, use the following commands:

```
config system settings
  set central-nat [enable | disable]
end
```

When Central NAT is enabled the **Central SNAT** section will appear under the Policy & Objects heading in the GUI.

To configure a Central SNAT entry in the GUI

1. Go to **Policy & Objects > Central SNAT**

The right side window will display a table of the existing Central SNAT entries.

- To edit an existing entry, double click on the policy you wish to edit
 - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface(s)** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available interfaces. Selecting a listed interface will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.
 3. Set the **Outgoing Interface(s)** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available interfaces. Selecting a listed interface will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.
 4. Set the **Source Address** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available address objects. Selecting a listed object will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 5. Set the **Destination Address** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available address objects. Selecting a listed object will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.

Under the NAT Heading

6. Set the **IP Pool Configuration** parameter by selecting either **Use Outgoing Interface Address** or **Use Dynamic IP Pool**.
 - If Use Dynamic IP Pool is chosen, a field will appear just beneath the option that is used to select which IP Pool object will be used. Set the IP Pool by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available objects.
7. Set the **Protocol** parameter.

There are 5 options for the **Protocol**.

- **ANY** - any protocol traffic
 - **TCP** - TCP traffic only. Protocol number set to 6
 - **UDP** - UDP traffic only. Protocol number set to 17
 - **SCTP** - SCTP traffic only. Protocol number set to 132
 - **Specify** - User can specify the traffic filter protocol by setting the protocol number in the field.
6. If the IP Pool is of the type: Overload, **Explicit Port Mapping** can be enabled.

To enable or disable, use the check box. Once enabled, the following additional parameters will appear.

 - **Original Source Port** - in the left number field, set the starting number of the source port range.
 - **Translated Port** - in the left number field, set the starting number of the translated port range. If it is a single port range leave the right number field alone. If the right number field is set to a number higher than the left, the right number field for the Original Source Port will change to make sure the 2 number ranges have a matching number of ports.
 7. Select the **OK** button to save the entry.

To configure Central SNAT in the CLI

1. Using the CLI interface of your choice, run the following command to get to the correct context.

```
config firewall central-snat-map
```

- To edit an existing entry, run the command `show` or `show full-configuration` to get a listing of all of the entries in the map. Take note of the policy ID for the entry to be edited.
- To create a new entry the next step will use the policy ID 0 which will check for an unused ID number and create an entry with that number.

2. Edit or create an entry with the correct policy ID

```
edit <policyID number>
```

Run the following commands to set the parameters of the entry:

```
set status [enable|disable]
set orig-addr <valid address object preconfigured on the FortiGate>
set srcintf <name of interface on the FortiGate>
set dst-addr <valid address object preconfigured on the FortiGate>
set dstintf <name of interface on the FortiGate>
set protocol <integer for protocol number>
set orig-port <integer for original port number>
set nat-port <integer for translated port number>
set comments <string>
```

3. Save the entry by running the command `end` or `next`.

Example scenarios to showing how CLI treats central-nat

Make nat available regardless of NGFW mode.

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat enable
end
```

Hide nat-port if nat-ippool is not set or NAT is disabled.

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat disable
end
```

Change orig-port to accept range

```
config firewall central-snat-map
edit 1
    set orig-addr "192-86-1-86"
    set srcintf "port23"
    set dst-addr "192-96-1-96"
    set dstintf "port22"
    set nat-ippool "pool1"
    set protocol 17
    set orig-port 2896-2897 (help text changed to: Original port or port range).
    set nat-port 35804-35805
end
```

IPv4 access control list

The **IPv4 Access Control List** is a specialized policy for denying IPv4 traffic based on:

- the incoming interface
- the source addresses of the traffic
- the destination addresses of the traffic
- the services or ports the traffic is using

The only action available in this policy is **DENY**

For more information on see [Access Control Lists](#)

To configure a IPv4 access control list entry in the GUI

1. Go to **Policy & Objects > IPv4 Access Control List**

The right side window will display a table of the existing IPv4 Access Control List entries.

- To edit an existing entry, double click on the policy you wish to edit
 - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
 3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 6. Toggle whether or not to **Enable this policy**. The default is enabled.
 7. Select the **OK** button to save the policy.

To configure a IPv4 access control list entry in the CLI

Use the following syntax:

```
config firewall acl
```

```

edit <acl Policy ID #>
    set status enable
    set interface <interface>
    set srcaddr <address object>
    set dstaddr <address object>
    set service <service object>
end
end

```

IPv6 access control list

The **IPv6 Access Control List** is a specialized policy for denying IPv6 traffic based on:

- the incoming interface
- the source addresses of the traffic
- the destination addresses of the traffic
- the services or ports the traffic is using

The only action available in this policy is **DENY**

To configure a IPv6 access control list entry in the GUI

1. Go to **Policy & Objects > IPv6 Access Control List**

The right side window will display a table of the existing IPv6 Access Control List entries.

- To edit an existing entry, double click on the policy you wish to edit
 - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
 3. Set the **Source IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 4. Set the **Destination IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 6. Toggle whether or not to **Enable this policy**. The default is enabled.
 7. Select the **OK** button to save the policy.

To configure a IPv6 access control list entry in the CLI

Use the following syntax:

```

config firewall acl6
    edit <acl Policy ID #>
        set status enable
        set interface <interface>
        set srcaddr <address object>
        set dstaddr <address object>
        set service <service object>
    end
end

```

IPv4 DoS policy

To configure a IPv4 DoS policy in the GUI

1. Go to **Policy & Objects > IPv4 DoS Policy**

The right side window will display a table of the existing IPv4 DoS Policies.

- To edit an existing policy, double click on the policy you wish to edit
- To create a new policy, select the **Create New** icon in the top left side of the right window.

2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.

3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).

4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.

5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).

6. Set the parameters for the various traffic anomalies.

All of the anomalies that profiles have been created for are in 2 tables. These tables break up the anomaly profiles into **L3 Anomalies** and **L4 Anomalies**. All of the anomalies have the following parameters that can be set on a per anomaly or per column basis.

- Status - enable or disable the indicated profile
- Logging - enable or disable logging of the indicated profile being triggered
- Action - whether to Pass or Block traffic when the threshold is reached
- Threshold - the number of anomalous packets detected before triggering the action.

The listing of anomaly profiles includes:

L3 Anomalies

- ip_src_session
- ip_dst_session

L4 Anomalies

- tcp_syn_flood
- tcp_port_scan
- tcp_src_session
- tcp_dst_session
- udp_flood
- udp_scan
- udp_src_session
- udp_dst_session
- icmp_flood
- icmp_sweep
- icmp_src_session

- sctp_flood
- sctp_scan
- sctp_src_session
- sctp_dst_session

7. Toggle whether or not to **Enable this policy**. The default is enabled.
8. Select the **OK** button to save the policy.

Example

The company wishes to protect against Denial of Service attack. They have chosen some where they wish to block the attacks of the incidence goes above a certain threshold and for some others they are just trying to get a baseline of activity for those types of attacks so they are letting the traffic pass through without action.

- The interface to the Internet is on WAN1
- There is no requirement to specify which addresses are being protected or protected from.
- The protection is to extend to all services.
- The TCP attacks are to be blocked
- The UDP, ICMP, and IP attacks are to be recorded but not blocked.
- The SCTP attack filters are disabled
- The tcp_syn_flood attack's threshold is to be changed from the default to 1000

Configuring the DoS policy in the GUI

1. Go to **Policy & Objects > Policy > DoS**.
2. Create a new policy
3. Fill out the fields with the following information:

Field	Value
Incoming Interface	wan1
Source Address	all
Destination Addresses	all
Service	ALL

L3 Anomalies

Name	Status	Logging	Action	Threshold
ip_src_session	enabled	enabled	Pass	5000
ip_dst_session	enabled	enabled	Pass	5000

L4 Anomalies

Name	Status	Logging	Action	Threshold
tcp_syn_flood	enabled	enabled	Block	1000
tcp_port_scan	enabled	enabled	Block	<default value>
tcp_src_session	enabled	enabled	Block	<default value>
tcp_dst_session	enabled	enabled	Block	<default value>
udp_flood	enabled	enabled	Pass	<default value>
udp_scan	enabled	enabled	Pass	<default value>
udp_src_session	enabled	enabled	Pass	<default value>
udp_dst_session	enabled	enabled	Pass	<default value>
icmp_flood	enabled	enabled	Pass	<default value>
icmp_sweep	enabled	enabled	Pass	<default value>
icmp_src_session	enabled	enabled	Pass	<default value>
icmp_dst_session	enabled	enabled	Pass	<default value>
sctp_flood	not enabled	not enabled	Pass	<default value>
sctp_scan	not enabled	not enabled	Pass	<default value>
sctp_src_session	not enabled	not enabled	Pass	<default value>
sctp_dst_session	not enabled	not enabled	Pass	<default value>

4. Toggle the button next to **Enable this policy** to **ON**.

5. Select **OK**.

Configuring the IPv4 DoS policy in the GUI

Using the CLI of your choice, enter the following commands:

```
config firewall DoS-policy
edit 0
set status enable
set interface wan1
set srcaddr all
set dstaddr all
set service ALL
config anomaly
edit "tcp_syn_flood"
set status enable
```

```
        set log disable
        set action block
        set threshold 1000
    next
edit "tcp_port_scan"
    set status enable
    set log disable
    set action block
    set threshold 1000
next
edit "tcp_src_session"
    set status enable
    set log disable
    set action block
    set threshold 5000
next
edit "tcp_dst_session"
    set status enable
    set log disable
    set action block
    set threshold 5000
next
edit "udp_flood"
    set status enable
    set log disable
    set action pass
    set threshold 2000
next
edit "udp_scan"
    set status enable
    set log disable
    set action pass
    set quarantine none
    set threshold 2000
next
edit "udp_src_session"
    set status enable
    set log disable
    set action pass
    set threshold 5000
next
edit "udp_dst_session"
    set status enable
    set log disable
    set action pass
    set threshold 5000
next
edit "icmp_flood"
    set status enable
    set log disable
    set action pass
    set threshold 250
next
edit "icmp_sweep"
    set status enable
    set log disable
    set action pass
```

```
        set threshold 100
      next
    edit "icmp_src_session"
      set status enable
      set log disable
      set action pass
      set threshold 300
    next
    edit "icmp_dst_session"
      set status enable
      set log disable
      set action pass
      set threshold 1000
    next
    edit "ip_src_session"
      set status disable
      set log enable
      set action pass
      set threshold 5000
    next
    edit "ip_dst_session"
      set status disable
      set log enable
      set action pass
      set threshold 5000
    next
    edit "sctp_flood"
      set status disable
      set log disable
      set action pass
      set threshold 2000
    next
    edit "sctp_scan"
      set status disable
      set log disable
      set action pass
      set threshold 1000
    next
    edit "sctp_src_session"
      set status disable
      set log disable
      set action pass
      set threshold 5000
    next
    edit "sctp_dst_session"
      set status disable
      set log disable
      set action pass
      set threshold 5000
    next
  end
end
end
```

In this example of the CLI, all of the relevant settings have been left in, but some of them are default settings and would not have to have been specifically set to work. For instance, if the action parameter is not set it automatically defaults to pass.

IPv6 DoS policy

To configure a IPv6 DoS policy in the GUI

1. Go to **Policy & Objects > IPv6 DoS Policy**

The right side window will display a table of the existing IPv6 DoS Policies.

- To edit an existing policy, double click on the policy you wish to edit
 - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
 3. Set the **Source IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 4. Set the **Destination IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 6. Set the parameters for the various traffic anomalies.

All of the anomalies that profiles have been created for are in 2 tables. These tables break up the anomaly profiles into **L3 Anomalies** and **L4 Anomalies**. All of the anomalies have the following parameters that can be set on a per anomaly or per column basis.

- Status - enable or disable the indicated profile
- Logging - enable or disable logging of the indicated profile being triggered
- Action - whether to Pass or Block traffic when the threshold is reached
- Threshold - the number of anomalous packets detected before triggering the action.

The listing of anomaly profiles includes:

L3 Anomalies

- ip_src_session
- ip_dst_session

L4 Anomalies

- tcp_syn_flood
- tcp_port_scan
- tcp_src_session
- tcp_dst_session
- udp_flood
- udp_scan
- udp_src_session

- udp_dst_session
 - icmp_flood
 - icmp_sweep
 - icmp_src_session
 - icmp_dst_session
 - sctp_flood
 - sctp_scan
7. Toggle whether or not to **Enable this policy**. The default is enabled.
 8. Select the **OK** button to save the policy.

Configuring the IPv6 DoS policy in the GUI

The configuring of the IPv6 version of the DoS policy is the same as in the IPv4 version , with the exception of first command.

Using the CLI of your choice, enter the following commands:

```
config firewall DoS-policy6
```

The rest of the settings are the same as in IPv4 Dos Policy.

Multicast policy

The **Multicast Policy** GUI page has been updated from previous versions of the firmware to the new GUI look and feel. Some functionality has also been changed.

The DNAT option has been removed from the GUI but is still in the CLI.

To create/edit a multicast policy go to **Policy & Objects > Multicast Policy**. The Listing window on the right will have buttons along the top that will enable you to

- **Create New**
- **Edit**
- **Delete**

There is also a **Search** field that will allow you to search or filter the available policies if you have a lot of them.

To configure a new policy left click on the **Create New** button. This will reveal the New Policy editing window.

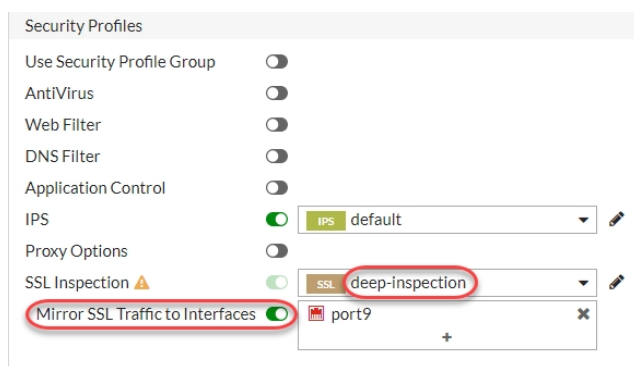

1. Using the drop down menu, fill in the field for **Incoming Interface**. Only one interface can be chosen.
2. Using the drop down menu, fill in the field for **Outgoing Interface**. Only one interface can be chosen.
3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. When the field is selected a window will slide out from the right. In order for a multicast address to be available for selection, the address object needs to have been created already. Only useable address options will be available for selection. This means only multicast address objects and the more generic **all** and **none** options. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
5. Set the **Action** parameter. This will be to either **ACCEPT** or **DENY** the traffic through the policy.

6. Toggle the **Enable SNAT** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled.
7. Use the drop down menu to select a **Protocol**. The options are:
 - **Any**
 - **ICMP**
 - **IGMP**
 - **TCP** - includes **Port Range** fields
 - **UDP** - includes **Port Range** fields
 - **OSPF**
 - **Other** - includes a field for the protocol number
8. Depending on which Protocol is defined, the some other fields may appear.
 - **Port Range** - The first field is for the starting value for the port and the second for the ending value for the port range used by the protocol. Both of these values are inclusive.
 - Protocol field - This appears when the **Other** option is chosen. Enter the value of the protocol number for the protocol you wish to use.
9. Toggle the **Log Allowed Traffic** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled.
10. Toggle the **Enable this policy** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled. By default, this should be enabled
11. Click on the **OK** button to save the policy.

SSL mirroring for policies

You can configure the mirroring of SSL inspected traffic for IPv4 and IPv6 policies in the GUI. To use this option, configure the FortiGate to use SSL deep inspection instead of certificate inspection.

SSL inspection is automatically enabled when you enable a security profile in the policy configuration page. Selecting an SSL inspection profile that uses deep inspection reveals the **Mirror SSL Traffic to Interfaces** option. If you enable mirroring, an **SSL Mirror Terms of Use** agreement appears. Once you accept the agreement, you can select interfaces to mirror the traffic to in the Mirror SSL Traffic to Interfaces field.

Object configuration

As was mentioned earlier, the components of the FortiGate firewall go together like interlocking building blocks. The Firewall objects are a prime example of those building blocks. They are something that can be configured once and then used over and over again to build what you need. They can assist in making the administration of the FortiGate unit easier and more intuitive as well as easier to change. By configuring these objects with their future use in mind as well as building in accurate descriptions the firewall will become almost self documenting. That way, months later when a situation changes, you can take a look at a policy that needs to change and use a different firewall object to adapt to the new situation rather than build everything new from the ground up to accommodate the change.

This chapter includes information about the following Firewall objects:

- [Addresses](#)
- ["Virtual IPs" on page 728](#)
- [IP Pools](#)
- ["Services" on page 742](#)
- ["Firewall schedules" on page 749](#)

UUID support

A Universally Unique Identified (UUID) attribute has been added to some firewall objects, so that the logs can record these UUID to be used by a FortiManager or FortiAnalyzer unit. The objects currently include:

- Addresses, both IPv4 and IPv6
- Address Groups, both IPv4 and IPv6
- Virtual IPs, both IPv4 and IPv6
- Virtual IP groups, both IPv4 and IPv6
- Policies, IPv4, IPv6 and IP64

A UUID is a 16-octet (128-bit) number that is represented by 32 lowercase hexadecimal digits. The digits are displayed in five groups separated by hyphens (-). The pattern is 8-4-4-4-12; 36 digits if you include the hyphens.

Note: UUID is only supported on large-partition platforms ($\geq 128M$)

Addresses

Firewall addresses define sources and destinations of network traffic and are used when creating policies. When properly set up these firewall objects can be used with great flexibility to make the configuration of firewall policies simpler and more intuitive. The FortiGate unit compares the IP addresses contained in packet headers with a security policy's source and destination addresses to determine if the security policy matches the traffic.

The address categories and the types within those categories on the FortiGate unit can include:

- IPv4 addresses
 - IP address and Netmask
 - IP address range

- Geography based address
- Fully Qualified Domain Name (FQDN) address
- Wildcard FQDN
- IPv4 address group
- IPv6 addresses
 - Subnets
 - IP range
 - IPv6 address group
- Multicast addresses
 - Multicast IP range
 - Broadcast subnets
- Proxy addresses
 - URL pattern
 - Host Regex match
 - URL category
 - Http method
 - User agent
 - HTTP header
 - Advanced (source)
 - Advanced (destination)
- IP Pools (IPv4)
 - Overload
 - One-to-one
 - Fixed port range
 - Port block allocation
- IP pools (IPv6)
- Virtual IP addresses
 - IPv4
 - IPv6
 - NAT46
 - NAT64

Interfaces

When setting up an address one of the parameters that is asked for is the interface. This means that the system will expect to see that address only on the interface that you select. You can only select one interface. If you expect that the address may be seen at more than one interface you can choose the “any” interface option. Whenever, possible it is best to choose a more specific interface than the “any” option because in the GUI configuration of firewall policies there is a drop down field that will show the possible addresses that can be used. The drop down will only show those addresses that can be on the interface assigned for that interface in the policy.

Example:

- You have an address called “XYZ”.
- “XYZ” is set to the WAN1 interface because that is the only interface that will be able to access that address.

- When you are selecting a Source Address in the Web-based Manager for a policy that is using the DMZ the address “XYZ” will not be in the drop-down menu.

When there are only 10 or 20 addresses this is not a concern, but if there are a few hundred addresses configured it can make your life easier.

Addresses, address groups, and virtual IPs must have unique names to avoid confusion in firewall policies. If an address is selected in a policy, the address cannot be deleted until it is deselected from the policy.

Addressing Best Practices Tip

The other reason to assign a specific interface to addresses is that it will prevent you from accidentally assigning an address where it will not work properly. Using the example from earlier, if the “XYZ” address was assigned to the “Any” interface instead of WAN1 and you configure the “XYZ” address.

Addressing Best Practices Tip

Don't specify an interface for VIP objects or other address objects that may need to be moved or approached from a different direction. When configuring a VIP you may think that it will only be associated with a single interface, but you may later find that you need to reference it on another interface.

Example: Some web applications require the use of a FQDN rather than an IP address. If you have a VIP set up that works from the Internet to the Internal LAN you won't be able to use that VIP object to access it from an internal LAN interface.

IPv4 addresses

When creating an IPv4 address there are a number of different types of addresses that can be specified. These include:

- FQDN
- Geography
- IP range
- IP/Netmask
- Wildcard FQDN

Which one chosen will depend on which method most easily yet accurately describes the addresses that you are trying to include with as few entries as possible based on the information that you have. For instance, if you are trying to describe the addresses of a specific company's web server but if you have no idea of how extensive there web server farm is you would be more likely to use a Fully Qualified Domain Name (FQDN) rather than a specific IP address. On the other hand some computers don't have FQDNs and a specific IP address must be used.

The following is a more comprehensive description of the different types of addresses.

FQDN addresses

By using Fully Qualified Domain Name (FQDN) addressing you can take advantage of the dynamic ability of DNS to keep up with address changes without having to manually change the addresses on the FortiGate. FQDN addresses are most often used with external web sites but they can be used for internal web sites as well if there is a trusted DNS server that can be accessed. FQDN addressing also comes in handy for large web sites that may use multiple addresses and load balancers for their web sites. The FortiGate firewall automatically maintains a cached record of all the addresses resolved by the DNS for the FQDN addresses used.

For example, if you were doing this manually and you wanted to have a security policy that involved Google you could track down all of the IP addresses that they use across multiple countries. Using the FQDN address is simpler and more convenient.

When representing hosts by an FQDN, the domain name can also be a subdomain, such as mail.example.com.

Valid FQDN formats include:

- <host_name>.<top_level_domain_name> such as example.com
- <host_name>.<second_level_domain_name>.<top_level_domain_name>, such as mail.example.com

When creating FQDN entries it is important to remember that:

- Wildcards are not supported in FQDN address objects
- While there is a level of convention that would imply it, “www.example.com” is not necessarily the same address of “example.com”. they will each have their own records on the DNS server.

The FortiGate firewall keeps track of the DNS TTLs so as the entries change on the DNS servers the IP address will effectively be updated for the FortiGate. As long as the FQDN address is used in a security policy, it stores the address in the DNS cache.

There is a possible security downside to using FQDN addresses. Using a fully qualified domain name in a security policy means that your policies are relying on the DNS server to be accurate and correct. DNS servers in the past were not seen as potential targets because the thinking was that there was little of value on them and therefore are often not as well protected as some other network resources. People are becoming more aware that the value of the DNS server is that in many ways it controls where users and computers go on the Internet. Should the DNS server be compromised, security policies requiring domain name resolution may no longer function properly.

Creating a Fully Qualified Domain Name address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **FQDN** from the drop down menu.
6. Input the domain name in the **FQDN** field.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled, the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example: FQDN address

You have to create a policy that will govern traffic that goes to a site that has a number of servers on the Internet. Depending on the traffic or the possibility that one of the servers is down network traffic can go to any one of those sites. The consistent factor is that they all use the same Fully Qualified Domain Name.

- The FQDN of the web site: example.com
- The number of ISP connections off of the FortiGate firewall: 2

Configuring the address in the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Fill out the fields with the following information:

Category	Address
Name	BigWebsite.com
Type	FQDN
FQDN	bigwebsite.com
Interface	any
Show in Address List	<enable>
Comments	<Input into this field is optional>

3. Select **OK**.

Configuring the address in the CLI

```
config firewall address
edit BigWebsite.com
set type fqdn
set associated-interface any
set fqdn bigwebsite.com
end
```

Verification

To verify that the addresses were added correctly:

1. Go to **Firewall Objects > Address > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address
edit <the name of the address that you wish to verify>
Show full-configuration
```

Changing the TTL of a FQDN address

To make sure that the FQDN resolves to the most recent active server you have been asked to make sure that the FortiGate has not cached the address for any longer than 10 minutes.

There is no field for the cached time-to-live in the web-based manager. It is only configurable in the CLI. Enter the following commands:

```
config firewall address
edit BigWebsite.com
set cache-ttl 600
end
```

Geography based addresses

Geography addresses are those determined by country of origin.

This type of address is only available in the IPv4 address category.

Creating a geography address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **Geography** from the drop down menu.
6. In the **Country** field, select a single country from the drop down menu.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example: Geography-based address

Configuring the address in the GUI

Your company is US based and has information on its web site that may be considered information that is not allowed to be sent to embargoed countries. In an effort to help reduce the possibility of sensitive information going to those countries you have been asked to set up addresses for those countries so that they can be blocked in the firewall policies.

- One of the countries you have been asked to block is Cuba
- You have been asked to comment the addresses so that other administrators will know why they have been created

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Fill out the fields with the following information

Category	Address
Name	Cuba
Type	Geography

Country	Cuba
Interface	any
Visibility	<enable>
Comments	Embargoed

3. Select **OK**.

Configuring the address in the CLI

Enter the following CLI commands:

```
config firewall address
edit Cuba
set type geography
set country CN
set interface wan1
end
```

Overrides

It is possible to assign a specific ip address range to a customized country ID. Generally, geographic addressing is done at the VDOM level; it could be considered global if you are using the root VDOM, but the geoip-override setting is a global setting.

```
config system geoip-override
edit "test"
set country-id "A0"
config ip-range
edit 1
set start-ip 7.7.7.7
set end-ip 7.7.7.8
next
edit 2
set start-ip 7.7.10.1
set end-ip 7.7.10.255
end
```

- While the setting exists in the configuration file, the system assigns the country-id option automatically.
- While you can use "edit 1" and "edit 2", it is simpler to use "edit 0" and let the system automatically assign an ID number.

After creating a customized Country by using geoip-override command, the New country name has been added automatically to the country list and will be available on the Firewall Address Country field.

Diagnose commands

There are a few diagnose commands used with geographic addresses. The basic syntax is:

```
diagnose firewall ipgeo [country-list | ip-list | ip2country | override |
copyright-notice]
```

Diagnose command	Description
country-list	Listing of all the countries.
ip-list	List of the IP addresses associated with the country
ip2country	Used to determine which country a specific IP address is assigned to.
override	Listing of user defined geography data - items configured by using "config system geoip-override" command.
copyright-notice	Shows the copyright notice.

Click on the diagnose command in the table to connect to the Fortinet Diagnose Wiki page that deals with the command option, to get more information.

IP range addresses

Where the subnet address is good at representing a standardized group of addresses that are subnets the IP Range type of address can describe a group of addresses while being specific and granular. It does this by specifying a continuous set of IP addresses between one specific IP address and another. While it is most common that this range is with a subnet it is not a requirement. For instance, 192.168.1.0/24 and 192.168.2.0/24 would be 2 separate subnets but if you wanted to describe the top half of one and the bottom half of the other you could describe the range of 192.168.1.128-192.168.2.127. It's also a lot easier than trying to calculate the correct subnet mask.

The format would be:

x.x.x.x-x.x.x.x, such as 192.168.110.100-192.168.110.120

There is a notation that is commonly used and accepted by some devices that follows the format:

x.x.x.[x-x], such as 192.168.110.[100-120]

This format is not recognized in FortiOS 5.2 as a valid IP Range.

Creating a IP range address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **Address**(IPv4 addresses) or **IPv6 Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **IP Range** from the drop down menu.

6. In the **Subnet / IP Range** field, enter the range of addresses in the following format: x.x.x.x-x.x.x.x (no spaces)
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu. (This setting is not available for IPv6 addresses)
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example

Example of a IP Range address for a group of computers set aside for guests on the company network.

Field	Value
Category	Address or IPv6 Address
Name	Guest_users
Type	IP Range
Subnet / IP Range	192.168.100.200-192.168.100.240
Interface	Port1
Show in Address List	[on]
Comments	Computers on the 1st floor used by guests for Internet access.

IP Range addresses can be configured for both IPv4 and IPv6 addresses. The only differences in creating an IPv6 IP Range address is that you would choose IPv6 Address for the Category and the syntax of the address in the Subnet/IP Range field would be in the format of 2001:0db8:0000:0002:0:0:0:20-2001:0db8:0000:0004:0:0:0:20

IP / netmask addresses

The subnet type of address is expressed using a host address and a subnet mask. From a strictly mathematical stand point this is the most flexible of the types because the address can refer to as little one individual address or as many as all of the available addresses.

It is usually used when referring to your own internal addresses because you know what they are and they are usually administered in groups that are nicely differentiated along the lines of the old A, B, and C classes of IPv4 addresses. They are also addresses that are not likely to change with the changing of Internet Service Providers (ISP).

When representing hosts by an IP address with a netmask, the IP address can represent one or more hosts. For example, a firewall address can be:

- A single host such as a single computer with the address 192.45.46.45
- A range of hosts such as all of the hosts on the subnet 192.45.46.1 to 192.45.46.255
- All hosts, represented by 0.0.0.0 which matches any IP address

The netmask corresponds to the subnet class of the address being added, and can be represented in either dotted decimal or CIDR format. The FortiGate unit automatically converts CIDR formatted netmasks to dotted decimal format. Example formats:

- Netmask for a class A subnet of 16,777,214 usable addresses: 255.0.0.0, or /8
- Netmask for a class B subnet of 65,534 usable addresses: 255.255.0.0, or /16
- Netmask for a class C subnet of 254 usable addresses: 255.255.255.0, or /24
- Netmask for subnetted class C of 126 usable addresses: 255.255.255.128, or /25
- Netmask for subnetted class C of 62 usable addresses: 255.255.255.128, or /26
- Netmask for subnetted class C of 30 usable addresses: 255.255.255.128, or /27
- Netmask for subnetted class C of 14 usable addresses: 255.255.255.128, or /28
- Netmask for subnetted class C of 6 usable addresses: 255.255.255.128, or /29
- Netmask for subnetted class C of 2 usable addresses: 255.255.255.128, or /30
- Netmask for a single computer: 255.255.255.255, or /32
- Netmask used with 0.0.0.0 to include all IP addresses: 0.0.0.0, or /0

So for a single host or subnet the valid format of IP address and netmask could be either:

x.x.x.x/x.x.x.x, such as 192.168.1.0/255.255.255.0

or

x.x.x.x/x, such as 192.168.1.0/24

Static route configuration

A setting that is found in the IP/Netmask address type that is not found in the other address types is the enabling or disabling of **Static Route Configuration**. Enabling this feature includes the address in the listing of named addresses when setting up a static route.

To use in the GUI

1. Enable the **Static Route Configuration** in the address.
2. Go to **Network > Static Routes** and create a new route.
3. For a **Destination** type, choose **Named Address**.
4. Using the drop down menu, enter the name of the address object in the field just underneath the **Destination** type options.
5. Fill out the other information relevant to the route
6. Select the **OK** button

To enable in the CLI:

```
config firewall address
  edit <address_name>
    set allow-routing enable
  end
```

Creating a subnet address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **IP/Netmask** from the drop down menu.
6. In the **Subnet/IP Range** field, enter the address and subnet mask according to the format x.x.x.x/x.x.x.x or the short hand format of x.x.x.x/x
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Select the desired on/off toggle setting for **Static Route Configuration**.
10. Input any additional information in the **Comments** field.
11. Press **OK**.

Example

Example of a Subnet address for a database server on the DMZ:

Field	Value
Category	Address
Name	DB_server_1
Type	IP/Netmask
Subnet/IP Range	United States
Interface	any
Show in Address List	[on]
Static Route Configuration	[off]
Comments	

Wildcard FQDN

There are a number of companies that use secondary and even tertiary domain names or FQDNs for their websites. Wildcard FQDN addresses are to ease the administrative overhead in cases where this occurs. Sometimes its as simple as sites that still use www. as a prefix for their domain name. If you don't know whether or not the www is being used it's simpler to use a wildcard and include all of the possibilities whether it be example.com, www.example.com or even ftp.example.com.

The following wildcard character instances are supported in wildcard FQDN addresses:

- "?" character
- "*" character in the middle of a phrase

- The "?*" combination

Wildcard FQDN addresses do not resolve to a specific set of IP addresses in the same way that a normal FQDN address does. They are intended for use in SSL exemptions and should not be used as source or destination addresses in policies.

Creating a Fully Qualified Domain Name address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **Wildcard FQDN** from the drop down menu.
6. Input the domain name in the **Wildcard FQDN** field.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example

Example of a FQDN address for a remote FTP server used by Accounting team:

Field	Value
Category	Address
Name	Example.com_servers
Type	Wildcard FQDN
Wildcard FQDN	*.example.com
Interface	any
Show in Address List	[on]
Comments	Secondary and tertiary domain names for example.com

Wildcard FQDNs for SSL deep inspection exemptions

As part of an improvement to SSL deep inspection, wild card FQDN addresses are stored in two tables, one relates to `firewall address`, historic location for the information, and the second location relates to `firewall wildcard-fqdn custom`. The wildcard FQDN in `firewall address` is used by `proxy-policy`. The wildcard FQDN in `firewall wildcard-fqdn custom` is used by `ssl-exempt` in `ssl-ssh-profile`.

During an upgrade from v5 to v6, all wildcard FQDN in firewall address in the v5 configuration will be moved to firewall wildcard-fqdn custom. If the wildcard FQDN is used in a policy in v5, the upgrade process will leave a copy of the wildcard FQDN in firewall address in addition to the one in firewall wildcard-fqdn custom.

Syntax of the firewall wildcard-fqdn custom object:

```
config firewall wildcard-fqdn custom
  edit <string_value>
    set uuid <string_value>
    set wildcard-fqdn <string_value>
    set color <integer 0-32>
    set comment <string_value>
    set visibility {enable|disable}
  next
end
```

Syntax of the firewall wildcard-fqdn group object:

```
config firewall wildcard-fqdn group
  edit "test-group"
    set uuid <string_value>
    set member <string_value> [<string_value>]
    set color 0
    set comment ''
    set visibility enable
  next
end
```

In the CLI, separate group members with a space.

IPv6 addresses

When creating an IPv6 address there are a number of different types of addresses that can be specified. These include:

- Subnet
- IP Range - the details of this type of address are the same as the IPv4 version of this type
- IPv6 FQDN firewall addresses - similar to the IPv4 version.

The IPv6 addresses don't yet have the versatility of the IPv4 address in that they don't have things like geography based addresses, but as IPv6 becomes more mainstream this should change.

Subnet addresses

The Subnet Address type is one that is only used in reference to IPv6 addresses. It represents an IPv6 address subnet. This means that the address will likely be a series of hexadecimal characters followed by a double colon, followed by a "/", and then a number less than 128 to indicate the size of the subnet. An example would be:

fd5e:3c59:35ce:f67e::/64

- The hexadecimal characters represent the IPv6 subnet address.
- The "::" indicates 0's from that point to the left. In an actual address for a computer, the hexadecimal characters that would take the place of these zeros would represent the device address on the subnet.
- /xx, in this case /64 represents the number of bits in the subnet. This will make a range that can potentially include 18,446,744,073,709,551,616 addresses. For those wanting to use English rather than math, that is 18 Quintillion.

Creating a subnet address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **IPv6 Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **Subnet** from the drop down menu.
6. In the **Subnet / IP Range** field, enter the range of addresses in IPv6 format (no spaces)
7. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
8. Input any additional information in the **Comments** field.
9. Press **OK**.

Example

Example of a IP Range address for a group of computers set aside for guests on the company network.

Field	Value
Category	IPv6 Address
Name	IPv6_Guest_user_range
Type	Subnet
Subnet / IP Range	fd5e:3c59:35ce:f67e::/64
Show in Address List	[on]
Comments	

IPv6 FQDN firewall addresses

FQDN firewall addresses can be configured for IPv6.

Syntax in CLI

```
config firewall address6
  edit <address_name>
    set type fqdn
    set fqdn <domain_name>
    set cache-ttl <integer value from 0 to 86400>
  end
```

Firewall IPv6 address templates

You can use the IPv6 address templates to create new IPv6 addresses that share a prefix. Using templates for addresses reduces the chance of configuring an incorrect address due to a typographical error.

- A standard IPv6 address can be divided into three parts:
[IPv6 network prefix] + [subnet segments] + [host address]
- The subnet segments can be split into multiple 4-bit blocks called nibbles
- Each subnet segments represent different geographical or organizational parts of the network. They are represented by 1 or more nibbles.

Example of a prefix:

2001:db8:1234:0000::/64

Section	Description
The yellow highlighted characters	Prefix (48 bits)
The green highlighted characters (zeros)	Place holder for the subnet segments (16 bits)
The red highlighted characters	Subnet mask

The 16 bits that make up the subnet segments can be more granular.

Example: 0011 1111 0000 1101

Segment	Binary	Hexadecimal
Site	0011	0x3
Subsite	1111	0xf
Subnet	0000 1101	0x0d

The resulting network portion of the address is:

2001:db8:1234:3f0d::/64

By changing the mask, the subnet segment could be increased.

2001:db8:1234:0000 0000::/48

2001:db8:1234:0000 0000 0000::/32

This makes more options available for the configuration of the subnet segments. Below is an example of a very basic template:

Edit IPv6 Address Template

Name:

IPv6 Address Prefix:

Subnet Segments ?

Segment Name	Bits	Exclusive	Defined Values
country	4	Disable	
state	4	Disable	
city	4	Disable	
site	4	Disable	
lan	4	Disable	
vlan	4	Disable	

OK Cancel

Using that template, you can see how the GUI could be used to quickly create address objects.

New Address

Category: Address **IPv6 Address** Multicast Address Proxy Address

Name:

Color: Change

You can use the template to enter the subnet prefix alone. You don't have to use the segment portion of the template.

Multicast addresses

Multicast addressing defines a specific range of address values set aside for them. Therefore all IPv4 multicast addresses should be between 224.0.0.0 and 239.255.255.255.

More information on the concepts behind Multicast addressing can be found in the Multicast Forwarding section.

Multicast IP range

This type of address will allow multicast broadcasts to a specified range of addresses.

Creating a multicast IP range address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**.
 - If you use the down arrow next to **Create New**, select **Address**.
3. Choose the **Category, Multicast Address**
4. Input a **Name** for the address object.
5. Select the **Type, Multicast IP Range** from the drop-down menu.
6. Enter the value for the **Multicast IP Range**
7. Select the **Interface** from the drop-down menu.
8. Enable the **Show in Address List** function
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example: Multicast IP range address

The company has a large high tech campus that has monitors in many of its meeting rooms. It is common practice for company wide notifications of importance to be done in a streaming video format with the CEO of the company addressing everyone at once.

The video is High Definition quality so takes up a lot of bandwidth. To minimize the impact on the network the network administrators have set things up to allow the use of multicasting to the monitors for these notifications. Now it has to be set up on the FortiGate firewall to allow the traffic.

- The range being used for the multicast is 239.5.5.10 to 239.5.5.200
 - The interface on this FortiGate firewall will be on port 9
1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
 2. Fill out the fields with the following information

Category	Multicast Address
Name	Meeting_Room_Displays
Type	Multicast IP Range
Multicast IP Range	239.5.5.10-239.5.5.200
Interface	port9

Show in Address List	<enable>
Comments	<Input into this field is optional>

3. Select **OK**.

4. Enter the following CLI command:

```
config firewall multicast-address
edit "meeting_room_display"
set type multicastrange
set associated-interface "port9"
set start-ip 239.5.5.10
set end-ip 239.5.5.200
set visibility enable
next
end
```

To verify that the address range was added correctly:

1. Go to **Policy & Objects > Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall multicast-address
edit <the name of the address that you wish to verify>
Show full-configuration
```

Broadcast subnet

This type of address will allow multicast broadcast to every node on a subnet.

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Multicast Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **Broadcast Subnet** from the drop down menu.
6. In the **Broadcast Subnet** field enter the address and subnet mask according to the format x.x.x.x/x.x.x.x or the short hand format of x.x.x.x/x. (Remember, it needs to be within the appropriate IP range 224.0.0.0 to 239.255.255.255)
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example

Field	Value
Category	Broadcast Subnet

Field	Value
Name	Corpnet-B
Type	Broadcast Subnet
Broadcast Subnet	224.5.5.0/24
Interface	any
Show in Address List	[on]
Comments	Corporate Network devices - Broadcast Group B

Multicast IP addresses

Multicast uses the Class D address space. The 224.0.0.0 to 239.255.255.255 IP address range is reserved for multicast groups. The multicast address range applies to multicast groups, not to the originators of multicast packets. The following table lists the reserved multicast address ranges and describes what they are reserved for:

Reserved Multicast address ranges

Reserved Address Range	Use	Notes
224.0.0.0 to 224.0.0.255	Used for network protocols on local networks. For more information, see RFC 1700.	In this range, packets are not forwarded by the router but remain on the local network. They have a Time to Live (TTL) of 1. These addresses are used for communicating routing information.
224.0.1.0 to 238.255.255.255	Global addresses used for multicasting data between organizations and across the Internet. For more information, see RFC 1700.	Some of these addresses are reserved, for example, 224.0.1.1 is used for Network Time Protocol (NTP).
239.0.0.0 to 239.255.255.255	Limited scope addresses used for local groups and organizations. For more information, see RFC 2365.	Routers are configured with filters to prevent multicasts to these addresses from leaving the local system.

Creating multicast security policies requires multicast firewall addresses. You can add multicast firewall addresses by going to **Firewall Objects > Address > Addresses** and selecting **Create New > Multicast Address**. The factory default configuration includes multicast addresses for Bonjour (224.0.0.251-224.0.0.251), EIGRP (224.0.0.10-224.0.0.100), OSPF (224.0.0.5-224.0.0.60), all_hosts (224.0.0.1-224.0.0.1), and all_routers (224.0.0.2-224.0.0.2).

Proxy addresses

This category of address is different from the other addresses in that it is not designed to be used in the normal firewall policy configuration. It is intended to be used only with explicit web proxies.

In some respects they can be like a FQDN addresses in that they refer to an alpha-numeric string that is assigned to an IP address, but then goes an additional level of granularity by using additional information and criteria to further specify locations or types of traffic within the website itself. In depth information on Explicit Proxy Addressing can be found in [WAN Optimization](#), but it is worth laying out the steps of how to create an address object for this category.

Creating an proxy address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Proxy Address**.
4. Input a **Name** for the address object.
5. For the **Type** field, select one of the options from the drop down menu.

Within the Explicit Proxy Address category there are 8 types of addresses. Each of these types will have associated field(s) that also need to have values entered to make the object specific to it's address.

Type = URL Pattern

- In the **Host** field, choose from drop down menu
- In the **URL Path Regex** field, enter the appropriate string

Host Regex Match

- In the **Host Regex Pattern** field, enter the appropriate string

URL Category

- In the **Host** field, choose from drop down menu
- In the **URL Category** field, choose from drop down menu

HTTP Method

- In the **Host** field, choose from drop down menu
- In the **Request Method** field, choose from drop down menu

The options are:

- CONNECT
- DELETE
- GET
- HEAD
- OPTIONS
- POST
- PUT
- TRACE

User Agent

- In the **Host** field, choose from drop down menu
- In the **User Agent** field, choose from drop down menu

The options are:

- Apple Safari
- Google Chrome
- Microsoft Internet Explorer or Spartan
- Mozilla Firefox
- Other browsers

HTTP Header

- In the **Host** field, choose from drop down menu
- In the **Header Name** field, enter the appropriate string value
- In the **Header Regex** field, enter the appropriate string value

Advanced (Source)

- In the **Host** field, choose from drop down menu
- In the **Request Method** field, choose from drop down menu (see **HTTP Method** type for option list)
- In the **User Agent** field, choose from drop down menu (see **User Agent** type for option list)
- In the **Header Group** table, create, edit or delete **Header Name** strings and associated **Header Regex** strings

Advance (Destination)

- In the **Host** field, choose from drop down menu
- In the **Host Regex Pattern** field, enter the appropriate string
- In the **URL Category** field, choose from drop down menu

6. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
7. Input any additional information in the **Comments** field.
8. Press **OK**.

Proxy address groups

To create a Proxy address group:

1. Go to **Policy & Objects > Addresses**.
2. Click on **+ Create New** to get the drop down menu. Select **Address Group**.
3. In the **Category** field, choose **Proxy Group**.
4. Fill in a descriptive name in the **Group Name** field.
5. If you wish, use the **Change** link to change the **Color** of icons in the GUI. There are 32 color options.
6. In the Type field, select whether the group will be a **Source Group** (composed of source addresses) or a **Destination Group** (composed of destination addresses).
7. Select anywhere in the **Members** field to bring forth the pane of potential members for selection to the group.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled, the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Click on **OK**.

Internet services

In FortiOS 5.4, support was added for Internet Service objects which could be used with **FortiView**, **Logging**, **Routing** and **WAN Load Balancing**. Now they can be added to firewall policies as well.

There is an either or relationship between Internet Service objects and destination address and service combinations in firewall policies. This means that a destination address and service can be specified in the policy OR an Internet service, not both.

CLI

The related CLI options/syntax are:

```
config firewall policy
edit 1
set internet-service 1 5 10
set internet-service-custom test
set internet-service-negate [enable|disable]
end
```

GUI

In the policy listing page you will notice that if an Internet Service object is used, it will be found in both the **Destination** and **Service** column.

In the policy editing page the **Destination Address**, now **Destination** field now has two types, **Address** and **Internet Service**.

New Policy		Select Entries
Name	Citrix access	Address Internet Service
Incoming Interface	port1	Search
Outgoing Interface	port2	<ul style="list-style-type: none"> Citrix-FTP(S) Citrix-IMAP(S) Citrix-NetBIOS.Name.Service Citrix-NetBIOS.Session.Service Citrix-SMTP(S) Citrix-SSH Citrix-Web CNN-FTP(S) CNN-SMTP(S) Dropbox-DNS Dropbox-NetBIOS.Name.Service
Source	all	
Destination	<ul style="list-style-type: none"> Citrix-DNS Citrix-FTP(S) Citrix-IMAP(S) Citrix-NetBIOS.Name.Service Citrix-NetBIOS.Session.Service Citrix-SMTP(S) Citrix-SSH Citrix-Web CNN-FTP(S) 	

Address groups

Address groups are designed for ease of use in the administration of the device. If you have a number of addresses or address ranges that will commonly be treated the same or require the same security policies, you can put them into address groups, rather than entering multiple individual addresses in each policy refers to them.

The use of groups is not required. If you have a number of different addresses you could add them individually to a policy and the FortiGate firewall will process them just as quickly and efficiently as if they were in a group, but the chances are that if you have used a group once you could need to use it again and depending on the number of addresses involved entering them individually for each policy can become tedious and the likelihood of an address being missed becomes greater. If you have a number of policies using that combination of addresses it is much easier to add or subtract addresses from the group than to try and remember all of the firewall policies that combination of addresses was used in. With the group, you only have to make the one edit and it is used by any firewall policy using that address group.

Because security policies require addresses with homogenous network interfaces, address groups should contain only addresses bound to the same network interface, or to Any.

For example, if address 1.1.1.1 is associated with port1, and address 2.2.2.2 is associated with port2, they cannot be in the same group. However, if 1.1.1.1 and 2.2.2.2 are configured with an interface of Any, they can be grouped, even if the addresses involve different networks.

There are 3 Categories of Address groups to choose from:

- IPv4 Group
- IPv6 Group
- Proxy Group

You cannot mix different categories of addresses within a group, so whether or not it makes sense from an administrative purpose to group certain addresses together, if some are IPv4 and some are IPv6, it cannot be done.

Creating an address group

1. Go to **Policy & Objects > Addresses**.
2. Select the down arrow next to **Create New**, select **Address Group**.
3. Choose the **Category**, that is applicable to the proposed selection of addresses.
4. Input a **Group Name** for the address object.

Depending on which **Category** has been chosen the configurations will differ slightly

IPv4 group

1. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
2. Select the desired on/off toggle setting for **Show in Address List**.
3. Select the desired on/off toggle setting for **Static Route Configuration**.

IPv6 group

1. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
2. Select the desired on/off toggle setting for **Show in Address List**.

Proxy group

1. Select which Type, either **Source Group** or **Destination Group**.
2. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
3. Select the desired on/off toggle setting for **Show in Address List**.

Irrespective of the Category the groups all have the same final configuration options:

1. Input any additional information in the **Comments** field.
2. Press **OK**.

UUID support

Syntax:

```
config firewall {address|addres6|addgrp|addgrp6}
edit 1
    set uuid <example uuid: 8289ef80-f879-51e2-20dd-fa62c5c51f44>
next
end
```

Virtual IPs

The mapping of a specific IP address to another specific IP address is usually referred to as Destination NAT. When the Central NAT Table is not being used, FortiOS calls this a Virtual IP Address, sometimes referred to as a VIP. FortiOS uses a DNAT or Virtual IP address to map an External IP address to an IP address. This address does not have to be an individual host, it can also be an address range. This mapping can include all TCP/UDP

ports or if Port Forwarding is enabled it will only refer to the specific ports configured. Because, the Central NAT table is disabled by default the term Virtual IP address or VIP will be used predominantly.

Virtual IP addresses are typically used to NAT external or Public IP addresses to internal or Private IP addresses. Using a Virtual IP address between 2 internal Interfaces made up of Private IP addresses is possible but there is rarely a reason to do so as the 2 networks can just use the IP addresses of the networks without the need for any address translation. Using a Virtual IP address for traffic going from the inside to the Internet is even less likely to be a requirement, but it is supported.

Something that needs to be considered when there are multiple Public IP addresses on the external interface(s) is that when a Virtual IP address is used without Port Forwarding enabled there is a reciprocal effect as far as traffic flow is concerned. Normally, on a firewall policy where NAT is enabled, for outgoing traffic the internal address is translated to the Public address that is assigned to the FortiGate, but if there is a Virtual IP address with no port forwarding enabled, then the Internal IP address in the Mapped field would be translated to the IP address configured as the External Address in the VIP settings.

Example

- The assigned External address (WAN1) of the FortiGate unit is 172.12.96.3 with a subnet mask of 255.255.255.128
- There is a Virtual IP address set up to map the external address 172.12.96.127 on WAN1 to the internal IP address of 192.168.1.127
- Port Forwarding is not enabled because you want all allowed traffic going to the external IP address to go to this server.

In this case any outbound traffic from 192.168.1.127 will go out on WAN1 with the IP address of 172.12.96.127 as the source IP address.

In terms of actually using the Virtual IP address, they would be using in the security policies in the same places that other addresses would be used, usually as a Destination Address.

UUID support for VIP

UUID is now supported in for virtual IPs and virtual IP groups. This includes virtual IPs for IPv4, IPv6, NAT46, and NAT64. To view the UUID for these objects in a FortiGate unit's logs, log-uuid must be set to extended mode, rather than policy-only (which only shows the policy UUID in a traffic log). UUID can only be configured through the CLI

Syntax

```
config sys global
  set log-uuid {disable | policy-only | extended}
end
```

There is another type of address that the term “virtual IP address” commonly refers to which is used in load balancing and other similar configurations. In those cases, a number of devices share a separately created virtual IP address that can be sent to multiple possible devices. In FortiOS these are referred to as Virtual Servers and are configured in the “Load Balance” section.

If Central-NAT is enabled in the CLI the GUI will be different.

Instead of **VIP Type**, the field label will be **DNAT & VIP Type**

Instead of **IPv4** the option will be **IPv4 DNAT**

There will also be the addition setting of **Source Interface Filter**.

Commands to set `central-nat`:

```
config system settings
    set central-nat [enable | disable]
end
```

Creating a virtual IP

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**. A drop down menu is displayed. Select **Virtual IP**.
3. From the **VIP Type** options, choose an applicable type based on the IP addressing involved. Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface.

The available options are:

- **IPv4** - IPv4 on both sides of the FortiGate Unit.
 - **IPv6** - IPv6 on both sides of the FortiGate Unit.
 - **NAT46** - Going from an IPv4 Network to an IPv6 Network.
 - **NAT64** - Going from an IPv6 Network to an IPv4 Network.
4. In the **Name** field, input a unique identifier for the Virtual IP.
 5. Input any additional information in the **Comments** field.
 6. The **Color** of the icons that represent the object in the GUI can be changed by clicking on the **[Change]** link and choosing from the 32 colors.

Because the configuration differs slightly for each type the next steps will be under a separate heading based on the type of the VIP

Configuring a VIP for IPv4

In the **Network** section:

7. If an IPv4 type of Virtual IP, select the **Interface** setting.
Using the drop down menu for the Interface Field, choose the incoming interface for the traffic.
The IPv4 VIP Type is the only one that uses this field. This is a legacy function from previous versions so that they can be upgraded without complicated reconfiguration. The External IP address, which is a required field, tells the unit which interface to use so it is perfectly acceptable to choose **"any"** as the interface. In some configurations, if the Interface field is not set to **"any"** the Virtual IP object will not one of the displayed options when choosing a destination address.
8. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. The format of the address will depend on the **VIP Type** option that was selected.

9. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to. There are two fields. If there is a single IP address, use that address in both fields. The format of the address will depend on the **VIP Type** option that was selected.

In the **Optional Filters**

10. Disable/Enable the **Optional Filters**.
If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.
11. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.
 - **Source IP** - Use the standard format for a single IP address
 - **Range** - Enter the first and last members of the range
 - **Subnet** - Enter the IP address of the broadcast address for the subnet.
To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.
12. To specify an allowed Service, toggle the **Services** option to enabled. Set the **Services** parameter by selecting the field with the "+" in the field. This will slide a window out from the right. Single or multiple options can be selected by highlighting the services wanted, unless the **ALL** option is chosen, in which case it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
13. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
14. Select the **Protocol** from
 - **TCP**
 - **UDP**
 - **SCTP**
 - **ICMP**
15. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
16. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
17. Press **OK**.

Example

This example is for a VIP that is being used to direct traffic from the external IP address to a web server on the internal network. The web server is for company use only. The company's public facing web server already used

port 80 and there is only one IP external IP address so the traffic for this server is being listened for on port 8080 of the external interface and being sent to port 80 on the internal host.

Field	Value
VIP Type	IPv4
Name	Internal_Webserver
Comments	Web server with Collaboration tools for Corporate employees
Interface	Any
External IP Address/Range	172.13.100.27 <this would normally be a public IP address>
Mapped IP Address/Range	192.168.34.150
Optional Filters	enabled
Source Address Filter	<list of IP addresses of remote users>
Services	enabled with HTTP in the list
Port Forwarding	enabled
Map to Port	80 - 80

Configuring a VIP for IPv6

In the **Network** section:

7. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv6 format.

8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.

There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv6 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.

If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.

10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.

- **Source IP** - Use the standard format for a single IP address
 - **Range** - Enter the first and last members of the range
 - **Subnet** - Enter the IP address of the broadcast address for the subnet.
To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.
12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
 13. Select the **Protocol** from
 - **TCP**
 - **UDP**
 - **SCTP**
 14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
 15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
 16. Press **OK**.

Configuring a VIP for NAT46

In the **Network** section:

7. Configure the **External IP Address/Range**.
There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv4 format.
8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.
There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv6 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.
If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.
10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.
 - **Source IP** - Use the standard format for a single IP address
 - **Range** - Enter the first and last members of the range
 - **Subnet** - Enter the IP address of the broadcast address for the subnet.

To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.

12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
13. Select the **Protocol** from
 - **TCP**
 - **UDP**
14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
16. Press **OK**.

In order for VIP46 to work correctly, NAT64 must be enabled. To enable NAT64, set the following configuration:

```
conf sys nat64
  set status enable
end
```

Configuring a VIP for NAT64

In the **Network** section:

7. Configure the **External IP Address/Range**.
There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv6 format.
8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.
There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv4 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.
If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.
10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.
 - **Source IP** - Use the standard format for a single IP address
 - **Range** - Enter the first and last members of the range
 - **Subnet** - Enter the IP address of the broadcast address for the subnet.

To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.

12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
13. Select the **Protocol** from
 - **TCP**
 - **UDP**
14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
16. Press **OK**.

FQDN in VIPs

Instead of mapping to an IP address a VIP can use a FQDN(Fully Qualified Domain Name). This has to be configured in the CLI and the FQDN must be an address object that is already configured in the address listing.

The syntax for using a FQDN is:

```
config firewall vip
  edit <VIP id>
    set type fqdn
    set mapped-addr <FQDN address object>
  end
```

Dynamic VIP according to DNS translation

When a dynamic virtual IP is used in a policy, the dynamic DNS translation table is installed along with the dynamic NAT translation table into the kernel. All matched DNS responses will be translated and recorded regardless if they hit the policy. When a client request hits the policy, dynamic NAT translation will occur if it matches a record, otherwise the traffic will be blocked.

Syntax

```
config firewall vip
  edit "1"
    set type dns-translation
    set extip 192.168.0.1-192.168.0.100
    set extintf "dmz"
    set dns-mapping-ttl 604800
    set mappedip "3.3.3.0/24" "4.0.0.0/24"
  end
end
```

Virtual IP groups

Just like other address, Virtual IP addresses can be organized into groups for ease of administration. If you have multiple virtual IPs that are likely to be associated to common firewall policies rather than add them individually to each of the policies you can add the instead. That way, if the members of the group change then any changes made to the group will propagate to all of the policies using that group.

When using a Virtual IP address group the firewall policy will take into account all of the configured parameters of the Virtual IPs: IP addresses, Ports and port types.

Creating a virtual IP group

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**. A drop down menu is displayed. Select **Virtual IP Group**.
3. Select the **Type** for VIP group you wish to create.

The options available are:

- **IPv4** - IPv4 on both sides of the FortiGate Unit.
- **IPv6** - IPv6 on both sides of the FortiGate Unit.
- **NAT46** - Going from an IPv4 Network to an IPv6 Network.
- **NAT64** - Going from an IPv6 Network to an IPv4 Network.

Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface. The options will be:

4. Enter a unique identifier for the group in the **Name** field.
5. Enter any additional information in the **Comments** field.
6. If you wish, use the **Change** link to change the **Color** of icons in the GUI. There are 32 color options.
7. If the **Type** is **IPv4**, the **Interface** field will be available. Use the drop-down menu to select the interface if all of the VIPs are on the same interface. If any of the VIPs are on different interfaces or if any of them are associated with the "any" option, choose the any option for the group.
8. Select anywhere in the **Members** field to bring forth the pane of potential members for selection to the group.
9. Press **OK**.

Configuring IP pools

An IP pool is essentially one in which the IP address that is assigned to the sending computer is not known until the session is created, therefore at the very least it will have to be a pool of at least 2 potential addresses. A quick example would be an IP pool for users of a VPN. IP pools are based upon the version of IP determined by the interface that they are associated with so as expected there are two types of IP pools that can be configured:

- ["Creating a IPv4 pool" on page 736](#)
- ["Creating a IPv6 pool" on page 741](#)

Because of the differences in the configuration for the two types of pools, instructions for configuring them will be done separately.

Creating a IPv4 pool

1. Go to **Policy & Objects > IP Pools**.
2. Select **Create New**.
3. In the **IP Pool Type** field choose **IPv4 Pool**

4. Enter a name in the **Name** field for the new service
5. Include any description you would like in the **Comments** field
6. In the **Type** field choose between:
 - **Overload**
 - **One-to-One**
 - **Fixed Port Range**
 - **Port Block Allocation**

At this point the configurations can start to differ based on the type of type of pool.

For more information on the different types of IP pools, check [IP Pools](#) in the Concepts section.

Overload

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. Enable the **ARP Reply** field by making sure there is a check in the box
9. Select **OK**

Overload example for GUI

In this example, the Sales team needs to connect to an Application Service Provider that does the accounting for the company. As a security measure, the ASP only accepts traffic from a white list of IP addresses. There is 1 public IP address of the company on that list. The Sales team consists of 40 people, so they need to share. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	Sales_Team
Comments	For the Sales team to use to connect to the Accounting ASP
Type	Overload (This is the default)
External IP Range	10.23.56.20 - 10.23.56.20
ARP Reply	enabled

Overload example for CLI

```
config firewall ippool
  edit Sales_Team
    set comments "For the Sales team to use to connect to the Accounting ASP"
    set type overload
    set startip 10.23.56.20
    set endip 10.23.56.20
    set arp-reply enable
    set arp-intf wan1
  end
```

One-to-one

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. Enable the **ARP Reply** field by making sure there is a check in the box.
9. Select **OK**

One-to-one example for GUI

In this example, the external IP address of the mail server is part of a range assigned to the company but not the one that is assigned to the Internet facing interface. A VIP has been set up but in order to properly resolve Reverse DNS lookups the mail server always has to use a specific IP address. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	Mail-Server
Comments	So the correct IP address is resolved on Reverse DNS look ups of the mail server.
Type	One-to-one
External IP Range	10.23.56.21 - 10.23.56.21
ARP Reply	enabled

One-to-one example for CLI

```
config firewall ippool
  edit Mail-Server
    set comments "So the the correct IP address is resolved on reverse DNS look ups of
      the mail server."
    set type one-to-one
    set startip 10.23.56.21
    set endip 10.23.56.21
    set arp-reply enable
    set arp-intf wan1
  end
```

Fixed port range

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. Fort the **Internal IP Range** fields, enter the lowest and highest addresses in the range.
9. Enable the **ARP Reply** field by making sure there is a check in the box
10. Select **OK**

Fixed port range example for GUI

In this example, the company has a range of 10 IP address that they want to be used by employees on a specific subnet for NATing. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	IPPool-3
Comments	IP range to be used by outgoing traffic
Type	Fixed Port Range
External IP Range	10.23.56.22 - 10.23.56.31
Internal IP Range	192.168.23.1 - 192.168.23.254
ARP Reply	enabled

Fixed port range example for CLI

```
config firewall ippool
edit IPPool-3
    set comments "So the the correct IP address is resolved on reverse DNS look ups of
        the mail server."
    set type fixed-port-range
    set startip 10.23.56.22
    set endip 10.23.56.31
    set source-startip 192.168.23.1
    set source-endip 192.168.23.254
    set arp-reply enable
    set arp-intf wan1
end
```

Port block allocation

- For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
- In the **Block Size** field, either type in the value or use the up or down arrows to set the value of the block size.
- In the **Blocks Per User** field, either type in the value or use the up or down arrows to set the value for the number of blocks per user.
- Enable the **ARP Reply** field by making sure there is a check in the box
- Select **OK**

Port block allocation timeout

The port block allocation timeout value is configurable. The setting is found in the CLI.

The option `pba-timeout` has been added to the firewall ip pool configuration. The availability of this option is dependent on the type option being set to port-block-allocation. The timeout value is measured in seconds and is an integer between 3 and 300, with the default being 30.

Syntax:

```
config firewall ippool
  edit <name of PBA pool>
    set type port-block-allocation
    set pba-timeout <integer>
  end
```

Port block allocation example for GUI

In this example, an small ISP is setting up NATing for its clients, but to be fair it is putting some restrictions on the number of connections each client can have so that no one hogs all of the possible ports and addresses. The external interface is port12.

Field	Value
IP Pool Type	IPv4 Pool
Name	Client-IPPool
Comments	IP Pool for clients to access the Internet
Type	Port Block Allocation
External IP Range	10.23.75.5 - 10.23.75.200
Block Size	64
Blocks Per User	8
ARP Reply	enabled

Port block allocation example for CLI

```
config firewall ippool
  edit Client-IPPool
    set comments "IP Pool for clients to access the Internet"
    set type port-block-allocation
    set startip 10.23.75.5
    set endip 10.23.75.200
    set block-size 64
    set num-blocks-per-user 8
    set permit-any-host disable
    set arp-intf wan1
    set arp-reply enable
    set arp-intf port12
  end
```

Creating a IPv6 pool

1. Go to **Policy & Objects > IP Pools**.
2. Select **Create New**.
3. In the IP Pool Type field choose **IPv6 Pool**
4. Enter a name in the **Name** field for the new service
5. Include any description you would like in the **Comments** field
6. For the **External IP Range** fields, enter the lowest and highest addresses in the range.

IPv6 example for GUI

In this example, there is a similar situation to the One-to-one example earlier. There is a mail server that needs to be resolved to a specific IP address in Reverse DNS look-ups. The difference in this case is the company is an early adopter of IPv6 connectivity to the Internet.

Field	Value
IP Pool Type	IPv6 Pool
Name	Mail-svr-ipv6
Comments	Registered IPv6 address for mail server
External IP Range	fd2f:50ec:cdea:0663::1025 - fd2f:50ec:cdea:0663::1025

Port block allocation example for CLI

```
config firewall ippool6
edit Mail-svr-ipv6
set comments "Registered IPv6 address for mail server"
set startip fd2f:50ec:cdea:663::102
set endip fd2f:50ec:cdea:663::1025
end
```

Creating NAT46 IP pool and multiple (secondary) NAT64 prefixes

Policies that translate between IPv4 and IPv6 can use IPv4 address pools or IPv6 prefixes to be used in the policies, giving more options to the configuration of addresses.

NAT46

For using the ippool in NAT46 policies, first enable the use of ippools and then set the names of the ippool(s).

```
config firewall policy46
edit 1
set uuid e9c6ca3e-72ea-51e7-554a-1185693d03eb
set srcintf "wan1"
set dstintf "internal7"
set srcaddr "external-net4"
set dstaddr "internal-vip46"
set action accept
set schedule "always"
set service "ALL"
set ippool enable
```

```
set poolname "intit-pool6"  
end
```

NAT64

In order to use these options in the NAT64 firewall policies the new settings `secondary-prefix status` and `secondary-prefix options` have to be configured as in the example below.

```
config system nat64  
set nat64-prefix 2001::/96  
set secondary-prefix enable  
config secondary-prefix  
edit 1  
set nat64-prefix 2002::/94  
next  
edit 2  
set nat64-prefix 2003::/95  
end  
end
```

The primary prefix must have a length of 96, but the secondary prefixes can be different lengths

Services

While there are a number of services already configured within FortiOS, the firmware allows for administrators to configure their own. The reasons for doing this usually fall into one or more of the following categories:

- The service is not common enough to have a standard configuration
- The service is not established enough to have a standard configuration
- The service has a standard port number but there is a reason to use a different one:
 - Port is already in use by another service
 - For security reasons, want to avoid standard port

When looking at the list of preconfigured services it may seem like there are a lot, but keep in mind that the theoretical limit for port numbers is 65,535. This gives a fairly good sized range when you are choosing what port to assign a service but there are a few points to keep in mind.

- Most of the well known ports are in the range 0 - 1023
- Most ports assigned by the Internet Corporation for Assigned Names and Numbers (ICANN) will be in the 1024 - 49151 range
- Port numbers between 49,152 and 65,535 are often used for dynamic, private or ephemeral ports.

There are 3 Service objects that can be added and configured:

- Categories
- Services
- Service Groups

Categories

In order to make sorting through the services easier, there is a field to categorize the services. Because selecting a category is part of the process for creating a new service, the configuration of categories will be explained first.

The services can be sorted into the following groups:

- General
- Web Access
- File Access
- Email
- Network Services
- Authentication
- Remote Access
- Tunneling
- VoIP, Messaging and Other Applications
- Web Proxy
- Uncategorized

The categories are for organization purposes so there is not many settings when creating a new one.

Creating a new service category

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Category**
3. Input a **Name** for the category.
4. Input any additional information in the **Comments** field.
5. Press **OK**.

Example

You plan on adding a number of devices such as web cameras that will allow the monitoring of the physical security of your datacenter. A number of non-standard services will have to be created and you would like to keep them grouped together under the heading of "Surveillance"

Example of a new category in the GUI

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Category**.
2. Fill out the fields with the following information

Field	Value
Name	Surveillance
Comments	For DataCenter Surveillance Devices

3. Select **OK**.

Example of a New Category in the CLI

Enter the following CLI command:

```
config firewall service category
edit Surveillance
set comment "For DataCenter Surveillance Devices"
end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services**. Select the Category Settings icon . A listing of the categories should be displayed.
2. Enter the following CLI command:

```
config firewall service category
show
```

This should bring up all of the categories. Check to see that the new one is displayed.

Configuring a new service

Occasionally, the preconfigured list of services will not contain the needed service. There are a few variations in the creation of a service depending upon the protocol type, but the first steps in the creation of the service are common to all the variations.

To create a new service:

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Service**
3. Enter a name in the **Name** field for the new service
4. Include any description you would like in the **Comments** field
5. In the **Service Type** field choose between **Firewall** and **Explicit Proxy**.
6. Enable the toggle in the **Show in Service List**. If you can't see the service when you need to select it, it serves very little purpose.
7. For the **Category** field, choose the appropriate category from the **Category** drop down menu. If none is chosen, the **Uncategorized** option will be chosen by default.

Protocol options

This is the section where the configuration options of the service will differ depending on the type of protocol chosen. (The Step numbers will all continue on from the common step sequence).

The protocol options for **Firewall** service type are:

- **TCP/UDP/SCTP**
- **ICMP**
- **ICMP6**
- **IP**

The protocol options for **Proxy** service type are:

- **ALL**
- **CONNECT**
- **FTP**
- **HTTP**

- **SOCKS-TCP**
- **SOCKS-UDP**

TCP/UDP/SCTP

- For the **Protocol Type** field, choose **TCP/UDP/SCTP** from the drop down menu
- For the **Address** field, choose IP Range or **FQDN** (Fully Qualified Domain Name) if there is to be a specific destination for the service. Depending on which type of address is selected, the field value needs to be filled with a FQDN string or an IP address in one of the 3 standard IPv4 address formats:
 - x.x.x.x - for a specific address
 - x.x.x.x/x - for a subnet
 - x.x.x.x-x.x.x.x - for a range of specific addresses
- Configure the **Destination Port** by:
 - Select from the drop down menu, **TCP**, **UDP** or **SCTP**
 - Enter the low end to the port range in the field indicated by grayed out **Low**.
 - Enter the high end of the port range in the field indicated by grayed out **High**. If there is only a single port in the range **High** can be left empty
 - Multiple ports or port ranges can be added by using the "+" at the beginning of the row
 - Rows can be removed by using the trash can symbol at the end of the row
- If required, you can **Specify Source Ports** for the service by enabling the toggle switch.
 - The **Src Port** will match up with a **Destination Port**
 - **Src Ports** cannot be configured without there being a value for the **Destination Port**
 - The same rules for configuring the **Destination Ports** applies to the **Src Ports**
- Select **OK** to confirm the configuration

Example

Example settings for a TCP protocol service. In this case, it is for an administrative connection to web servers on the DMZ. The protocol used is HTTPS which would normally use port 443, but that is already in use by another service such as Admin access to the firewall or an SSL-VPN connection.

Field	Value
Name	Example.com_WebAdmin
Comments	Admin connection to Example.com Website
Service Type	Firewall
Show in Service List	enabled
Category	Web Access
Protocol Options	
Protocol Type	TCP/UDP/SCTP

Field	Value
IP/FQDN	<left blank>
Destination Port	<ul style="list-style-type: none"> • Protocol: TCP • Low: 4300 • High: <left blank>
Specify Source Ports	<disabled>

Creating a new TCP/UDP/SCTP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
edit Example.com_WebAdmin
set comment "Admin connection to Example.com Website"
set category Web Access
set protocol TCP/UDP/SCTP
set tcp-portrange 4300
end
end
```

ICMP / ICMP6

- For the **Protocol Type** field, choose **ICMP** or **ICMP6** from the drop down menu
- In the **Type** field enter the appropriate type number based on the information found in ["ICMP Types and Codes" on page 1](#) or in ["ICMPv6 Types and Codes" on page 1](#), depending on whether the **Protocol Type** is **ICMP** or **ICMPv6**
- In the **Code** field enter the appropriate code number for the type, if applicable, based on the information found in ["ICMP Types and Codes" on page 1](#) or in ["ICMPv6 Types and Codes" on page 1](#), depending on whether the **Protocol Type** is **ICMP** or **ICMPv6**
- Select **OK** to confirm the configuration

Example

Example settings for an ICMP.service. In this case it has been set up for some special testing of ICMP packets.

Field	Value
Name	ICMP test #4
Comments	For testing of proprietary network scanner
Service Type	Firewall
Show in Service List	enabled
Category	Network Services

Field	Value
Protocol Options	
Protocol Type	ICMP
Type	7
Code	<left blank>

Creating a new ICMP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
edit ICMP test4
    set comment "For testing of proprietary network scanner"
    set category Network Services
    set protocol ICMP
    set icmptype 7
end
end
```

IP

- For the **Protocol Type** field, choose **IP** from the drop down menu
- In the **Protocol Number** field enter the numeric value based on the information found in "[Protocol Number](#)" on [page 1](#)
- Select **OK** to confirm the configuration

Example

Example settings for an IP.service. In this case it has been set up to communicate via an old protocol called QNX

Field	Value
Name	QNX
Comments	For QNX communications to the Development Lab
Service Type	Firewall
Show in Service List	enabled
Category	Uncategorized
Protocol Options	
Protocol Type	IP
Protocol Number	106

Creating a new ICMP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
edit ICMP test4
    set comment "For QNX communications to the Development Lab "
    set protocol IP
    set icmptype 106
end
end
```

In the CLI examples, the fields for **Show in Service List**, **Service Type** and in the example for IP, **Category** were not set because the values that they would have been set to were the default values and were already correctly set.

ALL/CONNECT/FTP/HTTP/SOCKS-TCP/SOCKS-UDP

These options are available only if the **Service Type** is set to **Explicit Proxy**.

8. For the **Protocol Type** field, choose one of the following from the drop down menu:
 - **ALL**
 - **CONNECT**
 - **FTP**
 - **HTTP**
 - **SOCKS-TCP**
 - **SOCKS-UDP**
9. For the **Address** field, choose IP Range or **FQDN** (Fully Qualified Domain Name) if there is to be a specific destination for the service. Depending on which type of address is selected, the field value needs to be filled with a FQDN string or an IP address in one of the 3 standard IPv4 address formats:
 - x.x.x.x - for a specific address
 - x.x.x.x/x - for a subnet
 - x.x.x.x-x.x.x.x - for a range of specific addresses
10. Configure the **Destination Port** by:
 - Enter the low end to the TCP port range in the field indicated by grayed out **Low**.
 - Enter the high end of the TCP port range in the field indicated by grayed out **High**. If there is only a single port in the range **High** can be left empty
 - Multiple ports or port ranges can be added by using the "+" at the beginning of the row
 - Rows can be removed by using the trash can symbol at the end of the row
11. If required, you can **Specify Source Ports** for the service by enabling the toggle switch.
 - The **Src Port** will match up with a **Destination Port**
 - **Src Ports** cannot be configured without there being a value for the **Destination Port**
 - The same rules for configuring the **Destination Ports** applies to the **Src Ports**
12. Select **OK** to confirm the configuration

Specific addresses in TCP/UDP/SCTP

In the TCP/UDP/SCTP services it is also possible to set the parameter for a specific IP or Fully Qualified Domain Name address. The IP/FQDN field refers to the destination address of the traffic, not the source. This means for example, that you can set up a custom service that will describe in a policy the TCP traffic over port 80 going to the web site example.com, but you cannot set up a service that describes the TCP traffic over port 80 that is coming from the computer with the address 192.168.29.59.

Service groups

Just like some of the other firewall components, services can also be bundled into groups for ease of administration.

Creating a service group

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Service Group**
3. Input a **Group Name** to describe the services being grouped
4. Input any additional information in the **Comments** field.
5. Choose a **Type** of group. The options are **Firewall** or **Explicit Proxy**.
6. Add to the list of **Members** from the drop down menu. Using the + sign beside the field will allow the addition of multiple services.
7. Press **OK**.

Example

Example of a New Service Group:

Field	Value
Group Name	Authentication Services
Comments	Services used in Authentication
Type	Firewall
Members	<ul style="list-style-type: none">• Kerberos• LDAP• LDAP_UDP• RADIUS

Firewall schedules

Firewall schedules control when policies are in effect. When you add a security policy on a FortiGate unit you need to set a schedule to determine the time frame in which that the policy will be functioning. While it is not set by default, the normal schedule would be always. This would mean that the policy that has been created is always function and always policing the traffic going through the FortiGate. The time component of the schedule is based on a 24 hour clock notation or military time as some people would say.

There are two types of schedules: One-time schedules and recurring schedules.

One-time schedule object

One-Time schedules are in effect only once for the period of time specified in the schedule. This can be useful for testing to limit how long a policy will be in effect in case it is not removed, or it can be used for isolated events such as a conference where you will only need a temporary infrastructure change for a few days.

The time frame for a One-time schedule is configured by using a start time which includes, Year | Month | Day | Hour | Minute and a Stop time which includes the same variables. So while the frequency of the schedule is only once it can last anywhere from 1 minute to multiple years.

Configuring a one-time schedule object in the GUI

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule**.
3. From the **Type** options, choose **One-time**.
4. Input a **Name** for the schedule object.
5. If you wish to add a **Color** to the icon in the GUI, you can click on the **Change** link to choose 1 of 32 color options.
6. Choose a **Start Date**.
Selecting the field with the mouse will bring up a interactive calendar graphic that will allow the user to select the date. The date can also be typed in using the format YYYY/MM/DD.
7. Choose a **Start Time**.
The **Start Time** is composed of two fields, **Hour** and **Minute**. Think of setting the time for a digital clock in 24 hour mode. The **Hour** value can be an integer from 0 and 23. The **Minute** value can be from 0 to 59. 0 and 0 would be midnight at the start of the day and 23 and 59 would be one minute to midnight at the end of the day. The value can be entered by keyboard or by using the up and down arrows in the field to select the value.
6. Choose an **End Date**.
Configuration is the same as **Start Date**.
8. Choose a **Stop Time**.
Configuration is the same as **Start Time**.
9. Enable/Disable **Pre-expiration event log**.
This configures the system to create an event log 1 to 100 days before the **End Date** as a warning in case the schedule needs to be extended.
10. If the **Pre-expiration event log** is enabled, set the value for **Number of days before**.
11. Press **OK**.

Example: Firewall schedule - one-time

The company wants to change over their web site image to reference the new year. They have decided to take this opportunity to do some hardware upgrades as well. Their web site is business oriented so they have determined that over New Year's Eve there will be very limited traffic.

- They are going to need a maintenance window of 2 hours bracketing midnight on New Year's Eve.

Configuration in the GUI

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

Type	One-time
Name	NewYearsEve_Maintenance
Start Date	2014/12/31 <use the built in calendar>
End Date	2015/01/01 <use the built in calendar>
Start Time	Hour: 23, Minute: 0
Stop Time	Hour: 1Minute: 0
Pre-expiration event log	<disable>

4. Select **OK**.

To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Configuration in the CLI

1. Enter the following CLI command:

```
config firewall schedule onetime
edit maintenance_window
set start 23:00 2012/12/31
set end 01:00 2013/01/01
next
end
```

To verify that the schedule was added correctly:

1. Enter the following CLI command:

```
config firewall schedule onetime
edit <the name of the schedule you wish to verify>
show full-configuration
```

Recurring schedule object

Recurring schedules are in effect repeatedly at specified times of specified days of the week. The Recurring schedule is based on a repeating cycle of the days of the week as opposed to every x days or days of the month. This means that you can configure the schedule to be in effect on Tuesday, Thursday, and Saturday but not every 2 days or on odd numbered days of the month.

If a recurring schedule has a stop time that is earlier than the start time, the schedule will take effect at the start time but end at the stop time on the next day. You can use this technique to create recurring schedules that run from one day to the next.

Configuring a recurring schedule object in the GUI

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule**.
3. From the **Type** options, choose **Recurring**.
4. Input a **Name** for the schedule object.
5. If you wish to add a **Color** to the icon in the GUI, you can click on the **Change** link to choose 1 of 32 color options.
6. From the **Days** options, choose the day of the week that you would like this schedule to apply to. The schedule will be in effect on the days of the week that have a check mark in the checkbox to the left of the name of the weekday.
7. If the scheduled time is the whole day, leave the **All Day** toggle switch enabled. If the schedule is for specific times during the day, disable the **All Day** toggle switch.
8. If the All Day option is disabled, choose a **Start Time**.
The **Start Time** is composed of two fields, **Hour** and **Minute**. Think of setting the time for a digital clock in 24 hour mode. The **Hour** value can be an integer from 0 and 23. The **Minute** value can be from 0 to 59. 0 and 0 would be midnight at the start of the day and 23 and 59 would be one minute to midnight at the end of the day. The value can be entered by keyboard or by using the up and down arrows in the field to select the value.
7. Choose a **Stop Time**.
Configuration is the same as **Start Time**.
8. Press **OK**.

Because recurring schedules do not work with DENY policies, the strategy when designing a schedule should *not* be to determine when users cannot access a policy but to build the schedules around when it *is* possible to access the policy.

Example: Firewall schedule - recurring

The Company wants to allow the use of Facebook by employees, but only during none business hours and the lunch break.

- The business hours are 9:00 p.m. to 6:00 p.m.
- The Lunch break is 12:00 p.m. to 1:00 p.m.
- The plan is to create a schedule to cover the morning business hours and the afternoon business hours and block access to the Facebook web site during that time.

Configuration in the GUI

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

Type	Recurring
Name	Morning_Business_Hours
Days	Monday, Tuesday, Wednesday, Thursday, Friday
Start Time	Hour = 9, Minute = 0
Stop Time	Hour = 12, Minute = 0

4. Select **OK**.
5. Create a second new schedule.

Type	Recurring
Name	Morning_Business_Hours
Days	Monday, Tuesday, Wednesday, Thursday, Friday
Start Time	Hour = 13, Minute = 0
Stop Time	Hour = 18, Minute = 0

6. Select **OK**.

To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Configuration in the CLI

1. Enter the following CLI command:

```
config firewall schedule recurring
edit Morning_Business_Hours
set day monday tuesday wednesday thursday friday
set start 09:00
set end 12:00
end
```

2. Enter the following CLI command:

```
config firewall schedule recurring
edit Afternoon_Business_Hours
set day monday tuesday wednesday thursday friday
set start 13:00
set end 18:00
end
```

To verify that the schedule was added correctly:

1. Enter the following CLI command:

```
config firewall schedule recurring
edit <the name of the schedule you wish to verify>
```

```
show full-configuration
```

Schedule groups

You can organize multiple firewall schedules into a schedule group to simplify your security policy list. The schedule parameter in the policy configuration does not allow for the entering of multiple schedules into a single policy so if you have a combination of time frames that you want to schedule the policy for then the best approach, rather than making multiple policies is to use a schedule group.

Creating a schedule group object

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule Group**
3. Input a **Name** for the schedule object.
4. In the **Members** field, select the "+" to bring forth the panel for selecting entries.
5. Press **OK**.

Example

Your Internet policy allows employees to visit Social Media sites from company computers but not during what is considered working hours. The offices are open a few hours before working hours and the doors are not locked until a few hours after official closing so work hours are from 9 to 5 with a lunch break from Noon to 1:00 p.m.

Your approach is to block the traffic between 9 and noon and between 1:00 p.m. and 5:00 p.m. This means you will need two schedules for a single policy and the schedule group handles this for you. Schedule groups can contain both recurring and one-time schedules. Schedule groups cannot contain other schedule groups.

Schedule expiration

The schedule in a security policy enables certain aspects of network traffic to occur for a specific length of time. What it does not do however, is police that time. That is, the policy is active for a given time frame, and as long as the session is open, traffic can continue to flow.

For example, in an office environment, Skype use is allowed between noon and 1pm. During that hour, any Skype traffic continues. As long as that session is open, after the 1pm end time, the Skype conversations can continue, yet new sessions will be blocked. Ideally, the Skype session should close at 1pm.

Using a CLI command you can set the schedule to terminate all sessions when the end time of the schedule is reached. Within the config firewall command enter the command:

```
set schedule-timeout enable
```

By default, this option is set to disable.

A few further settings are needed to make this work.

```
config firewall policy
  edit ID
    set firewall-session-dirty check-new
  end

config system settings
  set firewall-session-dirty check-policy-option
end
```

The Policy window will indicate when a policy has become invalid due to its schedule parameters referring only to times in the past.

Firewall-session-dirty setting

The firewall-session-dirty setting has three options

<code>check-all</code>	CPU flushes all current sessions and re-evaluates them. [default]
<code>check-new</code>	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
<code>check-policy-option</code>	Use the option selected in the firewall-session-dirty field of the firewall policy (check-all or check-new, as above, but per policy).

Secure web gateway, WAN optimization, web caching and WCCP

You can use FortiGate WAN optimization and web caching to improve performance and security of traffic passing between locations on your wide area network (WAN) or from the Internet to your web servers. You can also use the FortiGate unit as an explicit FTP and web proxy server. If your FortiGate unit supports web caching, you can also add web caching to any HTTP sessions including WAN optimization, explicit web proxy and other HTTP sessions.

the next sections of this document describes how FortiGate WAN optimization, web caching, explicit web proxy, explicit FTP proxy and WCCP work and also describes how to configure these features.

Before you begin

Before you begin to configure WAN optimization, Web caching, explicit proxies or WCCP, take a moment to note the following:

FortiGate models that support WAN optimization

WAN optimization is available on FortiGate models with internal storage that also support SSL acceleration. Internal storage includes high-capacity internal hard disks, AMC hard disk modules, FortiGate Storage Modules (FSMs) or over 4 Gbytes of internal flash storage. All of these storage locations can provide similar web caching and byte caching performance. If you add more than one storage location (for example, by creating multiple partitions on a storage device, by using more than one FSM, or by using an FSM and AMC hard disk in the same FortiGate unit) you can configure different storage locations for web caching and byte caching.

Distributing WAN optimization, explicit proxy, and web caching to multiple CPU cores

By default WAN optimization, explicit proxy and web caching is handled by half of the CPU cores in a FortiGate unit. For example, if your FortiGate unit has 4 CPU cores, by default two will be used for WAN optimization, explicit proxy and web caching. You can use the following command to change the number of CPU cores that are used.

```
config system global
    set wad-worker-count <number>
end
```

The value for <number> can be between 1 and the total number of CPU cores in your FortiGate unit. Adding more cores may enhance WAN optimization, explicit proxy and web caching performance and reduce the performance of other FortiGate systems.

Dispatching traffic to WAD worker based on source affinity

The `wad-worker` balancing algorithm supports a more balanced dispersal of traffic to the wad processes even, if the bulk of the traffic is coming from a small set of, or single source.

By default, dispatching traffic to WAD workers is based on source affinity. This may negatively affect performance when users have another explicit proxy in front of the FortiGate. Source affinity causes the FortiGate to process the traffic as if it originated from the single (or small set of) ip address of the outside proxy. This results in the use of one, or a small number, of WAD processes.

By disabling `wad-source-affinity` the traffic is balanced over all of the WAD processes. When the `wad-source-affinity` is disabled, the WAD dispatcher will not assign the traffic based on the source IP, but will assign the traffic to available workers in a round-robin fashion.

Handling the traffic by different WAD workers results in losing some of the benefits of using source affinity, as is explained by the warning message that appears when it is disabled:

"WARNING: Disabling this option results in some features to be unsupported. IP-based user authentication, disclaimer messages, security profile override, authentication cookies, MAPI scanning, and some video caches such as YouTube are not supported.

Do you want to continue? (y/n)"

CLI

```
config system global
    set wad-source-affinity {enable|disable}
end
```

Toggling disk usage for logging or wan-opt

Both logging and WAN Optimization use hard disk space to save data. In FortiOS, you cannot use the same hard disk for WAN Optimization and logging.

- If the FortiGate has one hard disk, then it can be used for either disk logging or WAN optimization, but not both. By default, the hard disk is used for disk logging.
- If the FortiGate has two hard disks, then one disk is always used for disk logging and the other disk is always used for WAN optimization.

On the FortiGate, go to **System > Advanced > Disk Settings** to switch between **Local Log** and **WAN Optimization**.

You can also change disk usage from the CLI using the following command:

```
configure system global
    set disk-usage {log | wanopt}
end
```

The Toggle Disk Usage feature is supported on all new "E" Series models, while support for "D" Series models may vary.

Please refer to the [Feature Platform Matrix](#) for more information.

Changing the disk setting formats the disk, erases current data stored on the disk and disables either disk logging or WAN Optimization.

You can configure WAN Optimization from the CLI or the GUI. To configure WAN Optimization from the GUI you must go to **System > Feature Visibility** and turn on WAN Optimization.

Remote logging (including logging to FortiAnalyzer and remote Syslog servers) is not affected by using the single local hard disk for WAN Optimization.

Enabling WAN optimization affects more than just disk logging

In addition to affecting WAN Optimization, the following table shows other features affected by the FortiGate disk configuration.

Features affected by Disk Usage as per the number of internal hard disks on the FortiGate

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
Logging	Supported	Not supported	Supported
Report/Historical FortiView	Supported	Not supported	Supported
Firewall Packet Capture (Policy Capture and Interface Capture)	Supported	Not supported	Supported
AV Quarantine	Supported	Not supported	Supported
IPS Packet Capture	Supported.	Not supported	Supported
DLP Archive	Supported	Not supported	Supported
Sandbox DB & Results	FortiSandbox database and results are also stored on disk, but will not be affected by this feature.		

Example topologies relevant to WAN optimization

FortiGate WAN optimization consists of a number of techniques that you can apply to improve the efficiency of communication across your WAN. These techniques include protocol optimization, byte caching, web caching, SSL offloading, and secure tunneling. Protocol optimization can improve the efficiency of traffic that uses the CIFS, FTP, HTTP, or MAPI protocol, as well as general TCP traffic. Byte caching caches files and other data on FortiGate units to reduce the amount of data transmitted across the WAN. Web caching stores web pages on FortiGate units to reduce latency and delays between the WAN and web servers. SSL offloading offloads SSL decryption and encryption from web servers onto FortiGate SSL acceleration hardware. Secure tunneling secures traffic as it crosses the WAN.

You can apply different combinations of these WAN optimization techniques to a single traffic stream depending on the traffic type. For example, you can apply byte caching and secure tunneling to any TCP traffic. For HTTP and HTTPS traffic, you can also apply protocol optimization and web caching.

You can configure a FortiGate unit to be an explicit web proxy server for both IPv4 and IPv6 traffic and an explicit FTP proxy server. Users on your internal network can browse the Internet through the explicit web proxy server or connect to FTP servers through the explicit FTP proxy server. You can also configure these proxies to protect access to web or FTP servers behind the FortiGate unit using a reverse proxy configuration.

Web caching can be applied to any HTTP or HTTPS traffic, this includes normal traffic accepted by a security policy, explicit web proxy traffic, and WAN optimization traffic.

You can also configure a FortiGate unit to operate as a Web Cache Communication Protocol (WCCP) client or server. WCCP provides the ability to offload web caching to one or more redundant web caching servers.

FortiGate units can also apply security profiles to traffic as part of a WAN optimization, explicit web proxy, explicit FTP proxy, web cache and WCCP configuration. Security policies that include any of these options can also include settings to apply all forms of security profiles supported by your FortiGate unit.

Basic WAN optimization topology

The basic FortiGate WAN optimization topology consists of two FortiGate units operating as WAN optimization peers intercepting and optimizing traffic crossing the WAN between the private networks.

Security device and WAN optimization topology

FortiGate units can be deployed as security devices that protect private networks connected to the WAN and also perform WAN optimization. In this configuration, the FortiGate units are configured as typical security devices for

the private networks and are also configured for WAN optimization. The WAN optimization configuration intercepts traffic to be optimized as it passes through the FortiGate unit and uses a WAN optimization tunnel with another FortiGate unit to optimize the traffic that crosses the WAN.

You can also deploy WAN optimization on single-purpose FortiGate units that only perform WAN optimization. In the out of path WAN optimization topology shown below, FortiGate units are located on the WAN outside of the private networks. You can also install the WAN optimization FortiGate units behind the security devices on the private networks.

The WAN optimization configuration is the same for FortiGate units deployed as security devices and for single-purpose WAN optimization FortiGate units. The only differences would result from the different network topologies.

Out-of-path WAN optimization topology

In an out-of-path topology, one or both of the FortiGate units configured for WAN optimization are not directly in the main data path. Instead, the out-of-path FortiGate unit is connected to a device on the data path, and the device is configured to redirect sessions to be optimized to the out-of-path FortiGate unit.

Single-purpose WAN optimization topology

The following out-of-path FortiGate units are configured for WAN optimization and connected directly to FortiGate units in the data path. The FortiGate units in the data path use a method such as policy routing to redirect traffic to be optimized to the out-of-path FortiGate units. The out-of-path FortiGate units establish a WAN optimization tunnel between each other and optimize the redirected traffic.

Out-of-path WAN optimization

One of the benefits of out-of-path WAN optimization is that out-of-path FortiGate units only perform WAN optimization and do not have to process other traffic. An in-path FortiGate unit configured for WAN optimization also has to process other non-optimized traffic on the data path.

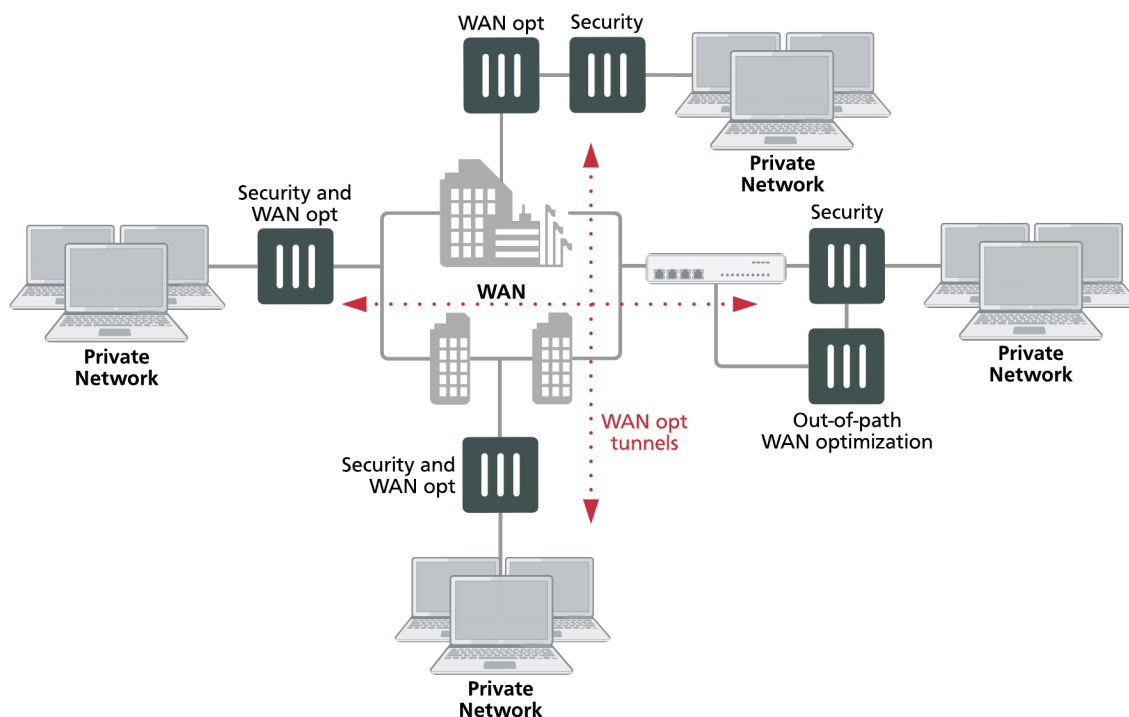

The out-of-path FortiGate units can operate in NAT/Route or transparent mode.

Other out-of-path topologies are also possible. For example, you can install the out-of-path FortiGate units on the private networks instead of on the WAN. Also, the out-of-path FortiGate units can have one connection to the network instead of two. In a one-arm configuration such as this, security policies and routing have to be configured to send the WAN optimization tunnel out the same interface as the one that received the traffic.

Topology for multiple networks

As shown in below, you can create multiple WAN optimization configurations between many private networks. Whenever WAN optimization occurs, it is always between two FortiGate units, but you can configure any FortiGate unit to perform WAN optimization with any of the other FortiGate units that are part of your WAN.

WAN optimization among multiple networks

You can also configure WAN optimization between FortiGate units with different roles on the WAN. FortiGate units configured as security devices and for WAN optimization can perform WAN optimization as if they are single-purpose FortiGate units just configured for WAN optimization.

WAN optimization with web caching

You can add web caching to a WAN optimization topology when users on a private network communicate with web servers located across the WAN on another private network.

WAN optimization with web caching topology

The topology above is the same as that shown in [WAN optimization with web caching on page 761](#) with the addition of web caching to the FortiGate unit in front of the private network that includes the web servers. You can also add web caching to the FortiGate unit that is protecting the private network. In a similar way, you can add web caching to any WAN Optimization topology.

Explicit web proxy topologies

You can configure a FortiGate unit to be an explicit web proxy server for Internet web browsing of IPv4 and IPv6 web traffic. To use the explicit web proxy, users must add the IP address of the FortiGate interface configured for the explicit web proxy to their web browser proxy configuration.

Explicit web proxy topology

If the FortiGate unit supports web caching, you can also add web caching to the security policy that accepts explicit web proxy sessions. The FortiGate unit then caches Internet web pages on a hard disk to improve web browsing performance.

Explicit web proxy with web caching topology

Explicit FTP proxy topologies

You can configure a FortiGate unit to be an explicit FTP proxy server for FTP users. To use the explicit web proxy, FTP users must connect to and authenticate with the explicit FTP proxy before connecting to an FTP server.

Explicit FTP proxy topology

You can also configure reverse explicit FTP proxy. In this configuration, users on the Internet connect to the explicit web proxy before connecting to an FTP server installed behind a FortiGate unit.

Reverse explicit FTP proxy topology

Web caching topologies

FortiGate web caching can be added to any security policy and any HTTP or HTTPS traffic accepted by that security policy can be cached on the FortiGate unit hard disk. This includes WAN optimization and explicit web proxy traffic. The network topologies for these scenarios are very similar. They involved a FortiGate unit installed between users and web servers with web caching enabled.

A typical web-caching topology includes one FortiGate unit that acts as a web cache server. Web caching is enabled in a security policy and the FortiGate unit intercepts web page requests accepted by the security policy, requests web pages from the web servers, caches the web page contents, and returns the web page contents to the users. When the FortiGate unit intercepts subsequent requests for cached web pages, the FortiGate unit contacts the destination web server just to check for changes.

Web caching topology

You can also configure reverse proxy web-caching. In this configuration, users on the Internet browse to a web server installed behind a FortiGate unit. The FortiGate unit intercepts the web traffic (HTTP and HTTPS) and caches pages from the web server. Reverse proxy web caching on the FortiGate unit reduces the number of requests that the web server must handle, leaving it free to process new requests that it has not serviced before.

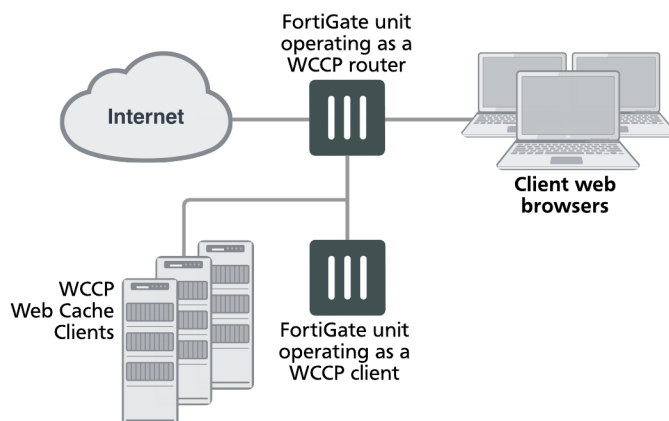

Reverse proxy web caching topology

WCCP topologies

You can operate a FortiGate unit as a Web Cache Communication Protocol (WCCP) router or cache engine. As a router, the FortiGate unit intercepts web browsing requests from client web browsers and forwards them to a WCCP cache engine. The cache engine returns the required cached content to the client web browser. If the cache server does not have the required content it accesses the content, caches it and returns the content to the client web browser.

WCCP topology

FortiGate units can also operate as WCCP cache servers, communicating with WCCP routers, caching web content and providing it to client web browsers as required.

WCCP is transparent to client web browsers. The web browsers do not have to be configured to use a web proxy.

Inside FortiOS: WAN optimization

Enterprises deploying FortiOS can leverage WAN optimization to provide fast and secure application responses between locations on a Wide Area Network (WAN). The web caching component of FortiOS WAN optimization extends this protection and performance boost to cloud services.

Centralize without compromising your WAN performance

Many multi-location enterprise environments reduce costs and consolidate resources by centralizing applications or providing applications in the cloud. Efficient and high-speed communication between applications and their users is critical. Remote sites don't always have access to high bandwidth, but users at all sites expect consistent network performance. Minimizing user impact and improving performance is especially vital when applications designed for local area networks (LANs) are on the cloud.

Even applications that work fine on a local LAN, such as Windows File Sharing (CIFS), email exchange (MAPI), and many others, suffer from bandwidth limitations and latency issues when accessed over a WAN. This results in a loss of productivity and a perceived need for expensive network upgrades. FortiOS's WAN Optimization provides an inexpensive and easy way to deploy a solution to this problem.

FortiOS is commonly deployed in central offices, satellite offices, and in the cloud to provide secure communications across a WAN using IPsec or SSL VPN. This installed infrastructure can be leveraged to add more value by using WAN Optimization to accelerate WAN traffic and web caching to accelerate cloud services.

FortiOS WAN optimization

FortiOS includes license-free WAN optimization on most current FortiGate devices. WAN optimization is a comprehensive solution that maximizes your WAN performance and provides intelligent bandwidth management and unmatched consolidated security performance. WAN optimization reduces your network overhead and removes unnecessary traffic for a better overall performance experience. Efficient use of bandwidth and better application performance will remove the need for costly WAN link upgrades between data centers and other expensive solutions for your network traffic growth.

Protocol optimization

Protocol optimization is effective for applications designed for the LAN that do not function well on low bandwidth high latency networks. FortiOS protocol optimization improves the efficiency of CIFS, FTP, HTTP, MAPI, and general TCP sessions.

Regular bandwidth usage**Improved bandwidth usage with FortiGate protocol optimization**

For example, CIFS, which is a fairly “chatty” protocol, requires many background transactions to successfully transfer a single file. When transferring the file, CIFS sends small chunks of data and waits sequentially for each chunk’s arrival and acknowledgment before sending the next. This large amount of request/acknowledgement traffic can delay transfers. FortiOS CIFS WAN Optimization removes this chattiness and gets on with the job of transferring the file.

TCP protocol optimization uses techniques such as SACK support, window scaling and window size adjustment, and connection pooling to remove common WAN TCP bottlenecks.

Web caching

In an enterprise environment, multiple users will often want to get the same content (for example, a sales spreadsheet, a corporate presentation or a PDF from a cloud service, or a software update). With FortiOS Web caching, content from the cloud, from the web or from other sites on the WAN is download once and cached on the local FortiGate device. When other users access the same content they download it from the cache. The result is less bandwidth use and reduced latency for the file requester.

FortiOS web caching also recognizes requests for Windows or MS-Office updates and downloads the new update file in the background. Once downloaded to the cache, the new update file is available to all users and all subsequent requests for this update are rapidly downloaded from the cache.

Byte caching

Byte caching improves caching by accelerating the transfer of similar, but not identical content. Byte caching accelerates multiple downloads of different email messages with the same corporate disclaimer by downloading the disclaimer over the WAN once and then downloading all subsequent disclaimers from a local FortiGate unit. Byte caching reduces the amount of data crossing the WAN when multiple different emails with the same or similar attachments or different versions of an attachment are downloaded from a corporate email server to different locations over the WAN.

Dynamic data chunking

Dynamic data chunking detects and optimizes persistent data chunks in changed files or in data embedded in traffic that uses an unknown protocol. For example, dynamic chunking can cache data in Lotus notes traffic and make the data chunks available for email and other protocols.

Data deduplication

Byte caching breaks large units of application data, like an email attachment or a file download, into manageable small chunks of data. Each chunk of data is labeled with a hash, and chunks with their respective hashes are stored in a database on the local FortiGate unit. When a remote user request a file, the WAN Optimization sends the hashes, rather than the actual data. The FortiGate unit at the other end of the WAN tunnel reassembles the data from its own hash database, only downloading chunks that it is missing. Deduplication, or the process of eliminating duplicate data, will reduce space consumption. In addition to reducing the amount of data downloaded across the WAN, byte caching is not application specific and assists by accelerating all of the protocols supported by WAN Optimization.

Server monitoring and management

The health and performance of real servers can be monitored from the FortiGate GUI. Virtual servers and their assigned real servers can be monitored for health status, if there have been any monitor events, number of active sessions, round trip time and number of bytes processed. Should a server become problematic and require administration, it can be gracefully removed from the Real Server pool to enable disruption free maintenance. When a removed real server is able to operate it can gracefully be added back to the virtual server.

SSL acceleration

SSL is used by many organizations to keep WAN communications private. WAN Optimization boosts SSL acceleration properties of FortiGate FortiASIC hardware by accelerating SSL traffic across the WAN. The FortiGate unit handles SSL encryption/decryption for corporate servers providing SSL encrypted connections over the WAN.

VPN replacement

FortiOS WAN optimization supports secure SSL-encrypted tunnels between FortiGate units on the WAN. Employing secure WAN Optimization tunnels can replace IPsec VPNs between sites. The result is a single, relatively simple configuration that supports optimization and privacy of communication across the WAN and uses FortiGate SSL acceleration to provide high performance.

Road warriors and home workers

The drive to give employees greater flexibility and reduce operational costs has led to more remote workers, both at home and on the road. Whether accessing the office from a hotel, public wireless hotspot, or home, the problem is the same: low bandwidth and high latency harming application performance. WAN Optimization is integrated into FortiClient, which can be installed on PCs and wireless devices to optimize communication between remote workers and their offices.

Reduce your...

- **Capital outlay:** Organizations only need to purchase a single device per location.
- **Licensing costs:** WAN Optimization is included with FortiOS. Additional licenses are not needed.
- **Network complexity:** Small offices that may not have the space or power connections for multiple devices do not need to worry: no additional devices are required.

WAN optimization concepts

Client/server architecture

Traffic across a WAN typically consists of clients on a client network communicating across a WAN with a remote server network. The clients do this by starting communication sessions from the client network to the server network. These communication sessions can be open text over the WAN or they can be encrypted by SSL VPN or IPsec VPN.

To optimize these sessions, you can add **WAN optimization security policies** to the **client-side FortiGate unit** to accept sessions from the client network that are destined for the server network. The client-side FortiGate unit is located between the client network and the WAN. WAN optimization security policies include **WAN optimization profiles** that control how the traffic is optimized.

The client-side FortiGate unit must also include the IP address of the **server-side FortiGate unit** in its WAN optimization **peer** configuration. The server-side FortiGate unit is located between the server network and the WAN. The peer configuration allows the client-side FortiGate unit to find the server-side FortiGate unit and attempt to establish a WAN optimization **tunnel** with it.

For the server-side FortiGate unit you must add a security policy with **wanopt** as the **Incoming Interface**. This security policy allows the FortiGate unit to accept WAN optimization sessions from the client-side FortiGate unit. For the server-side FortiGate unit to accept a WAN optimization connection it must have the client-side FortiGate unit in its WAN optimization peer configuration.

WAN optimization profiles are only added to the client-side WAN optimization security policy. The server-side FortiGate unit employs the WAN optimization settings set in the WAN optimization profile on the client-side FortiGate unit.

Client/server architecture

When both peers are identified the FortiGate units attempt to establish a WAN optimization **tunnel** between them. WAN optimization tunnels use port 7810. All optimized data flowing across the WAN between the client-side and server-side FortiGate units use this tunnel. WAN optimization tunnels can be encrypted using SSL encryption to keep the data in the tunnel secure.

Any traffic can be sent through a WAN optimization tunnel. This includes SSL and IPsec VPN traffic. However, instead of configuring SSL or IPsec VPN for this communication you can add SSL encryption using the WAN optimization tunnel.

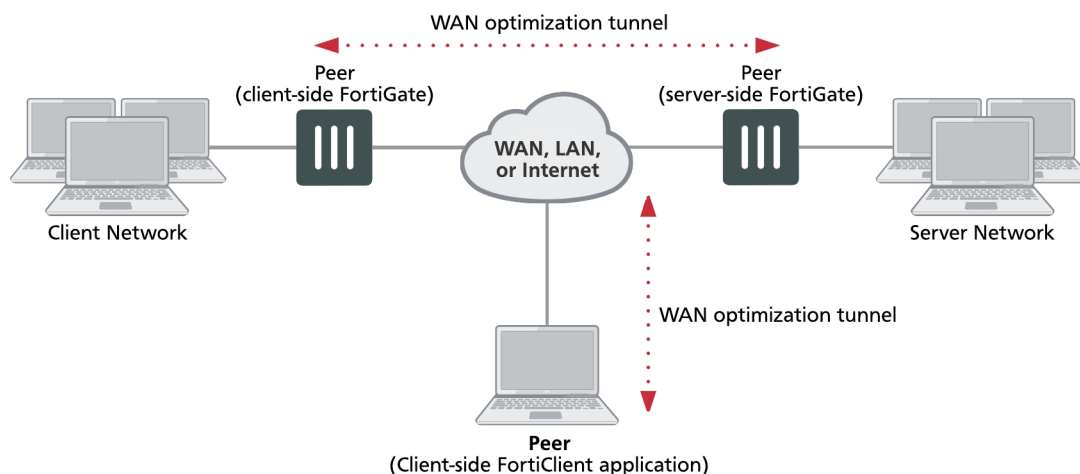

In addition to basic identification by peer host ID and IP address you can configure WAN optimization **authentication** using certificates and pre-shared keys to improve security. You can also configure FortiGate units involved in WAN optimization to accept connections from any identified peer or restrict connections to specific peers.

The FortiClient application can act in the same manner as a client-side FortiGate unit to optimize traffic between a computer running FortiClient and a FortiGate unit.

WAN optimization peers

The client-side and server-side FortiGate units are called WAN optimization peers because all of the FortiGate units in a WAN optimization network have the same peer relationship with each other. The client and server roles just relate to how a session is started. Any FortiGate unit configured for WAN optimization can be a client-side and a server-side FortiGate unit at the same time, depending on the direction of the traffic. Client-side FortiGate units initiate WAN optimization sessions and server-side FortiGate units respond to the session requests. Any FortiGate unit can simultaneously be a client-side FortiGate unit for some sessions and a server-side FortiGate unit for others.

WAN optimization peer and tunnel architecture

To identify all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with, you add host IDs and IP addresses of all of the peers to the FortiGate unit configuration. The peer IP address is actually the IP address of the peer unit interface that communicates with the FortiGate unit.

Protocol optimization

Protocol optimization techniques optimize bandwidth use across the WAN. These techniques can improve the efficiency of communication across the WAN optimization tunnel by reducing the amount of traffic required by communication protocols. You can apply protocol optimization to Common Internet File System (CIFS), FTP, HTTP, MAPI, and general TCP sessions. You can apply general TCP optimization to MAPI sessions.

For example, CIFS provides file access, record locking, read/write privileges, change notification, server name resolution, request batching, and server authentication. CIFS is a fairly “chatty” protocol, requiring many background transactions to successfully transfer a single file. This is usually not a problem across a LAN. However, across a WAN, latency and bandwidth reduction can slow down CIFS performance.

When you select the CIFS protocol in a WAN optimization profile, the FortiGate units at both ends of the WAN optimization tunnel use a number of techniques to reduce the number of background transactions that occur over the WAN for CIFS traffic.

If a policy accepts a range of different types of traffic, you can set **Protocol** to **TCP** to apply general optimization techniques to TCP traffic. However, applying this TCP optimization is not as effective as applying more protocol-specific optimization to specific types of traffic. TCP protocol optimization uses techniques such as TCP SACK support, TCP window scaling and window size adjustment, and TCP connection pooling to remove TCP bottlenecks.

Protocol optimization and MAPI

By default the MAPI service uses port number 135 for RPC port mapping and may use random ports for MAPI messages. The random ports are negotiated through sessions using port 135. The FortiOS DCE-RPC session helper learns these ports and opens pinholes for the messages. WAN optimization is also aware of these ports and attempts to apply protocol optimization to MAPI messages that use them. However, to configure protocol optimization for MAPI you should set the WAN optimization profile to a single port number (usually port 135). Specifying a range of ports may reduce performance.

Byte caching

Byte caching breaks large units of application data (for example, a file being downloaded from a web page) into small chunks of data, labeling each chunk of data with a hash of the chunk and storing those chunks and their hashes in a database. The database is stored on a WAN optimization storage device. Then, instead of sending the actual data over the WAN tunnel, the FortiGate unit sends the hashes. The FortiGate unit at the other end of the tunnel receives the hashes and compares them with the hashes in its local byte caching database. If any hashes match, that data does not have to be transmitted over the WAN optimization tunnel. The data for any hashes that does not match is transferred over the tunnel and added to that byte caching database. Then the unit of application data (the file being downloaded) is reassembled and sent to its destination.

The stored byte caches are not application specific. Byte caches from a file in an email can be used to optimize downloading that same file or a similar file from a web page.

The result is less data transmitted over the WAN. Initially, byte caching may reduce performance until a large enough byte caching database is built up.

To enable byte caching, you select **Byte Caching** in a WAN optimization profile.

Byte caching cannot determine whether or not a file is compressed (for example a zip file), and caches compressed and non-compressed versions of the same file separately.

Dynamic data chunking for byte caching

Dynamic data chunking can improve byte caching by improving detection of data chunks that are already cached in changed files or in data embedded in traffic using an unknown protocol. Dynamic data chunking is available for HTTP, CIFS and FTP.

Use the following command to enable dynamic data chunking for HTTP in the default WAN optimization profile.

```
config wanopt profile
  edit default
    config http
      set prefer-chunking dynamic
    end
```

By default dynamic data chunking is disabled and `prefer-chunking` is set to `fix`.

WAN optimization transparent mode

WAN optimization is transparent to users. This means that with WAN optimization in place, clients connect to servers in the same way as they would without WAN optimization. However, servers receiving packets after WAN optimization “see” different source addresses depending on whether or not transparent mode is selected for WAN optimization. If transparent mode is selected, WAN optimization keeps the original source address of the packets, so servers appear to receive traffic directly from clients. Routing on the server network should be configured to route traffic with client source IP addresses from the server-side FortiGate unit to the server and back to the server-side FortiGate unit.

Some protocols, for example CIFS, may not function as expected if transparent mode is **not** selected. In most cases, for CIFS WAN optimization you should select transparent mode and make sure the server network can route traffic as described to support transparent mode.

If transparent mode is not selected, the source address of the packets received by servers is changed to the address of the server-side FortiGate unit interface that sends the packets to the servers. So servers appear to receive packets from the server-side FortiGate unit. Routing on the server network is simpler in this case because client addresses are not involved. All traffic appears to come from the server-side FortiGate unit and not from individual clients.

Do not confuse WAN optimization transparent mode with FortiGate transparent mode. WAN optimization transparent mode is similar to source NAT. FortiGate's transparent mode is a system setting that controls how the FortiGate unit (or a VDOM) processes traffic.

Configuring transparent mode

You can configure transparent mode by selecting **Transparent** in a WAN Optimization profile. The profile is added to an active WAN Optimization policy.

When you configure a passive WAN Optimization policy you can accept the active policy transparent setting or you can override the active policy transparent setting. From the GUI you can do this by setting the **Passive Option** as follows:

- **default** use the transparent setting in the WAN Optimization profile added to the active policy (client-side configuration).
- **transparent** impose transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate keep their original source addresses.
- **non-transparent** impose non-transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate have their source address changed to the address of the server-side FortiGate unit interface that sends the packets to the servers.

From the CLI you can use the following command:

```
config firewall policy
    set wanopt-passive-opt {default | transparent | non-transparent}
end
```

Operating modes and VDOMs

To use WAN optimization, the FortiGate units can operate in either NAT/Route or transparent mode. The client-side and server-side FortiGate units do not have to be operating in the same mode.

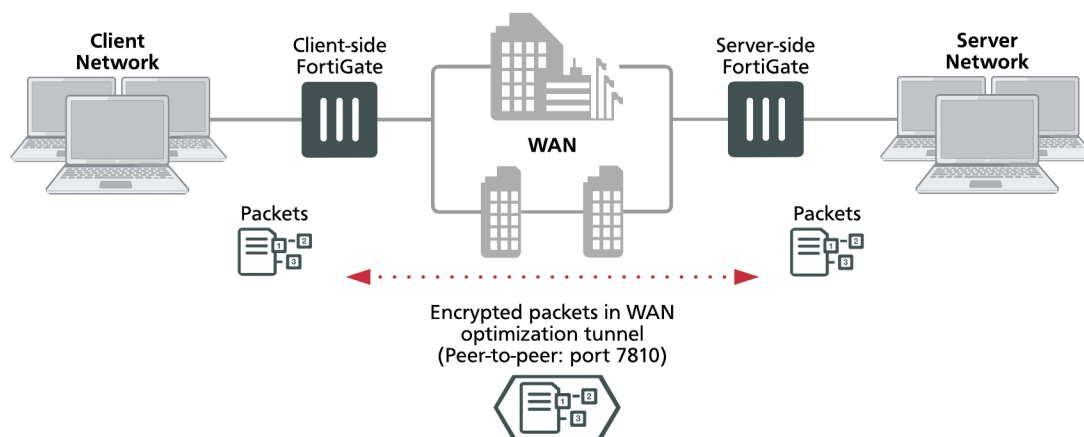

As well, the FortiGate units can be configured for multiple virtual domain (VDOM) operation. You configure WAN optimization for each VDOM and configure one or both of the units to operate with multiple VDOMs enabled.

If a FortiGate unit or VDOM is operating in transparent mode with WAN optimization enabled, WAN optimization uses the management IP address as the peer IP address of the FortiGate unit instead of the address of an interface.

WAN optimization tunnels

All optimized traffic passes between the FortiGate units over a WAN optimization tunnel. Traffic in the tunnel can be sent in plain text or encrypted using AES-128bit-CBC SSL.

WAN optimization tunnels

Both plain text and the encrypted tunnels use TCP destination port 7810.

Before a tunnel can be started, the peers must be configured to authenticate with each other. Then, the client-side peer attempts to start a WAN optimization tunnel with the server-side peer. Once the peers authenticate with each other, they bring up the tunnel and WAN optimization communication over the tunnel starts. After a tunnel has been established, multiple WAN optimization sessions can start and stop between peers without restarting the tunnel.

Tunnel sharing

You can use the `tunnel-sharing` WAN optimization profile CLI keyword to configure tunnel sharing for WAN optimization rules. Tunnel sharing means multiple WAN optimization sessions share the same tunnel. Tunnel sharing can improve performance by reducing the number of WAN optimization tunnels between FortiGate units. Having fewer tunnels means less data to manage. Also, tunnel setup requires more than one exchange of information between the ends of the tunnel. Once the tunnel is set up, each new session that shares the tunnel avoids tunnel setup delays.

Tunnel sharing also uses bandwidth more efficiently by reducing the chances that small packets will be sent down the tunnel. Processing small packets reduces network throughput, so reducing the number of small packets

improves performance. A shared tunnel can combine all the data from the sessions being processed by the tunnel and send the data together. For example, suppose a FortiGate unit is processing five WAN optimization sessions and each session has 100 bytes to send. If these sessions use a shared tunnel, WAN optimization combines the packets from all five sessions into one 500-byte packet. If each session uses its own private tunnel, five 100-byte packets will be sent instead. Each packet also requires a TCP ACK reply. The combined packet in the shared tunnel requires one TCP ACK packet. The separate packets in the private tunnels require five.

Use the following command to configure tunnel sharing for HTTP traffic in a WAN optimization profile.

```
config wanopt profile
  edit default
    config http
      set tunnel-sharing {express-shared | private | shared}
    end
```

Tunnel sharing is not always recommended and may not always be the best practice. Aggressive and non-aggressive protocols should not share the same tunnel. An aggressive protocol can be defined as a protocol that is able to get more bandwidth than a non-aggressive protocol. (The aggressive protocols can “starve” the non-aggressive protocols.) HTTP and FTP are considered aggressive protocols. If aggressive and non-aggressive protocols share the same tunnel, the aggressive protocols may take all of the available bandwidth. As a result, the performance of less aggressive protocols could be reduced. To avoid this problem, rules for HTTP and FTP traffic should have their own tunnel. To do this, set `tunnel-sharing` to `private` for WAN optimization rules that accept HTTP or FTP traffic.

It is also useful to set `tunnel-sharing` to `express-shared` for applications, such as Telnet, that are very interactive but not aggressive. Express sharing optimizes tunnel sharing for Telnet and other interactive applications where latency or delays would seriously affect the user’s experience with the protocol.

Set `tunnel-sharing` to `shared` for applications that are not aggressive and are not sensitive to latency or delays. WAN optimization rules set to `sharing` and `express-shared` can share the same tunnel.

WAN optimization and user and device identity policies, load balancing and traffic shaping

Please note the following about WAN optimization and firewall policies:

- WAN optimization is not compatible with firewall load balancing.
- WAN optimization is compatible with source and destination NAT options in firewall policies (including firewall virtual IPs). If a virtual IP is added to a policy the traffic that exits the WAN optimization tunnel has its destination address changed to the virtual IPs mapped to IP address and port.
- WAN optimization is compatible with user identity-based and device identity security policies. If a session is allowed after authentication or device identification the session can be optimized.

Traffic shaping

Traffic shaping works for WAN optimization traffic that is not in a WAN optimization tunnel. So traffic accepted by a WAN optimization security policy on a client-side FortiGate unit can be shaped on ingress. However, when the traffic enters the WAN optimization tunnel, traffic shaping is not applied.

In manual mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- Traffic shaping cannot be applied to traffic on the server-side FortiGate unit.

In active-passive mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- If transparent mode is enabled in the WAN optimization profile, traffic shaping also works as expected on the server-side FortiGate unit.
- If transparent mode is not enabled, traffic shaping works partially on the server-side FortiGate unit.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended best practice HA configuration for WAN optimization is active-passive mode. When the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

You can also form a WAN optimization tunnel between a cluster and a standalone FortiGate unit or between two clusters.

In a cluster, only the primary unit stores the byte cache database. This database is not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its byte cache. Rebuilding the byte cache can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate unit that it is participating with in WAN optimization tunnels.

WAN optimization, web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency FortiOS WAN optimization uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, WAN optimization requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When WAN optimization is enabled you will see a reduction in available memory. The reduction increases when more WAN optimization sessions are being processed. If you are thinking of enabling WAN optimization on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by WAN optimization. See "get test {wad | wccpd} <test_level>" for more information.

WAN optimization configuration

This chapter describes FortiGate WAN optimization client server architecture and other concepts you need to understand to be able to configure FortiGate WAN optimization.

Manual (peer-to-peer) and active-passive WAN optimization

You can create **manual** (peer-to-peer) and **active-passive** WAN optimization configurations.

In reality, because WAN optimization traffic can only be processed by one CPU core, it is not recommended to increase the number of manual mode peers on the FortiGate unit per VDOM.

Note that the maximum number of manual peers are restricted to 256 per VDOM. However, in Active-Passive configurations, there is no hard-limit to the maximum number of manual peers per VDOM.

Manual (peer to peer) configurations

Manual configurations allow for WAN optimization between one client-side FortiGate unit and one server-side FortiGate unit. To create a manual configuration you add a **manual mode** WAN optimization security policy to the client-side FortiGate unit. The manual mode policy includes the peer ID of a server-side FortiGate unit.

In a manual mode configuration, the client-side peer can only connect to the named server-side peer. When the client-side peer initiates a tunnel with the server-side peer, the packets that initiate the tunnel include extra information so that the server-side peer can determine that it is a peer-to-peer tunnel request. This extra information is required because the server-side peer does not require a WAN optimization policy; however, you need to add the client peer host ID and IP address to the server-side FortiGate unit peer list.

In addition, from the server-side FortiGate unit CLI you must add an Explicit Proxy security policy with `proxy` set to `wanopt` and the destination interface and network set to the network containing the servers that clients connect to over the WAN optimization tunnel. WAN optimization tunnel requests are accepted by the explicit proxy policy and if the client-side peer is in the server side peer's address list the traffic is forwarded to the servers on the destination network.

Manual mode client-side policy

You must configure manual mode client-side policies from the CLI. From the GUI a manual mode policy has WAN Optimization turned on and includes the following text beside the *WAN optimization* field: *Manual (Profile: <profile-name>. Peer: <peer-name>.*

Add a manual mode policy to the client-side FortiGate unit from the CLI. The policy enables WAN optimization, sets `wanopt-detection` to `off`, and uses the `wanopt-peer` option to specify the server-side peer. The following example uses the default WAN optimization profile.

```
config firewall policy
  edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr client-subnet
    set dstaddr server-subnet
```

```

        set action accept
        set schedule always
        set service ALL
        set wanopt enable
        set wanopt-detection off
        set wanopt-profile default
        set wanopt-peer server
    next
end

```

Manual mode server-side explicit proxy policy

The server-side explicit proxy policy allows connections from the WAN optimization tunnel to the server network by setting the proxy type to `wanopt`. You must add policies that set `proxy` to `wanopt` from the CLI and these policies do not appear on the GUI. The policy should look like the following:

```

configure firewall proxy-policy
edit 3
    set proxy wanopt
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
next
end

```

Active-passive configurations

Active-passive WAN optimization requires an **active** WAN optimization policy on the client-side FortiGate unit and a **passive** WAN optimization policy on the server-side FortiGate unit. The server-side FortiGate unit also requires an explicit proxy policy with `proxy` set to `wanopt`.

You can use the passive policy to control WAN optimization address translation by specifying **transparent mode** or non-transparent mode. See [Manual \(peer-to-peer\) and active-passive WAN optimization on page 776](#). You can also use the passive policy to apply security profiles, web caching, and other FortiGate features at the server-side FortiGate unit. For example, if a server-side FortiGate unit is protecting a web server, the passive policy could enable web caching.

A single passive policy can accept tunnel requests from multiple FortiGate units as long as the server-side FortiGate unit includes their peer IDs and all of the client-side FortiGate units include the server-side peer ID.

Active client-side policy

Add an active policy to the client-side FortiGate unit by turning on **WAN Optimization** and selecting **active**. Then select a WAN optimization **Profile**. From the CLI the policy could look like the following:

```

config firewall policy
edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr client-subnet
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL

```

```
        set wanopt enable
        set wanopt-detection active
        set wanopt-profile default
    next
end
```

Server-side tunnel policy

The server-side requires an explicit proxy policy that sets the `proxy` to `wanopt`. You must add this policy from the CLI and policies with `proxy` set to `wanopt` do not appear on the GUI. From the CLI the policy could look like the following:

```
configure firewall proxy-policy
edit 3
    set proxy wanopt
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
next
end
```

Server-side passive policy

Add a passive policy to the server-side FortiGate unit by selecting **Enable WAN Optimization** and selecting **passive**. Then set the **Passive Option** to **transparent**. From the CLI the policy could look like the following:

```
config firewall policy
edit 2
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set wanopt enable
    set wanopt-detection passive
    set wanopt-passive-opt transparent
next
```

WAN optimization profiles

Use WAN optimization profiles to apply WAN optimization techniques to traffic to be optimized. In a WAN optimization profile you can select the protocols to be optimized and for each protocol you can enable SSL offloading (if supported), secure tunneling, byte caching and set the port or port range the protocol uses. You can also enable transparent mode and optionally select an authentication group. You can edit the default WAN optimization profile or create new ones.

To configure a WAN optimization profile go to **WAN Opt. & Cache > Profiles** and edit a profile or create a new one.

Configuring a WAN optimization profile

Edit WAN Optimization Profile

default WANopt profile

22/255

☒ Transparent Mode

☒ Authentication Group

Auth-Grp

Protocol	SSL Offloading	Secure Tunneling	Byte Caching	Port
<input checked="" type="checkbox"/> CIFS		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	445
<input checked="" type="checkbox"/> FTP		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	21
<input checked="" type="checkbox"/> HTTP	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	80
<input checked="" type="checkbox"/> MAPI		<input type="checkbox"/>	<input checked="" type="checkbox"/>	135
<input checked="" type="checkbox"/> TCP	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1-65535

From the CLI you can use the following command to configure a WAN optimization profile to optimize HTTP traffic.

```
config wanopt profile
  edit new-profile
    config http
      set status enable
  end
```

Transparent Mode

Servers receiving packets after WAN optimization “see” different source addresses depending on whether or not you select **Transparent Mode**.

For more information, see [WAN optimization profiles on page 778](#).

Authentication Group

Select this option and select an authentication group so that the client and server-side FortiGate units must authenticate with each other before starting the WAN optimization tunnel. You must also select an authentication group if you select **Secure Tunneling** for any protocol.

You must add identical authentication groups to both of the FortiGate units that will participate in the WAN optimization tunnel. For more information, see [Configuring authentication groups on page 1](#).

Protocol

Select CIFS, FTP, HTTP or MAPI to apply protocol optimization for the selected protocols. See [WAN optimization profiles on page 778](#).

Select TCP if the WAN optimization tunnel accepts sessions that use more than one protocol or that do not use the CIFS, FTP, HTTP, or MAPI protocol.

SSL Offloading	<p>Select to apply SSL offloading for HTTPS or other SSL traffic. You can use SSL offloading to offload SSL encryption and decryption from one or more HTTP servers to the FortiGate unit. If you enable this option, you must configure the security policy to accept SSL-encrypted traffic.</p> <p>If you enable SSL offloading, you must also use the CLI command <code>config firewall ssl-server</code> to add an SSL server for each HTTP server that you want to offload SSL encryption/decryption for. For more information, see Turning on web caching for HTTPS traffic on page 1.</p>
Secure Tunneling	<p>The WAN optimization tunnel is encrypted using SSL encryption. You must also add an authentication group to the profile. For more information, see Secure tunneling on page 1.</p>
Byte Caching	<p>Select to apply WAN optimization byte caching to the sessions accepted by this rule. For more information, see "Byte caching".</p>
Port	<p>Enter a single port number or port number range. Only packets whose destination port number matches this port number or port number range will be optimized.</p>

Processing non-HTTP sessions accepted by a WAN optimization profile with HTTP optimization

From the CLI, you can use the following command to configure how to process non-HTTP sessions when a rule configured to accept and optimize HTTP traffic accepts a non-HTTP session. This can occur if an application sends non-HTTP sessions using an HTTP destination port.

```
config wanopt profile
  edit default
    config http
      set status enable
      set tunnel-non-http {disable | enable}
    end
```

To drop non-HTTP sessions accepted by the rule set `tunnel-non-http` to `disable`, or set it to `enable` to pass non-HTTP sessions through the tunnel without applying protocol optimization, byte-caching, or web caching. In this case, the FortiGate unit applies TCP protocol optimization to non-HTTP sessions.

Processing unknown HTTP sessions

Unknown HTTP sessions are HTTP sessions that do not comply with HTTP 0.9, 1.0, or 1.1. From the CLI, use the following command to specify how a rule handles such HTTP sessions.

```
config wanopt profile
  edit default
    config http
      set status enable
      set unknown-http-version {best-effort | reject | tunnel}
    end
```

To assume that all HTTP sessions accepted by the rule comply with HTTP 0.9, 1.0, or 1.1, select `best-effort`. If a session uses a different HTTP version, WAN optimization may not parse it correctly. As a result, the

FortiGate unit may stop forwarding the session and the connection may be lost. To reject HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, select `reject`.

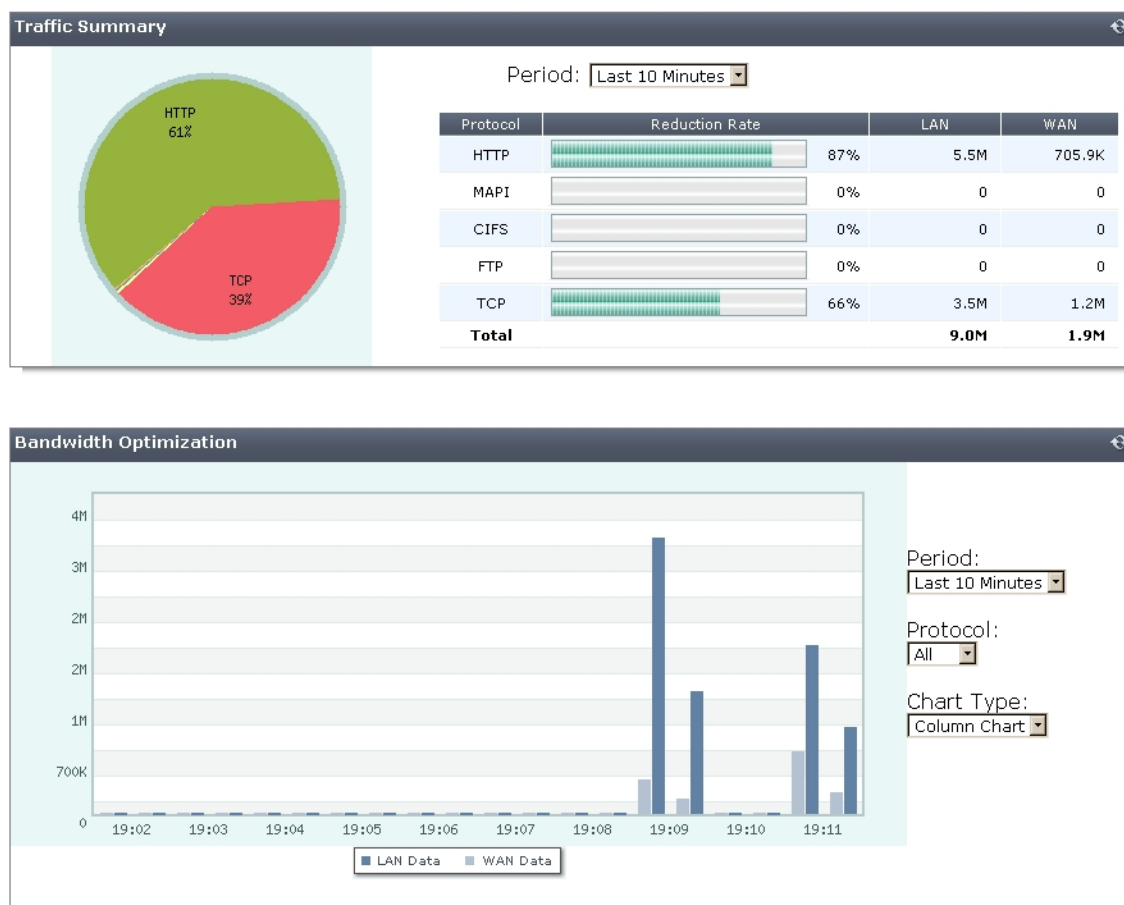

To pass HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, but without applying HTTP protocol optimization, byte-caching, or web caching, you can also select `tunnel`. TCP protocol optimization is applied to these HTTP sessions.

Monitoring WAN optimization performance

Using WAN optimization monitoring, you can confirm that a FortiGate unit is optimizing traffic and view estimates of the amount of bandwidth saved. The WAN optimization monitor presents collected log information in a graphical format to show network traffic summary and bandwidth optimization information.

To view the WAN optimization monitor, go to **Monitor > WAN Opt. Monitor**.

WAN optimization monitor

Traffic summary

The traffic summary shows how WAN optimization is reducing the amount of traffic on the WAN for each WAN optimization protocol by showing the traffic reduction rate as a percentage of the total traffic. The traffic summary also shows the amount of WAN and LAN traffic. If WAN optimization is being effective the amount of WAN traffic should be lower than the amount of LAN traffic.

You can use the refresh icon to update the traffic summary display at any time. You can also set the amount of time for which the traffic summary shows data. The time period can vary from the last 10 minutes to the last month.

Bandwidth optimization

This section shows network bandwidth optimization per time period. A line or column chart compares an application's pre-optimized size (LAN data) with its optimized size (WAN data). You can select the chart type, the monitoring time period, and the protocol for which to display data. If WAN optimization is being effective the WAN bandwidth should be lower than the LAN bandwidth.

WAN optimization configuration summary

This section includes a client-side and a server-side WAN Optimization configuration summary.:

Client-side configuration summary

Local host ID and peer settings

```

config wanopt settings
    set host-id client
end
config wanopt peer
    edit server
        set ip 10.10.2.82
    end

```

Security policies

Two client-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on the client-side

```

config firewall policy
    edit 2
        set srcintf internal
        set dstintf wan1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set wanopt enable <<< enable WAN optimization
        set wanopt-detection active <<< set the mode to active/passive
        set wanopt-profile "default" <<< select the wanopt profile
    next
end

```

Manual mode on the client-side

```

config firewall policy
    edit 2
        set srcintf internal
        set dstintf wan1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set wanopt enable <<< enable WAN optimization
        set wanopt-detection off <<< sets the mode to manual
        set wanopt-profile "default" <<< select the wanopt profile
    next
end

```

```

        set wanopt-peer "server" <<< set the only peer to do wanopt
                                with
                                (required for manual mode)
    next
end

```

server-side configuration summary

Local host ID and peer settings

```

config wanopt settings
    set host-id server
end
config wanopt peer
    edit client
        set ip 10.10.2.81
    end
end

```

Security policies

Two server-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on server-side

```

config firewall policy
edit 2 <<< the passive mode policy
    set srcintf wan1
    set dstintf internal
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
    set wanopt enable
    set wanopt-detection passive
    set wanopt-passive-opt transparent
end
config firewall proxy-policy
    edit 3 <<< policy that accepts wanopt tunnel connections from the server
        set proxy wanopt <<< wanopt proxy type
        set dstintf internal
        set srcaddr all
        set dstaddr server-subnet
        set action accept
        set schedule always
        set service ALL
    next
end

```

Manual mode on server-side

```

config firewall proxy-policy
    edit 3 <<< policy that accepts wanopt tunnel connections from the client
        set proxy wanopt <<< wanopt proxy type
        set dstintf internal
        set srcaddr all
    end
end

```

```
        set dstaddr server-subnet
        set action accept
        set schedule always
        set service ALL
    next
end
```

WANopt storage

The `config wanopt storage` option has been combined with `config system storage`.

Setting the disk-usage mode is no longer in `config system global`. It is set through `config system storage`.

Syntax:

```
config system storage
    edit <name-string>
        set status enable
        set media-status
        set order
        set partition
        set device
        set size
        set usage
        set wanopt-mode
```

Option	Description
status	Enable/disable storage
media-status	Enable/disable the physical status of current media
order	Set storage order
partition	Label of underlying partition Example: "MIXEDXXE2946380"
device	Partition device. Example: "/dev/vdb1"
size	Partition size. Example: 8616
usage	Use hard disk for logging and WAN Optimization.

Option	Description
	WAN Optimization mode
wanopt-mode	<ul style="list-style-type: none"> • <code>mix</code> - default, recommended • <code>wanopt</code> - recommended if only wanopt feature is enabled • <code>webcache</code> - recommended if only webcache feature is enabled <p>If only one of the two features is being used, using the applicable recommended mode will give a higher cache capacity and improve performance.</p>

WANOpt cache service

The `config wanopt cache-service` command is used to configure `cache-service` clusters between multiple FortiGates. The result is that the `cache-service` daemons of the different FortiGates can collaborate together for serving web cache entries.

To configure the wanopt cache-service

```
config wanopt cache-service
  set prefer-scenario
  set collaboration
  set device-id
  set acceptable-connections
  config dst-peer
    edit <dst-peer-name>
      set auth-type
      set encode-type
      set priority
      set ip
  config src-peer
    edit <src-peer>
      set auth-type
      set encode-type
      set priority
      set ip
```

Option	Description
prefer-scenario	<p>Set the preferred cache behavior to the appropriate balance between latency and hit ratio</p> <p>Options:</p> <ul style="list-style-type: none"> • <code>balance</code> - Balance between speed and cache hit ratio. • <code>prefer-speed</code> - Prefer response speed at the expense of increased cache bypasses. • <code>prefer-cache</code> - Prefer improving hit-ratio through increasing latency tolerance.

Option	Description
collaboration	enable/disable cache collaboration between cache-service clusters
device-id	Set identifier for this cache device
acceptable-connections	Set strategy when accepting cache collaboration connection Options: <ul style="list-style-type: none"> any - The cache-service can accept any cache collaboration connection. peers - The cache-service will only accept connections that are already in src-peers.
auth-type	Set authentication type for this peer Value is integer from 0 to 255
encode-type	Set encode type for this peer Value is integer from 0 to 255
priority	Set priority for this peer Value is integer from 0 to 255. Default = 1
ip	Set cluster IP address of this peer

Video caching

This config wanopt content-delivery-network-rule command configures web-caching including the video-cache matching rules.

To configure the wanopt content-delivery-network-rule

```

config wanopt content-delivery-network-rule
  edit <content_rule_name>
    set comment
    set status
    set host-domain-name-suffix
    set category
    set request-cache-control
    set response-cache-control
    set response-expires
    set text-response-vcache
    set updateserver
    config rules
      edit <rule_name>
        set match-mode
        set skip-rule-mode
        config match-entries
          edit <integer>

```

```

set target
set pattern
config skip-entries
set target
set pattern
config content id
set target
set start-str
set start-skip
set start-direction
set end-str
set end-skip
set end-direction
set range-str

```

Option	Description
comment	Comment about this rule
status	Enable/disable WAN optimization content delivery network rules
host-domain-name-suffix	Suffix portion of the fully qualified domain name (eg. fortinet.com in "www.fortinet.com")
category	Content delivery network rule category
request-cache-control	Enable/disable HTTP request cache control
response-cache-control	Enable/disable HTTP response cache control
response-expires	Enable/disable HTTP response cache expires
updateserver	Enable/disable update server
match-mode	Match criteria for collecting content ID
skip-rule-mode	Skip mode when evaluating skip rules
target	Option in HTTP header or URL parameter to match
pattern	Pattern string for matching target (Referrer or URL pattern, eg. "a", "a*c", "**a*", "a*c*e", and "**")
start-str	String from which to start search
start-skip	Number of characters in URL to skip after <code>start-str</code> has been matched
start-direction	Search direction from <code>start-str</code> match

Option	Description
<code>end-str</code>	String from which to end search
<code>end-skip</code>	Number of characters in URL to skip after end-str has been matched
<code>end-direction</code>	Search direction from <code>end-str</code> match
<code>range-str</code>	Name of content ID within the start string and end string

Best practices

This is a short list of WAN optimization and explicit proxy best practices.

- WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic. However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel. See [Best practices on page 789](#).
- Active-passive HA is the recommended HA configuration for WAN optimization. See [Best practices on page 789](#).
- Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure. See [Accepting any peers on page 1](#).
- Set the explicit proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit web proxy. See [General explicit web proxy configuration steps on page 1](#).
- Set the explicit FTP proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit FTP proxy. See [General explicit FTP proxy configuration steps on page 1](#).
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy. See [General explicit web proxy configuration steps on page 1](#).

Example basic manual (peer-to-peer) WAN optimization configuration

In a manual (peer to peer) configuration the WAN optimization tunnel can be set up between one client-side FortiGate unit and one server-side FortiGate unit. The peer ID of the server-side FortiGate unit is added to the client-side WAN optimization policy. When the client-side FortiGate unit initiates a tunnel with the server-side FortiGate unit, the packets that initiate the tunnel include information that allows the server-side FortiGate unit to determine that it is a manual tunnel request. The server-side FortiGate unit does not require a WAN optimization profile; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list and from the CLI an explicit proxy policy to accept WAN optimization tunnel connections.

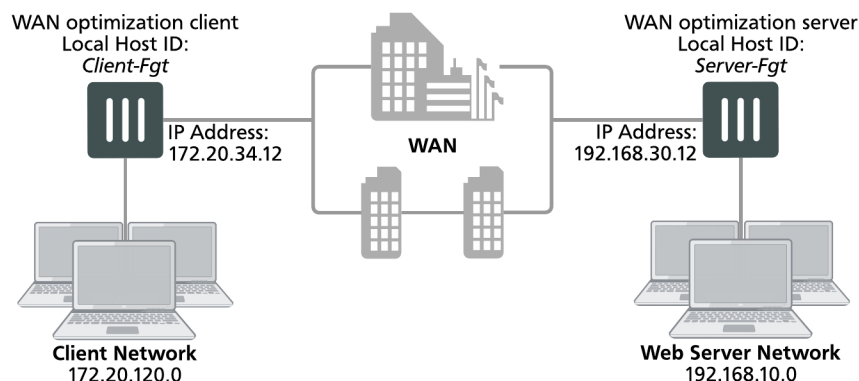

In a manual WAN optimization configuration, you create a manual WAN optimization security policy on the client-side FortiGate unit. To do this you must use the CLI to set `wanopt-detection` to `off` and to add the peer host ID of the server-side FortiGate unit to the WAN optimization security policy.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-Fgt with a WAN IP address of 172.20.34.12. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Server_Fgt with a WAN IP address of 192.168.30.12. This unit is in front of a web server network with IP address 192.168.10.0.

This example customizes the default WAN optimization profile on the client-side FortiGate unit and adds it to the WAN optimization policy. You can also create a new WAN optimization profile.

Example manual (peer-to-peer) topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
 - Add peers.
 - Configure the default WAN optimization profile to optimize HTTP traffic.
 - Add a manual WAN optimization security policy.
2. Configure the server-side FortiGate unit:
 - Add peers.
 - Add a WAN optimization tunnel policy.

Configuring basic peer-to-peer WAN optimization - web-based manager

Use the following steps to configure the example configuration from the web-based manager.

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add the server-side FortiGate unit **Peer Host ID** and **IP Address** for the server-side FortiGate:

Peer Host ID	Server-Fgt
IP Address	192.168.30.12

4. Select **OK**.
5. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

6. Select **Create New** to add a firewall address for the web server network.

Category	Address
Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Go to **WAN Opt. & Cache > Profiles** and edit the default profile.
8. Select **Transparent Mode**.
9. Under Protocol, select **HTTP** and for HTTP select **Byte Caching**. Leave the HTTP **Port** set to 80.
10. Select **Apply** to save your changes.
11. Go to **Policy & Objects > IPv4 Policy** and add a WAN optimization security policy to the client-side FortiGate unit that accepts traffic to be optimized:

Incoming Interface	port1
Source Address	all
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

12. Select **Enable WAN Optimization** and configure the following settings:

Enable WAN Optimization	active
Profile	default

13. Select **OK**.
14. Edit the policy from the CLI to turn off `wanopt-detection`, add the peer ID of the server-side FortiGate unit, and the default WAN optimization profile. The following example assumes the ID of the policy is 5:

```
config firewall policy
edit 5
    set wanopt-detection off
    set wanopt-peer Server-Fgt
    set wanopt-profile default
end
```

When you set the detection mode to `off` the policy becomes a manual mode WAN optimization policy. On the web-based manager the WAN optimization part of the policy changes to the following:

Enable WAN Optimization	Manual (Profile: default, Peer: Peer-Fgt-2)
--------------------------------	---

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.20.34.12

4. Select **OK**.
5. Enter the following CLI command to add an explicit proxy policy to accept WAN optimization tunnel connections.

```
configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end
```

Configuring basic peer-to-peer WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
    set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server-Fgt
    set ip 192.168.30.12
  end
```

3. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
    set type ipmask
    set subnet 172.20.120.0 255.255.255.0
    set associated-interface port1
  end
```

4. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
    set type ipmask
    set subnet 192.168.10.0 255.255.255.0
    set associated-interface port2
  end
```

5. Edit the default WAN optimization profile, select transparent mode, enable HTTP WAN optimization and enable byte caching for HTTP. Leave the HTTP Port set to 80.

```
config wanopt profile
  edit default
    set transparent enable
    config http
      set status enable
      set byte-caching enable
    end
  end
```

6. Add a WAN optimization security policy to the client-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set service ALL
    set schedule always
    set wanopt enable
    set wanopt-profile default
    set wanopt-detection off
    set wanopt-peer Server-Fgt
  end
```

To configure the server-side FortiGate unit**1. Add the Local Host ID to the server-side FortiGate configuration:**

```
config wanopt settings
  set host-id Server-Fgt
```

```
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit Client-Fgt
    set ip 192.168.30.12
  end
```

3. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
  edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
  next
end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example `http://192.168.10.100`. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the client-side FortiGate unit is accepting traffic for the 192.168.10.0 network. You can do this by checking the policy monitor (**Monitor > Firewall User Monitor**). Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating.

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output for the client-side FortiGate unit shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
vd=0 shared=no uses=0 state=3
peer name=Web-servers id=100 ip=192.168.30.12
```

```
SSL-secured-tunnel=no auth-grp=
bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual
vd=0 shared=no uses=0 state=3
peer name=Web-servers id=99 ip=192.168.30.12
SSL-secured-tunnel=no auth-grp=
bytes_in=348 bytes_out=384

Tunnel: id=98 type=manual
vd=0 shared=no uses=0 state=3

Example active-passive WAN optimization

In active-passive WAN optimization you add an active WAN optimization policy to the client-side FortiGate unit and you add a WAN optimization tunnel policy and a passive WAN optimization policy to the server-side FortiGate unit.

The active policy accepts the traffic to be optimized and sends it down the WAN optimization tunnel to the server-side FortiGate unit. The active policy can also apply security profiles and other features to traffic before it exits the client-side FortiGate unit.

A tunnel explicit proxy policy on the server-side FortiGate unit allows the server-side FortiGate unit to form a WAN optimization tunnel with the client-side FortiGate unit. The passive WAN optimization policy is required because of the active policy on the client-side FortiGate unit. You can also use the passive policy to apply WAN optimization transparent mode and features such as security profiles, logging, traffic shaping and web caching to the traffic before it exits the server-side FortiGate unit.

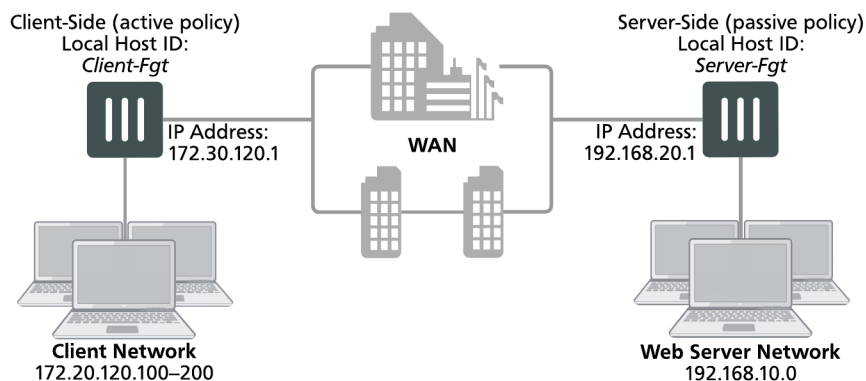

Network topology and assumptions

On the client-side FortiGate unit this example configuration includes a WAN optimization profile that optimizes CIFS, HTTP, and FTP traffic and an active WAN optimization policy. The active policy also applies virus scanning to the WAN optimization traffic.

On the server-side FortiGate unit, the passive policy applies application control to the WAN optimization traffic.

In this example, WAN optimization transparent mode is selected in the WAN optimization profile and the passive WAN optimization policy accepts this transparent mode setting. This means that the optimized packets maintain their original source and destination addresses. As a result, routing on the client network must be configured to route packets for the server network to the client-side FortiGate unit. Also the routing configuration on the server network must be able to route packets for the client network to the server-side FortiGate unit.

Example active-passive WAN optimization topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:

- Add peers.
 - Add a WAN optimization profile to optimize CIFS, FTP, and HTTP traffic.
 - Add firewall addresses for the client and web server networks.
 - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit by:
 - Add peers.
 - Add firewall addresses for the client and web server networks.
 - Add a passive WAN optimization policy.
 - Add a WAN optimization tunnel policy.

Configuring basic active-passive WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager.

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add a Peer Host ID and the **IP Address** for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Profiles** and select **Create New** to add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic:

Name	Custom-wan-opt-pro
Transparent Mode	Select

6. Select the **CIFS** protocol, select **Byte Caching** and set the **Port** to 445.
7. Select the **FTP** protocol, select **Byte Caching** and set the **Port** to 21.
8. Select the **HTTP** protocol, select **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range

Subnet / IP Range	172.20.120.100-172.20.120.200
Interface	port1

11. Select **Create New** to add an address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

Incoming Interface	port1
Source Address	Client-Net
Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP FTP SMB
Action	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	active
Profile	Custom-wan-opt-pro

14. Turn on Antivirus and select the **default** antivirus profile.
15. Select **OK**.

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select **OK**.
5. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range
Subnet / IP Range	172.20.120.100-172.20.120.200
Interface	port1

6. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Select **OK**.
8. Select **Policy & Objects > IPv4 Policy** and select **Create New** to add a passive WAN optimization policy that applies application control.

Incoming Interface	port2
Source Address	Client-Net
Outgoing Interface	port1
Destination Address	Web-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

9. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	passive
Passive Option	default

10. Select **OK**.

11. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end
```

Configuring basic active-passive WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
    set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
    edit Server-Fgt
        set ip 192.168.20.1
    end
end
```

3. Add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic.

```
config wanopt profile
    edit Custom-wan-opt-pro
        config cifs
            set status enable
            set byte-caching enable
            set port 445
        end
        config http
            set status enable
            set byte-caching enable
            set port 80
        end
        config ftp
            set status enable
            set byte-caching enable
            set port 21
        end
    end
end
```

4. Add a firewall address for the client network.

```
config firewall address
    edit Client-Net
        set type iprange
        set start-ip 172.20.120.100
        set end-ip 172.20.120.200
    end
end
```

```

        set associated-interface port1
    end

```

5. Add a firewall address for the web server network.

```

config firewall address
    edit Web-Server-Net
        set type ipmask
        set subnet 192.168.10.0 255.255.255.0
        set associated-interface port2
    end

```

6. Add an active WAN optimization security policy that applies virus scanning:

```

config firewall policy
    edit 0
        set srcintf port1
        set dstintf port2
        set srcaddr Client-net
        set dstaddr Web-Server-Net
        set action accept
        set service HTTP FTP SMB
        set schedule always
        set wanopt enable
        set wanopt-detection active
        set wanopt-profile Custom-wan-opt-pro
    end

```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```

config wanopt settings
    set host-id Server-Fgt
end

```

2. Add the client-side Local Host ID to the server-side peer list:

```

config wanopt peer
    edit Client-Fgt
        set ip 172.20.120.1
    end

```

3. Add a firewall address for the client network.

```

config firewall address
    edit Client-Net
        set type iprange
        set start-ip 172.20.120.100
        set end-ip 172.20.120.200
        set associated-interface port1
    end

```

4. Add a firewall address for the web server network.

```

config firewall address
    edit Web-Server-Net
        set type ipmask
        set subnet 192.168.10.0 255.255.255.0
        set associated-interface port2
    end

```

5. Add a passive WAN optimization policy.

```

config firewall policy
    edit 0
        set srcintf port1
        set dstintf port2

```

```

        set srcaddr Client-Net
        set dstaddr Web-Server-Net
        set action accept
        set service ALL
        set schedule always
        set wanopt enable
        set wanopt-detection passive
        set wanopt-passive-opt default
    end

```

6. Add a WAN optimization tunnel explicit proxy policy.

```

configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end

```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example `http://192.168.10.100`. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include security profiles. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 3 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to on).

```

diagnose wad tunnel list

Tunnel: id=139 type=auto

```

```

vd=0 shared=no uses=0 state=1
peer name= id=0 ip=unknown
SSL-secured-tunnel=no auth-grp=test

Tunnels total=3 manual=0 auto=3

```

Example adding secure tunneling to an active-passive WAN optimization configuration

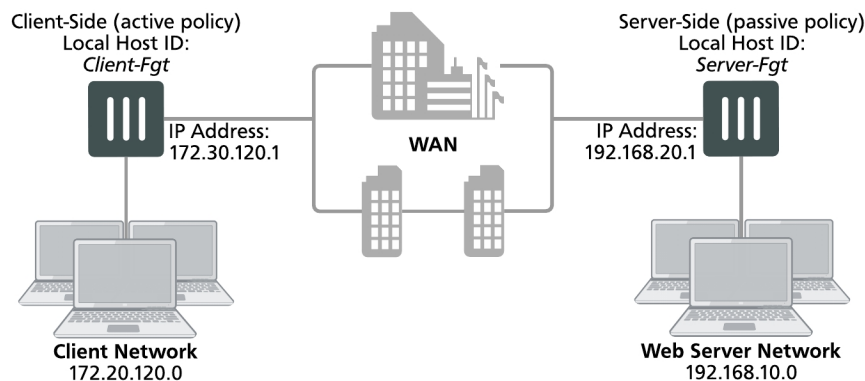

This example shows how to configure two FortiGate units for active-passive WAN optimization with secure tunneling. The same authentication group is added to both FortiGate units. The authentication group includes a password (or pre-shared key) and has **Peer Acceptance** set to **Accept any Peer**. An active policy is added to the client-side FortiGate unit and a passive policy to the server-side FortiGate unit. The active policy includes a profile that performs secure tunneling, optimizes HTTP traffic, and uses transparent mode and byte caching.

The authentication group is named **Auth-Secure-Tunnel** and the password for the pre-shared key is **2345678**. The topology for this example is shown below. This example includes web-based manager configuration steps followed by equivalent CLI configuration steps. For information about secure tunneling, see [Secure tunneling on page 1](#).

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-net with a WAN IP address of 172.30.120.1. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Web-servers and has a WAN IP address of 192.168.20.1. This unit is in front of a web server network with IP address 192.168.10.0.

Example active-passive WAN optimization and secure tunneling topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
 - Add peers.
 - Add an authentication group.
 - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit.
 - Add peers.
 - Add the same authentication group
 - Add a passive WAN optimization policy that applies application control.
 - Add a WAN optimization tunnel policy.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring WAN optimization with secure tunneling - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt
----------------------	------------

2. Select **Apply** to save your setting.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** to add the authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select **OK**.
7. Go to **WAN Opt. & Cache > Profiles** and select **Create New** to add a WAN optimization profile that enables secure tunneling and includes the authentication group:

Name	Secure-wan-op-pro
Transparent Mode	Select
Authentication Group	Auth-Secure-tunnel

8. Select the **HTTP** protocol, select Secure Tunneling and **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

11. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

Incoming Interface	port1
Source Address	Client-Net
Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP
Action	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	active
Profile	Secure-wan-opt-pro

14. Select **OK**.

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt
----------------------	------------

2. Select **Apply** to save your setting.
 3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select **OK**.
 5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** and add an authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select **OK**.
 7. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

8. Select **Create New** to add a firewall address for the web server network.

Category	Address
-----------------	---------

Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

9. Select **OK**.
10. Select **Create New** to add a passive WAN optimization policy that applies application control.

Incoming Interface	port2
Source Address	Client-Net
Outgoing Interface	port1
Destination Address	Web-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

11. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	passive
Passive Option	default

12. Select **OK**.
13. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
end
```

Configuring WAN optimization with secure tunneling - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
```

```
set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
edit Server-Fgt
set ip 192.168.20.1
end
```

3. Add a new authentication group to be used for secure tunneling:

```
config wanopt auth-group
edit Auth-Secure-Tunnel
set auth-method psk
set psk 2345678
end
```

Leave peer-accept at its default value.

4. Add a WAN optimization profile that enables secure tunneling and includes the authentication group, enables HTTP protocol optimization, and enables secure tunneling and byte caching for HTTP traffic:

```
config wanopt profile
edit Secure-wan-op-pro
set auth-group Auth-Secure-Tunnel
config http
set status enable
set secure-tunnel enable
set byte-caching enable
set port 80
end
end
```

5. Add a firewall address for the client network.

```
config firewall address
edit Client-Net
set type ipmask
set subnet 172.20.120.0 255.255.255.0
set associated-interface port1
end
```

6. Add a firewall address for the web server network.

```
config firewall address
edit Web-Server-Net
set type ipmask
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

7. Add an active WAN optimization security policy that includes the WAN optimization profile that enables secure tunneling and that applies virus scanning:

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service HTTP
```

```
set schedule always
set wanopt enable
set wanopt-detection active
set wanopt-profile Secure-wan-opt-pro
end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
edit Client-Fgt
set ip 172.20.120.1
end
```

3. Add an authentication group to be used for secure tunneling:

```
config wanopt auth-group
edit Auth-Secure-Tunnel
set auth-method psk
set psk 2345678
end
```

Leave `peer-accept` at its default value.

4. Add a firewall address for the client network.

```
config firewall address
edit Client-Net
set type ipmask
set subnet 172.20.120.0 255.255.255.0
set associated-interface port1
end
```

5. Add a firewall address for the web server network.

```
config firewall address
edit Web-Server-Net
set type ipmask
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

6. Add a passive WAN optimization policy.

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service ALL
set schedule always
set wanopt enable
set wanopt-detection passive
```

```
    set wanopt-passive-opt default
end
```

7. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end
```

Peers and authentication groups

All communication between WAN optimization peers begins with one WAN optimization peer (or client-side FortiGate unit) sending a WAN optimization tunnel request to another peer (or server-side FortiGate unit). During this process, the WAN optimization peers identify and optionally authenticate each other.

Basic WAN optimization peer requirements

WAN optimization requires the following configuration on each peer. For information about configuring local and peer host IDs, see [Basic WAN optimization peer requirements on page 811](#).

- The peer must have a unique host ID.
- Unless authentication groups are used, peers authenticate each other using host ID values. Do not leave the local host ID at its default value.
- The peer must know the host IDs and IP addresses of all of the other peers that it can start WAN optimization tunnels with. This does not apply if you use authentication groups that accept all peers.
- All peers must have the same local certificate installed on their FortiGate units if the units authenticate by local certificate. Similarly, if the units authenticate by pre-shared key (password), administrators must know the password. The type of authentication is selected in the authentication group. This applies only if you use authentication groups.

Accepting any peers

Strictly speaking, you do not need to add peers. Instead you can configure authentication groups that accept any peer. However, for this to work, both peers must have the same authentication group (with the same name) and both peers must have the same certificate or pre-shared key.

Accepting any peer is useful if you have many peers or if peer IP addresses change. For example, you could have FortiGate units with dynamic external IP addresses (using DHCP or PPPoE). For most other situations, this method is not recommended and is not a best practice as it is less secure than accepting defined peers or a single peer. For more information, see [Basic WAN optimization peer requirements on page 811](#).

How FortiGate units process tunnel requests for peer authentication

When a client-side FortiGate unit attempts to start a WAN optimization tunnel with a peer server-side FortiGate unit, the tunnel request includes the following information:

- the client-side local host ID
- the name of an authentication group, if included in the rule that initiates the tunnel
- if an authentication group is used, the authentication method it specifies: pre-shared key or certificate
- the type of tunnel (secure or not).

For information about configuring the local host ID, peers and authentication groups, see [How FortiGate units process tunnel requests for peer authentication on page 811](#) and [How FortiGate units process tunnel requests for peer authentication on page 811](#).

The authentication group is optional unless the tunnel is a secure tunnel. For more information, see [How FortiGate units process tunnel requests for peer authentication on page 811](#).

If the tunnel request includes an authentication group, the authentication will be based on the settings of this group as follows:

- The server-side FortiGate unit searches its own configuration for the name of the authentication group in the tunnel request. If no match is found, the authentication fails.
- If a match is found, the server-side FortiGate unit compares the authentication method in the client and server authentication groups. If the methods do not match, the authentication fails.
- If the authentication methods match, the server-side FortiGate unit tests the peer acceptance settings in its copy of the authentication group.
- If the setting is **Accept Any Peer**, the authentication is successful.
- If the setting is **Specify Peer**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the peer name in the server-side authentication group. If the names match, authentication is successful. If a match is not found, authentication fails.
- If the setting is **Accept Defined Peers**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the server-side peer list. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the tunnel request does not include an authentication group, authentication will be based on the client-side local host ID in the tunnel request. The server-side FortiGate unit searches its peer list to match the client-side local host ID in the tunnel request. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the server-side FortiGate unit successfully authenticates the tunnel request, the server-side FortiGate unit sends back a tunnel setup response message. This message includes the server-side local host ID and the authentication group that matches the one in the tunnel request.

The client-side FortiGate unit then performs the same authentication procedure as the server-side FortiGate unit did. If both sides succeed, tunnel setup continues.

Configuring peers

When you configure peers, you first need to add the local host ID that identifies the FortiGate unit for WAN optimization and then add the peer host ID and IP address of each FortiGate unit with which a FortiGate unit can create WAN optimization tunnels.

To configure WAN optimization peers - web-based manager:

1. Go to **WAN Opt. & Cache > Peers**.
2. For **Local Host ID**, enter the local host ID of **this** FortiGate unit and select **Apply**. If you add this FortiGate unit as a peer to another FortiGate unit, use this ID as its **peer** host ID.

The local or host ID can contain up to 25 characters and can include spaces.

3. Select **Create New** to add a new peer.
4. For **Peer Host ID**, enter the peer host ID of the peer FortiGate unit. This is the local host ID added to the peer FortiGate unit.
5. For **IP Address**, add the IP address of the peer FortiGate unit. This is the source IP address of tunnel requests sent by the peer, usually the IP address of the FortiGate interface connected to the WAN.
6. Select **OK**.

To configure WAN optimization peers - CLI:

In this example, the local host ID is named `HQ_Peer` and has an IP address of `172.20.120.100`. Three peers are added, but you can add any number of peers that are on the WAN.

1. Enter the following command to set the local host ID to `HQ_Peer`.

```
config wanopt settings
  set host-id HQ_peer
end
```

2. Enter the following commands to add three peers.

```
config wanopt peer
  edit Wan_opt_peer_1
    set ip 172.20.120.100
  next
  edit Wan_opt_peer_2
    set ip 172.30.120.100
  next
  edit Wan_opt_peer_3
    set ip 172.40.120.100
end
```

Configuring authentication groups

You need to add authentication groups to support authentication and secure tunneling between WAN optimization peers.

To perform authentication, WAN optimization peers use a certificate or a pre-shared key added to an authentication group so they can identify each other before forming a WAN optimization tunnel. Both peers must have an authentication group with the same name and settings. You add the authentication group to a peer-to-peer or active rule on the client-side FortiGate unit. When the server-side FortiGate unit receives a tunnel start request from the client-side FortiGate unit that includes an authentication group, the server-side FortiGate unit finds an authentication group in its configuration with the same name. If both authentication groups have the same certificate or pre-shared key, the peers can authenticate and set up the tunnel.

Authentication groups are also required for secure tunneling.

To add authentication groups, go to **WAN Opt. & Cache > Authentication Groups**.

To add an authentication group - web-based manager:

Use the following steps to add any kind of authentication group. It is assumed that if you are using a local certificate to authenticate, it is already added to the FortiGate unit

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New**.
3. Add a **Name** for the authentication group.

You will select this name when you add the authentication group to a WAN optimization rule.

4. Select the **Authentication Method**.

Select **Certificate** if you want to use a certificate to authenticate and encrypt WAN optimization tunnels. You must select a local certificate that has been added to this FortiGate unit. (To add a local certificate, go to **System > Certificates**.) Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and certificate.

Select **Pre-shared key** if you want to use a pre-shared key or password to authenticate and encrypt WAN optimization tunnels. You must add the **Password** (or pre-shared key) used by the authentication group. Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and password. The password must contain at least 6 printable characters and should be known only by network administrators. For optimum protection against currently known attacks, the key should consist of a minimum of 16 randomly chosen alphanumeric characters.

5. Configure **Peer Acceptance** for the authentication group.

Select **Accept Any Peer** if you do not know the peer host IDs or IP addresses of the peers that will use this authentication group. This setting is most often used with FortiGate units that do not have static IP addresses, for example units that use DHCP.

Select **Accept Defined Peers** if you want to authenticate with peers added to the peer list only.

Select **Specify Peer** and select one of the peers added to the peer list to authenticate with the selected peer only.

6. Select **OK**.

7. Add the authentication group to a WAN optimization rule to apply the authentication settings in the authentication group to the rule.

To add an authentication group that uses a certificate- CLI:

Enter the following command to add an authentication group that uses a certificate and can authenticate all peers added to the FortiGate unit configuration.

In this example, the authentication group is named `auth_grp_1` and uses a certificate named `Example_Cert`.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert Example_Cert
    set peer-accept defined
  end
```

To add an authentication group that uses a pre-shared key - CLI:

Enter the following command to add an authentication group that uses a pre-shared key and can authenticate only the peer added to the authentication group.

In this example, the authentication group is named `auth_peer`, the peer that the group can authenticate is named `Server_net`, and the authentication group uses `123456` as the pre-shared key. In practice you should use a more secure pre-shared key.

```
config wanopt auth-group
  edit auth_peer
    set auth-method psk
    set psk 123456
    set peer-accept one
    set peer Server_net
  end
```

To add an authentication group that accepts WAN optimization connections from any peer - web-based manager

Add an authentication group that accepts any peer for situations where you do not have the **Peer Host IDs** or **IP Addresses** of the peers that you want to perform WAN optimization with. This setting is most often used for WAN optimization with FortiGate units that do not have static IP addresses, for example units that use DHCP. An authentication group that accepts any peer is less secure than an authentication group that accepts defined peers or a single peer.

The example below sets the authentication method to **Pre-shared key**. You must add the same password to all FortiGate units using this authentication group.

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New** to add a new authentication group.
3. Configure the authentication group:

Name	Specify any name.
Authentication Method	Pre-shared key
Password	Enter a pre-shared key.
Peer Acceptance	Accept Any Peer

To add an authentication group that accepts WAN optimization connections from any peer - CLI:

In this example, the authentication group is named `auth_grp_1`. It uses a certificate named `WAN_Cert` and accepts any peer.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert WAN_Cert
    set peer-accept any
  end
```

Secure tunneling

You can configure WAN optimization rules to use AES-128bit-CBC SSL to encrypt the traffic in the WAN optimization tunnel. WAN optimization uses FortiASIC acceleration to accelerate SSL decryption and encryption of the secure tunnel. Peer-to-peer secure tunnels use the same TCP port as non-secure peer-to-peer tunnels (TCP port 7810).

To use secure tunneling, you must select **Enable Secure Tunnel** in a WAN optimization rule and add an authentication group. The authentication group specifies the certificate or pre-shared key used to set up the secure tunnel. The **Peer Acceptance** setting of the authentication group does not affect secure tunneling.

The FortiGate units at each end of the secure tunnel must have the same authentication group with the same name and the same configuration, including the same pre-shared key or certificate. To use certificates you must install the same certificate on both FortiGate units.

For active-passive WAN optimization you can select **Enable Secure Tunnel** only in the active rule. In peer-to-peer WAN optimization you select **Enable Secure Tunnel** in the WAN optimization rule on both FortiGate units.

For information about active-passive and peer-to-peer WAN optimization, see [Manual \(peer-to-peer\) and active-passive WAN optimization on page 1](#)

For a secure tunneling configuration example, see [Example: Adding secure tunneling to an active-passive WAN optimization configuration on page 1](#).

Monitoring WAN optimization peer performance

The WAN optimization peer monitor lists all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with. These include peers manually added to the configuration as well as discovered peers.

The monitor lists each peer's name, IP address, and peer type. The peer type indicates whether the peer was manually added or discovered. To show WAN optimization performance, for each peer the monitor lists the percent of traffic reduced by the peer in client-side WAN optimization configurations and in server-side configurations (also called gateway configurations).

To view the peer monitor, go to **WAN Opt. & Cache > Peer Monitor**.

Web cache concepts

FortiGate web caching is a form of object caching that accelerates web applications and web servers by reducing bandwidth usage, server load, and perceived latency. Web caching supports caching of HTTP 1.0 and HTTP 1.1 web sites. See [RFC 2616](#) for information about web caching for HTTP 1.1.

Web caching supports caching of Flash content over HTTP but does not cache audio and video streams including Flash videos and streaming content that use native streaming protocols such as RTMP.

The first time a file is received by web caching it is cached in the format it is received in, whether it be compressed or uncompressed. When the same file is requested by a client but in a different compression format, the cached file is converted to the new compressed format before being sent to the client.

There are three significant advantages to using web caching to improve HTTP and WAN performance:

- reduced bandwidth consumption because fewer requests and responses go over the WAN or Internet.
- reduced web server load because there are fewer requests for web servers to handle.
- reduced latency because responses for cached requests are available from a local FortiGate unit instead of from across the WAN or Internet.

You can use web caching to cache any web traffic that passes through the FortiGate unit, including web pages from web servers on a LAN, WAN or on the Internet. You apply web caching by enabling the web caching option in any security policy. When enabled in a security policy, web caching is applied to all HTTP sessions accepted by the security policy. If the security policy is an explicit web proxy security policy, the FortiGate unit caches explicit web proxy sessions.

Turning on web caching for HTTP and HTTPS traffic

Web caching can be applied to any HTTP or HTTPS traffic by enabling web caching in a security policy that accepts the traffic. This includes IPv4, IPv6, WAN optimization and explicit web proxy traffic. Web caching caches all HTTP traffic accepted by a policy on TCP port 80.

You can add web caching to a policy to:

- Cache Internet HTTP traffic for users on an internal network to reduce Internet bandwidth use. Do this by selecting the web cache option for security policies that allow users on the internal network to browse web sites on the Internet.
- Reduce the load on a public facing web server by caching objects on the FortiGate unit. This is a reverse proxy with web caching configuration. Do this by selecting the web cache option for a security policy that allows users on the Internet to connect to the web server.
- Cache outgoing explicit web proxy traffic when the explicit proxy is used to proxy users in an internal network who are connecting to the web servers on the Internet. Do this by selecting the web cache option for explicit web proxy security policies that allow users on the internal network to browse web sites on the Internet.
- Combine web caching with WAN optimization. You can enable web caching in any WAN optimization security policy. This includes manual, active, and passive WAN optimization policies and WAN optimization tunnel policies. You can enable web caching on both the client-side and the server-side FortiGate units or on just one or the other.

For optimum performance you can enable web caching on both the client-side and server-side FortiGate units. In this way only uncached content is transmitted through the WAN optimization tunnel. All cached content is access locally by clients from the client side FortiGate unit.

One important use for web caching is to cache software updates (for example, Windows Updates or iOS updates). When updates occur a large number of users may all be trying to download these updates at the same time. Caching these updates will be a major performance improvement and also have a potentially large impact on reducing Internet bandwidth use. You may want to adjust the maximum cache object size to make sure these updates are cached. See [Turning on web caching for HTTP and HTTPS traffic on page 817](#).

Turning on web caching for HTTPS traffic

Web caching can also cache the content of HTTPS traffic on TCP port 443. With HTTPS web caching, the FortiGate unit receives the HTTPS traffic on behalf of the client, opens up the encrypted traffic and extracts content to be cached. Then FortiGate unit re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack.

You enable HTTPS web caching from the CLI in a security policy or an explicit proxy policy that accepts the traffic to be cached using `webcache-https`. For a firewall policy:

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https enable
    .
    .
    .
  end
```

For an explicit web proxy policy:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    .
    .
    .
    set webcache enable
    set webcache-https enable
    .
    .
    .
  end
```

The `webcache-https` field is available only if `webcache` is enabled.

Web caching for HTTPS traffic is not supported if WAN optimization or FTP proxy is enabled: i.e., if `srcintf` is `ftp-proxy` or `wanopt`.

The `any` setting causes the FortiGate unit to re-encrypt the traffic with the FortiGate unit's certificate rather than the original certificate. This configuration can cause errors for HTTPS clients because the name on the certificate does not match the name on the web site.

You can stop these errors from happening by configuring HTTPS web caching to use the web server's certificate by setting `webcache-https` to `ssl-server`. This option is available for both firewall policies and explicit web proxy policies.

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https enable
    .
    .
    .
  end
```

The `ssl-server` option causes the FortiGate unit to re-encrypt the traffic with a certificate that you imported into the FortiGate unit. You can add certificates using the following command:

```
config firewall ssl-server
  edit corporate-server
    set ip <Web-Server-IP>
    set port 443
    set ssl-mode { full | half}
    set ssl-cert <Web-Server-Cert>
  end
```

Where:

`Web-Server-IP` is the web server's IP address.

`Web-Server-Cert` is a web server certificate imported into the FortiGate unit.

The SSL server configuration also determines whether the SSL server is operating in half or full mode and the port used for the HTTPS traffic.

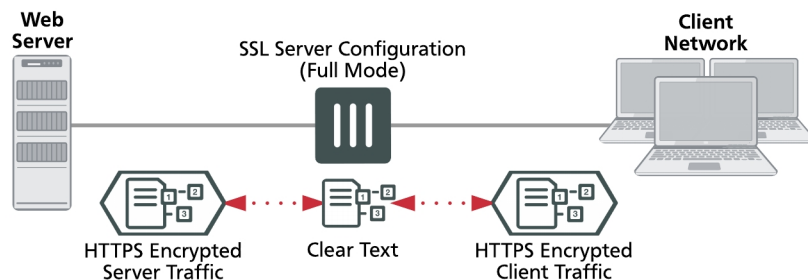

You can add multiple SSL server certificates in this way. When web caching processing an SSL stream if it can find a certificate that matches the web server IP address and port of one of the added SSL servers; that certificate is used to encrypt the SSL traffic before sending it to the client. As a result the client does not generate SSL certificate errors.

Web caching uses the FortiGate unit's FortiASIC to accelerate SSL decryption/encryption performance.

Full mode SSL server configuration

The `ssl-mode` option determines whether the SSL server operates in half or full mode. In full mode the FortiGate unit performs both decryption and encryption of the HTTPS traffic. The full mode sequence is shown below.

Full mode SSL server configuration

In full mode the FortiGate unit is acting as a man in the middle, decrypting and encrypting the traffic. So both the client and the web server see encrypted packets.

Usually the port of the encrypted HTTPS traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. This port is not altered by the SSL Server. So for example, if the SSL Server receives HTTPS traffic on port 443, the re-encrypted traffic forwarded to the FortiGate unit to the server or client will still use port 443.

Half mode SSL server configuration

In half mode, the FortiGate unit only performs one encryption or decryption action. If HTTP packets are received, the half mode SSL server encrypts them and converts them to HTTPS packets. If HTTPS packets are received, the SSL server decrypts them and converts them to HTTP packets.

Half mode SSL server configuration

In half mode, the FortiGate unit is acting like an SSL accelerator, offloading HTTPS decryption from the web server to the FortiGate unit. Since FortiGate units can accelerate SSL processing, the end result could be improved web site performance.

Usually the port of the encrypted traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. No matter what port is used for the HTTPS traffic, the decrypted HTTP traffic uses port 80.

Changing the ports on which to look for HTTP and HTTPS traffic to cache

By default FortiOS assumes HTTP traffic uses TCP port 80 and HTTPS traffic uses port 443. So web caching caches all HTTP traffic accepted by a policy on TCP port 80 and all HTTPS traffic on TCP port 443. If you want to cache HTTP or HTTPS traffic on other ports, you can enable security profiles for the security policy and configure

a proxy options profile to that looks for HTTP and HTTPS traffic on other TCP ports. To configure a proxy options profile go to **Network > Explicit Proxy**.

Setting the HTTP port to **Any** in a proxy options profile is not compatible with web caching. If you set the HTTP port to any, web caching only caches HTTP traffic on port 80.

Web caching and HA

You can configure web caching on a FortiGate HA cluster. The recommended best practice HA configuration for web caching is active-passive mode. When the cluster is operating, all web caching sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance web caching sessions.

In a cluster, only the primary unit stores the web cache database. The databases is not synchronized to the subordinate units. So, after a failover, the new primary unit must build its web cache.

Web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency, web caching uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, web caching requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When web caching is enabled you will see a reduction in available memory. The reduction increases when more web caching sessions are being processed. If you are thinking of enabling web caching on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by web caching. See `get test {wad | wccpd} <test_level>` on page 1 for more information.

Changing web cache settings

In most cases, the default settings for the WAN optimization web cache are acceptable. However, you may want to change them to improve performance or optimize the cache for your configuration. To change these settings, go to **WAN Opt. & Cache > Settings**.

From the FortiGate CLI, you can use the `config wanopt webcache` command to change these WAN optimization web cache settings.

For more information about many of these web cache settings, see [RFC 2616](#).

Always revalidate

Select to always revalidate requested cached objects with content on the server before serving them to the client.

Max cache object size

Set the maximum size of objects (files) that are cached. The default size is 512000 KB and the range is 1 to 4294967 KB. This setting determines the maximum object size to store in the web cache. Objects that are larger than this size are still delivered to the client but are not stored in the FortiGate web cache.

For most web traffic the default maximum cache object size is recommended. However, since web caching can also cache larger objects such as Windows updates, Mac OS updates, iOS updates or other updates delivered using HTTP you might want to increase the object size to make sure these updates are cached. Caching these updates can save a lot of Internet bandwidth and improve performance when major updates are released by these vendors.

Negative response duration

Set how long in minutes that the FortiGate unit caches error responses from web servers. If error responses are cached, then subsequent requests to the web cache from users will receive the error responses regardless of the actual object status.

The default is 0, meaning error responses are not cached. The content server might send a client error code (4xx HTTP response) or a server error code (5xx HTTP response) as a response to some requests. If the web cache is configured to cache these negative responses, it returns that response in subsequent requests for that page or image for the specified number of minutes.

Fresh factor

Set the fresh factor as a percentage. The default is 100, and the range is 1 to 100%. For cached objects that do not have an expiry time, the web cache periodically checks the server to see if the objects have expired. The higher the **Fresh Factor** the less often the checks occur.

For example, if you set the **Max TTL** value and **Default TTL** to 7200 minutes (5 days) and set the **Fresh Factor** to 20, the web cache check the cached objects 5 times before they expire, but if you set the **Fresh Factor** to 100, the web cache will check once.

Max TTL

The maximum amount of time (Time to Live) an object can stay in the web cache without the cache checking to see if it has expired on the server. The default is 7200 minutes (120 hours or 5 days) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Min TTL

The minimum amount of time an object can stay in the web cache before the web cache checks to see if it has expired on the server. The default is 5 minutes and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Default TTL

The default expiry time for objects that do not have an expiry time set by the web server. The default expiry time is 1440 minutes (24 hours) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Proxy FQDN

The fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP request length

The maximum length of an HTTP request that can be cached. Larger requests will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP message length

The maximum length of an HTTP message that can be cached. Larger messages will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Ignore

Select the following options to ignore some web caching features.

If-modified-since	By default, if the time specified by the if-modified-since (IMS) header in the client's conditional request is greater than the last modified time of the object in the cache, it is a strong indication that the copy in the cache is stale. If so, HTTP does a conditional GET to the Overlay Caching Scheme (OCS), based on the last modified time of the cached object. Enable ignoring if-modified-since to override this behavior.
HTTP 1.1 conditionals	HTTP 1.1 provides additional controls to the client over the behavior of caches toward stale objects. Depending on various cache-control headers, the FortiGate unit can be forced to consult the OCS before serving the object from the cache. For more information about the behavior of cache-control header values, see RFC 2616 . Enable ignoring HTTP 1.1 Conditionals to override this behavior.
Pragma-no-cache	Typically, if a client sends an HTTP GET request with a pragma no-cache (PNC) or cache-control no-cache header, a cache must consult the OCS before serving the content. This means that the FortiGate unit always re-fetches the entire object from the OCS, even if the cached copy of the object is fresh. Because of this behavior, PNC requests can degrade performance and increase server-side bandwidth utilization. However, if you enable ignoring Pragma-no-cache, then the PNC header from the client request is ignored. The FortiGate unit treats the request as if the PNC header is not present.
IE Reload	Some versions of Internet Explorer issue Accept / header instead of Pragma no-cache header when you select Refresh . When an Accept header has only the / value, the FortiGate unit treats it as a PNC header if it is a type-N object. Enable ignoring IE reload to cause the FortiGate unit to ignore the PNC interpretation of the Accept / header.

Cache expired objects

Applies only to type-1 objects. When this option is selected, expired type-1 objects are cached (if all other conditions make the object cacheable).

Revalidated pragma-no-cache

The pragma-no-cache (PNC) header in a client's request can affect how efficiently the FortiGate unit uses bandwidth. If you do not want to completely ignore PNC in client requests (which you can do by selecting to ignore Pragma-no-cache, above), you can nonetheless lower the impact on bandwidth usage by selecting **Revalidate Pragma-no-cache**.

When you select **Revalidate Pragma-no-cache**, a client's non-conditional PNC-GET request results in a conditional GET request sent to the OCS if the object is already in the cache. This gives the OCS a chance to return the 304 Not Modified response, which consumes less server-side bandwidth, because the OCS has not been forced to otherwise return full content.

By default, **Revalidate Pragma-no-cache** is disabled and is not affected by changes in the top-level profile.

Most download managers make byte-range requests with a PNC header. To serve such requests from the cache, you should also configure byte-range support when you configure the **Revalidate pragma-no-cache** option.

Web cache configuration

Forwarding URLs to forwarding servers and exempting web sites from web caching

You can go to **Network > Explicit Proxy** and use the URL match list to forward URL patterns to forwarding servers and create a list of URLs that are exempt from web caching.

Forwarding URLs and URL patterns to forwarding servers

As part of configuring the explicit web proxy you can configure proxy chaining by adding web proxy forwarding servers. See [Proxy chaining \(web proxy forwarding servers\)](#).

You can then use the URL match list to always forward explicit web proxy traffic destined for configured URLs or URL patterns to one of these forwarding servers. For example, you might want to forward all traffic for a specific country to a proxy server located in that country.

To forward traffic destined for a URL to a forwarding server that you have already added, go to **Network > Explicit Proxy** and select **Create New**. Add a name for the URL match entry and enter the URL or URL pattern. You can use wildcards such as * and ? and you can use a numeric IP address. Select **Forward to Server** and select a web proxy forwarding server from the list.

You can also exempt the URL or URL pattern from web caching.

Use the following command to forward all .ca traffic to a proxy server and all .com traffic to another proxy server.

```
config web-proxy url-match
  edit "com"
    set forward-server "server-commercial"
    set url-pattern "com"
  next
  edit "ca"
    set forward-server "server-canada"
    set url-pattern "ca"
  next
  edit "www.google.ca"
    set cache-exemption enable
    set url-pattern "www.google.ca"
  next
end
```

Exempting web sites from web caching

You may want to exempt some URLs from web caching for a number of reasons. For example, if your users access websites that are not compatible with FortiGate web caching you can add the URLs of these web sites to the web caching exempt list. You can add URLs and numeric IP addresses to the web cache exempt list.

You can also add URLs to the web cache exempt list by going to **Network > Explicit Proxy**, going to the **URL Match List**

URL Match List

☐

Exempt from Cache

☒

Enable this URL

☒

You can also add URLs and addresses to be exempt from caching using the CLI. Enter the following command to add `www.example.com` to the web cache exempt list:

```
config web-proxy url-match
  set cache-exemption enable
  set url-pattern www.example.com
end
```

Exempting specific files from caching

You can exempt files from being cached, so long as you specify its full URL. Enter the following command to add the URL, with the file extension (in this example, `.exe`), to the web cache exempt list:

```
config web-proxy url-match
  edit "exe"
    set url-pattern "iavs9x.u.avast.com/custom/iavs9x/20160613t1237z/avast_free_
      antivirus_setup_online.exe"
    set cache-exemption enable
  next
end
```

You cannot use wildcards to exempt file extensions in general from caching.

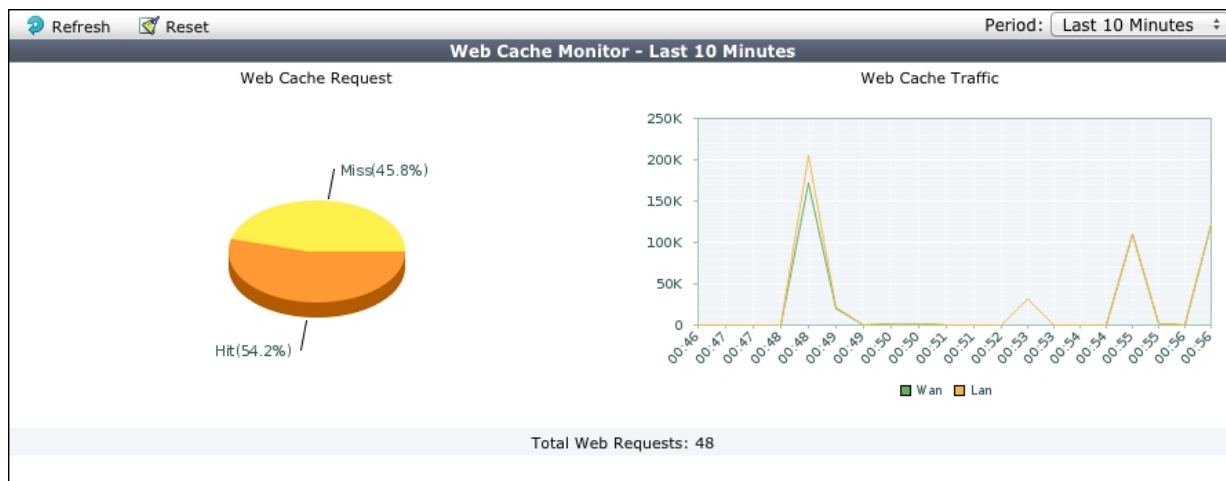

Monitoring web caching performance

The web cache monitor shows the percentage of web cache requests that retrieved content from the cache (hits) and the percentage that did not receive content from the cache (misses). A higher the number of hits usually indicates that the web cache is being more effective at reducing WAN traffic.

The web cache monitor also shows a graph of web traffic on the WAN and LAN. A lower WAN line on the graph indicates the web cache is reducing traffic on the WAN. The web cache monitor also displays the total number of web requests processed by the web cache.

To view the web cache monitor, go to **Monitor > Cache Monitor**.

Web cache monitor

Example web caching of HTTP and HTTPS Internet content for users on an internal network

This example describes how to configure web caching of HTTP and HTTPS for users on a private network connecting to the Internet.

Network topology and assumptions

This example includes a client network with subnet address 10.31.101.0 connecting to web servers on the Internet. All of the users on the private network access the Internet through a single general security policy on the FortiGate unit that accepts all sessions connecting to the Internet. Web caching for HTTP and HTTPS traffic is added to this security policy.

Since users on the private network have unrestricted access to the Internet and can be accessing many web servers the `webcache-https` is set to `any` and users may see error messages on their web browsers when accessing HTTPS content.

The GUI is less versatile than the CLI so the example instructions for the GUI give settings for one port for each protocol, while the CLI example shows how to use multiple ports.

The example also describes how to configure the security policy to cache HTTP traffic on port 80 and 8080 in the CLI, by adding a proxy options profile that looks for HTTP traffic on TCP ports 80 and 8080. The example also

describes how to configure the security policy to cache HTTPS traffic on port 443 and 8443 using the same proxy options profile.

Example web caching topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Add HTTP web caching to the security policy that all users on the private network use to connect to the Internet.
2. Add HTTPS web caching.
3. Add a protocol options profile to look for HTTP traffic on ports 80 and 8080 and HTTPS traffic on ports 443 and 8443 and add this protocol options profile to the security policy.

If you perform any additional actions between procedures, your configuration may have different results.

Configuration steps - web-based manager

Use the following steps to configure the example configuration from the FortiGate web-based manager.

To add HTTP web caching to a security policy

1. Go to **Policy & Objects > IPv4 Policy** and add a security policy that allows all users on the internal network to access the Internet.

Incoming Interface	Internal
Outgoing Interface	wan1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

2. Toggle **NAT** to enabled, and select **Use Outgoing Interface Address**.
3. Turn on **Web cache**.
4. Select **OK**.

To add HTTPS web caching

1. From the CLI enter the following command to add HTTPS web caching to the policy.

Assume the index number of the policy is 5.

```
config firewall policy
edit 5
set webcache-https any
end
```

To cache HTTP traffic on port 80 and HTTPS on 8443

1. Go to **Network > Explicit Proxy** and edit the Explicit Proxy options profile.
2. Under **Explicit Web Proxy**,
 - For the **HTTP port**, enter 80.
 - For **HTTPS port**, select **Specify** and enter 8443 in the field.
3. Click on **Apply**.

You need to use the CLI to add the protocol options profile unless you also add a security profile that uses proxy-based inspection.

Configuration steps - CLI

Use the following steps to configure the example configuration from the FortiGate CLI.

To add HTTP and HTTPS web caching to a security policy

1. Enter the following command to add a security policy that allows all users on the internal network to access the Internet and that includes web caching of HTTP and HTTPS traffic.

```
config firewall policy
edit 0
set srcintf internal
set srcaddr all
set dstintf wan1
set dstintf all
set schedule always
set service ANY
set action accept
set nat enable
set webcache enable
set webcache-https any
end
```

To cache HTTP traffic on port 80 and 8080 and HTTPS traffic on ports 443 and 8443

1. Enter the following command to edit the **default** proxy options profile to configure it to look for HTTP traffic on ports 80 and 8080:

```
config firewall profile-protocol-options
edit default
config http
set status enable
set ports 80 8080
```

```
end
```

2. Enter the following command to edit the **certificate-inspection** SSL SSH options profile to configure it to look for HTTPS traffic on ports 443 and 8443:

```
config firewall ssl-ssh-profile
edit certificate-inspection
config https
set status certificate-inspection
set ports 443 8443
end
```

3. Enter the following command to add the **default** proxy options profile and the **certificate-inspection** SSL SSH profile to the firewall policy.

```
config firewall policy
edit 5
set utm-status enable
set profile-protocol-options default
set ssl-ssh-profile certificate-inspection
end
```

Example reverse proxy web caching and SSL offloading for an Internet web server using a static one-to-one virtual IP

This section describes configuring SSL offloading for a reverse proxy web caching configuration using a static one-to-one firewall virtual IP (VIP). While the static one-to-one configuration described in this example is valid, its also common to change the destination port of the unencrypted HTTPS traffic to a commonly used HTTP port such as 8080 using a port forwarding virtual IP.

Network topology and assumptions

In this configuration, clients on the Internet use HTTP and HTTPS to browse to a web server that is behind a FortiGate unit. A policy added to the FortiGate unit forwards the HTTP traffic to the web server. The policy also offloads HTTPS decryption and encryption from the web server so the web server only sees HTTP traffic.

The FortiGate unit also caches HTTP and HTTPS pages from the web server so when users access cached pages the web server does not see the traffic. Replies to HTTPS sessions are encrypted by the FortiGate unit before returning to the clients.

In this configuration, the FortiGate unit is operating as a web cache in reverse proxy mode. Reverse proxy caches can be placed directly in front of a web server. Web caching on the FortiGate unit reduces the number of requests that the web server must handle, therefore leaving it free to process new requests that it has not serviced before.

Using a reverse proxy configuration:

- avoids the capital expense of additional web servers by increasing the capacity of existing servers
- serves more requests for static content from web servers
- serves more requests for dynamic content from web servers
- reduces operating expenses including the cost of bandwidth required to serve content
- accelerates the response time of web servers and of page download times to end users.

When planning a reverse proxy implementation, the web server's content should be written so that it is "cache aware" to take full advantage of the reverse proxy cache.

In reverse proxy mode, the FortiGate unit functions more like a web server for clients on the Internet. Replicated content is delivered from the proxy cache to the external client without exposing the web server or the private network residing safely behind the firewall.

In this example, the site URL translates to IP address 192.168.10.1, which is the port2 IP address of the FortiGate unit. The port2 interface is connected to the Internet.

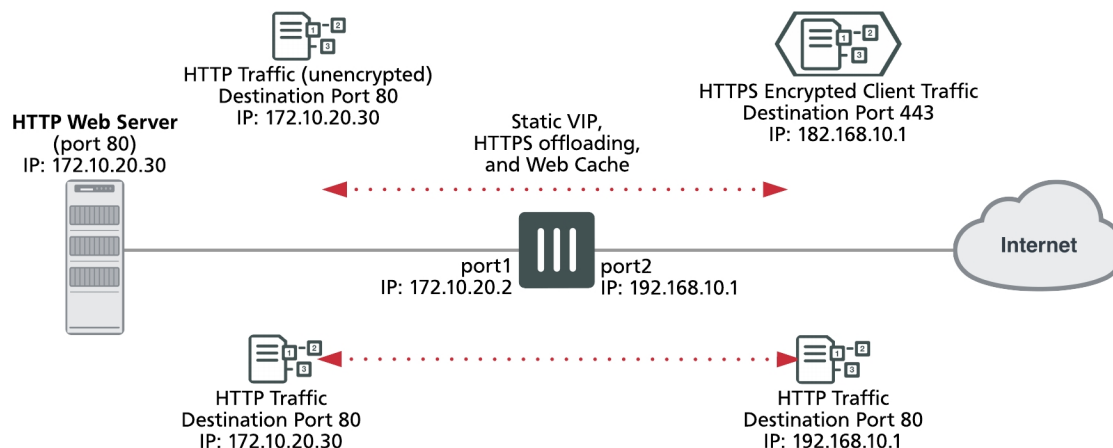

This example assumes that all HTTP traffic uses port 80 and all HTTPS traffic uses port 443.

The FortiGate unit includes the web server CA and an SSL server configuration for IP address 172.10.20.30 and port to 443. The name of the file containing the CA is Rev_Proxy_Cert_1.crt.

The destination address of incoming HTTP and HTTPS sessions is translated to the IP address of the web server using a static one-to-one virtual IP that performs destination address translation (DNAT) for the HTTP packets. The DNAT translates the destination address of the packets from 192.168.10.1 to 172.10.20.30 but does not change the destination port number.

When the SSL server on the FortiGate unit decrypts the HTTPS packets their destination port is changed to port 80.

Reverse proxy web caching and SSL offloading for an Internet web server using static one-to-one virtual IPs

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the FortiGate unit as a reverse proxy web cache server.
2. Configure the FortiGate unit for SSL offloading of HTTPS traffic.
3. Add an SSL server to offload SSL encryption and decryption for the web server.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuration steps - web-based manager

To configure the FortiGate unit as a reverse proxy web cache server

1. Go to **Policy & Objects > Virtual IPs** and select **Create New** to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

VIP Type	IPv4
Name	Reverse_proxy_VIP
Interface	port2
Type	Static NAT
Optional Filters	Do not select.
External IP Address/Range	192.168.10.1
Mapped IP Address/Range	172.10.20.30
Port Forwarding	Do not select.

2. Select **OK**.
3. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet.

Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	Reverse_proxy_VIP
Schedule	always
Service	HTTP HTTPS
Action	ACCEPT

4. Turn on **Web Cache**.
5. Select **OK**.
6. From the CLI enter the following command to add HTTPS web caching to the security policy

Assume the index number of the policy is 5.

```
config firewall policy
edit 5
set webcache-https ssl-server
end
```

To configure the FortiGate unit to offload SSL encryption and cache HTTPS content

1. Go to **System > Certificates** and select **Import** to import the web server's CA.

For **Type**, select **Local Certificate**. Select the **Browse** button to locate the file (example file name: Rev_Proxy_Cert_1.crt).

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

2. Select **OK** to import the certificate.
3. From the CLI, enter the following command to add the SSL server and to add the server's certificate to the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config firewall ssl-server
  edit rev_proxy_server
    set ip 172.10.20.30
    set port 443
    set ssl-mode half
    set ssl-cert Rev_Proxy_Cert_1
  end
```

Configuration steps - CLI

To configure the FortiGate unit as a reverse proxy web cache server

1. Enter the following command to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

```
config firewall vip
  edit Reverse_proxy_VIP
    set extintf port2
    set type static-nat
    set extip 192.168.10.1
    set mappedip 172.10.20.30
  end
```

2. Enter the following command to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet. Enable web caching and HTTPS web caching.

Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

```
config firewall policy
  edit 0
    set srcintf port2
    set srcaddr all
    set dstintf port1
    set dstaddr Reverse_proxy_VIP
    set schedule always
    set service HTTP HTTPS
    set action accept
    set webcache enable
    set webcache-https ssl-server
  end
```

To add an SSL server to offload SSL encryption and decryption for the web server

1. Place a copy of the web server's CA (file name `Rev_Proxy_Cert_1.crt`) in the root folder of a TFTP server.
2. Enter the following command to import the web server's CA from a TFTP server. The IP address of the TFTP server is 10.31.101.30:

```
execute vpn certificate local import tftp Rev_Proxy_Cert_1.crt 10.31.101.30
```

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

3. From the CLI, enter the following command to add the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config firewall ssl-server
edit rev_proxy_server
set ip 172.10.20.30
set port 443
set ssl-mode half
set ssl-cert Rev_Proxy_Cert_1
end
```

4. Configure other `ssl-server` settings that you may require for your configuration.

Using a FortiCache as a cache service

Some FortiGate devices don't have sufficient memory or disk space to run a cache service. This feature allows a FortiGate to connect to a FortiCache that has a higher cache capability than most FortiGates.

Syntax:

```
config wanopt remote-storage
set status {enable|disable}
set local-cache-id <name ID for connection>
set remote-cache-id <ID of the remote device>
set remote-cache-ip <IP address of the remote device>
end
```

Option	Description
status	Enable or disable whether the FortiGate uses a remote caching device as web-cache storage. If disabled, uses local disk(s) as web storage.
local-cache-id	ID that this device uses to connect to the remote caching device
remote-cache-id	ID of the remote caching device that this FortiGate connects to
remote-cache-ip	IP address of the remote caching device that this FortiGate connects to.

WCCP concepts

The Web Cache Communication Protocol (WCCP) can be used to provide web caching with load balancing and fault tolerance. In a WCCP configuration, a WCCP server receives HTTP requests from user's web browsers and redirects the requests to one or more WCCP clients. The clients either return cached content or request new content from the destination web servers before caching it and returning it to the server which in turn returns the content to the original requestor. If a WCCP configuration includes multiple WCCP clients, the WCCP server load balances traffic among the clients and can detect when a client fails and failover sessions to still operating clients. WCCP is described by the [Web Cache Communication Protocol Internet draft](#).

The sessions that are cached by WCCP depend on the configuration of the WCCP clients. If the client is a FortiGate unit, you can configure the port numbers and protocol number of the sessions to be cached. For example, to cache HTTPS traffic on port 443 the WCCP client port must be set to 443 and protocol must be set to 6. If the WCCP client should also cache HTTPS traffic on port 993 the client ports option should include both port 443 and 993.

On a FortiGate unit, WCCP sessions are accepted by a security policy before being cached. If the security policy that accepts sessions that do not match the port and protocol settings in the WCCP clients the traffic is dropped.

WCCP is configured per-VDOM. A single VDOM can operate as a WCCP server or client (not both at the same time). FortiGate units are compatible with third-party WCCP clients and servers. If a FortiGate unit is operating as an Internet firewall for a private network, you can configure it to cache and serve some or all of the web traffic on the private network using WCCP by adding one or more WCCP clients, configuring WCCP server settings on the FortiGate unit and adding WCCP security policies that accept HTTP session from the private network.

FortiGate units support WCCPv1 and WCCPv2. A FortiGate unit in NAT/Route or transparent mode can operate as a WCCP server. To operate as a WCCP client a FortiGate unit must be in NAT/Route mode. FortiGate units communicate between WCCP servers and clients over UDP port 2048. This communication can be encapsulated in a GRE tunnel or just use layer 2 forwarding.

A WCCP server can also be called a WCCP router. A WCCP client can also be called a WCCP cache engine.

WCCP Cisco to FortiGate client using L2-forwarding tunneling

FortiGate supports the option of using Mask mode, in addition to Hash mode, when operating as a WCCP client using L2 forwarding. As a result, you can configure a WCCP FortiGate client to connect to a Cisco Nexus, which doesn't accept the Hash mode assignment method, using the Mask mode assignment method.

WCCP configuration

WCCP configuration overview

To configure WCCP you must create a service group that includes WCCP servers and clients. WCCP servers intercept sessions to be cached (for example, sessions from users browsing the web from a private network). To intercept sessions to be cached the WCCP server must include a security policy that accepts sessions to be cached and WCCP must be enabled in this security policy.

The server must have an interface configured for WCCP communication with WCCP clients. That interface sends and receives encapsulated GRE traffic to and from WCCP clients. The server must also include a WCCP service group that includes a service ID and the addresses of the WCCP clients as well as other WCCP configuration options.

To use a FortiGate unit as a WCCP client, the FortiGate unit must be set to be a WCCP client (or cache engine). You must also configure an interface on the client for WCCP communication. The client sends and receives encapsulated GRE traffic to and from the WCCP server using this interface.

The client must also include a WCCP service group with a service ID that matches a service ID on the server. The client service group also includes the IP address of the servers in the service group and specifies the port numbers and protocol number of the sessions that will be cached on the client.

When the client receives sessions from the server on its WCCP interface, it either returns cached content over the WCCP interface or connects to the destination web servers using the appropriate interface depending on the client routing configuration. Content received from web servers is then cached by the client and returned to the WCCP server over the WCCP link. The server then returns the received content to the initial requesting user web browser.

Finally you may also need to configure routing on the server and client FortiGate units and additional security policies may have to be added to the server to accept sessions not cached by WCCP.

WCCP service groups, service numbers, service IDs and well known services

A FortiGate unit configured as a WCCP server or client can include multiple server or client configurations. Each of these configurations is called a WCCP service group. A service group consists of one or more WCCP servers (or routers) and one or more WCCP clients working together to cache a specific type of traffic. The service group configuration includes information about the type of traffic to be cached, the addresses of the WCCP clients and servers and other information about the service.

A service group is identified with a numeric WCCP service ID (or service number) in the range 0 to 255. All of the servers and clients in the same WCCP service group must have service group configurations with the same WCCP service ID.

The value of the service ID provides some information about the type of traffic to be cached by the service group. Service IDs in the range 0 to 50 are reserved for well known services. A well known service is any service that is defined by the WCCP standard as being well known. Since the service is well known, just the service ID is required to identify the traffic to be cached.

Even though the well known service ID range is 0 to 50, at this time only one well known service has been defined. Its service ID 0, which is used for caching HTTP (web) traffic.

So to configure WCCP to cache HTTP sessions you can add a service group to the WCCP router and WCCP clients with a service ID of 0. No other information about the type of traffic to cache needs to be added to the service group.

Since service IDs 1 to 50 are reserved for well know services and since these services are not defined yet, you should not add service groups with IDs in the range 1 to 50.

FortiOS does allow you to add service groups with IDs between 1 and 50. Since these service groups have not been assigned well known services, however, they will not cache any sessions. Service groups with IDs 51 to 255 allow you to set the port numbers and protocol number of the traffic to be cached. So you can use service groups with IDs 51 to 255 to cache different kinds of traffic based on port numbers and protocol number of the traffic. Service groups 1 to 50; however, do not allow you to set port numbers or protocol numbers so cannot be used to cache any traffic.

To cache traffic other than HTTP traffic you must add service groups with IDs in the range 51 to 255. These service group configurations must include the port numbers and protocol number of the traffic to be cached. It is the port and protocol number configuration in the service group that determines what traffic will be cached by WCCP.

Example WCCP server and client configuration for caching HTTP sessions (service ID = 0)

Enter the following command to add a WCCP service group to a WCCP server that caches HTTP sessions. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service

ID of this service group is 0.

```
config system wccp
  edit 0
    set router-id 10.31.101.100
    set server-list 10.31.101.0 255.255.255.0
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures the client to cache HTTP sessions. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group is 0.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 0
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
  end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named `w.<vdom_name>` is added to the FortiGate configuration (for example `w.root`). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

Example WCCP server and client configuration for caching HTTPS sessions

Enter the following command to add a service group to a WCCP server that caches HTTPS content on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 80.

```
config system settings
    set wccp-cache-engine enable
end

config system wccp
    edit 80
        set router-id 10.31.101.100
        set server-list 10.31.101.0 255.255.255.0
        set ports 443
        set protocol 6
    end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTPS sessions on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 80 to match the service ID added to the server.

```
config system settings
    set wccp-cache-engine enable
end

config system wccp
    edit 80
        set cache-id 10.31.101.1
        set router-list 10.31.101.100
        set ports 443
        set protocol 6
    end
```

Example WCCP server and client configuration for caching HTTP and HTTPS sessions

You could do this by configuring two WCCP service groups as described in the previous examples. Or you could use the following commands to configure one service group for both types of traffic. The example also caches HTTP sessions on port 8080.

Enter the following command to add a service group to a WCCP server that caches HTTP sessions on ports 80 and 8080 and HTTPS sessions on port 443. Both of these protocols use protocol number 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 90.

```
config system wccp
    edit 90
        set router-id 10.31.101.100
        set server-list 10.31.101.0 255.255.255.0
        set ports 443 80 8080
        set protocol 6
    end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTP sessions on port 80 and 8080 and HTTPS sessions on port 443. The IP

address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 90 to match the service ID added to the server.

```
config system settings
    set wccp-cache-engine enable
end
config system wccp
    edit 90
        set cache-id 10.31.101.1
        set router-list 10.31.101.100
        set ports 443 80 8080
        set protocol 6
    end
```

Other WCCP service group options

In addition to using WCCP service groups to define the types of traffic to be cached by WCCP the following options are available for servers and clients.

Server configuration options

The server configuration must include the `router-id`, which is the WCCP server IP address. This is the IP address of the interface that the server uses to communicate with WCCP clients.

The `group-address` is used for multicast WCCP configurations to specify the multicast addresses of the clients.

The `server-list` defines the IP addresses of the WCCP clients that the server can connect to. Often the server list can be the address of the subnet that contains the WCCP clients.

The `authentication` option enables or disables authentication for the WCCP service group. Authentication must be enabled on all servers and clients in a service group and members of the group must have the same password.

The `forward-method` option specifies the protocol used for communication between the server and clients. The default forwarding method is GRE encapsulation. If required by your network you can also select to use unencapsulated layer-2 packets instead of GRE or select any to allow both. The `return-method` allows you to specify the communication method from the client to the server. Both GRE and layer-2 are supported.

The `assignment-method` determines how the server load balances sessions to the clients if there are multiple clients. Load balancing can be done using hashing or masking.

Client configuration options

The client configuration includes the `cache-id` which is the IP address of the FortiGate interface of the client that communicates with WCCP server. The `router-list` option is the list of IP addresses of the WCCP servers in the WCCP service group.

The `ports` option lists the port numbers of the sessions to be cached by the client and the `protocol` sets the protocol number of the sessions to be cached. For TCP sessions the protocol is 6.

The `service-type` option can be auto, dynamic or standard. Usually you would not change this setting.

The client configuration also includes options to influence load balancing including the `primary-hash`, `priority`, `assignment-weight` and `assignment-bucket-format`.

Example caching HTTP sessions on port 80 using WCCP

In this example configuration (shown below), a FortiGate unit with host name WCCP_srv is operating as an Internet firewall for a private network is also configured as a WCCP server. The port1 interface of WCCP_srv is connected to the Internet and the port2 interface is connected to the internal network.

All HTTP traffic on port 80 that is received at the port2 interface of WCCP_srv is accepted by a port2 to port1 security policy with WCCP enabled. All other traffic received at the port2 interface is allowed to connect to the Internet by adding a general port2 to port1 security policy below the HTTP on port 80 security policy.

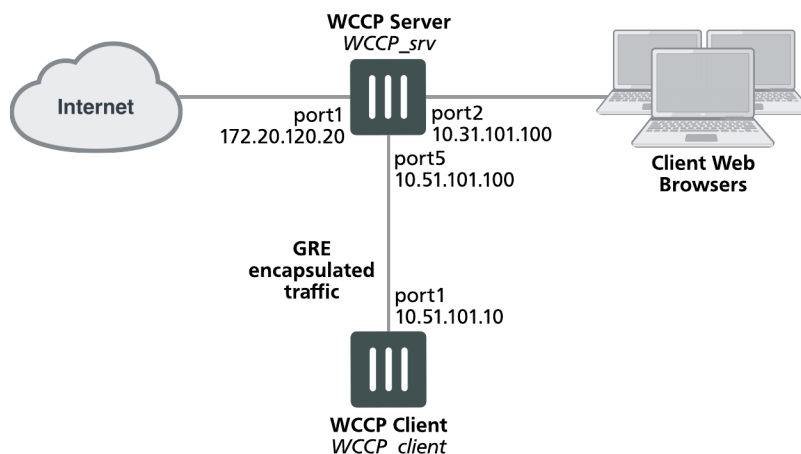

A WCCP service group is added to WCCP_srv with a service ID of 0 for caching HTTP traffic on port 80. The port5 interface of WCCP_srv is configured for WCCP communication.

A second FortiGate unit with host name WCCP_client is operating as a WCCP client. The port1 interface of WCCP_client is connected to port5 of WCCP_srv and is configured for WCCP communication.

WCCP_client is configured to cache HTTP traffic because it also has a WCCP service group with a service ID of 0.

WCCP_client connects to the Internet through WCCP_srv. To allow this, a port5 to port1 security policy is added to WCCP_srv.

FortiGate WCCP server and client configuration

Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and is configured for WCCP:

```

config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
  
```

```

        set action accept
        set schedule always
        set service HTTP
        set wccp enable
        set nat enable
    end

```

2. Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```

config firewall policy
    edit 0
        set srtintf port2
        set dstintf port1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
        set nat enable
    end

```

3. Move this policy below the WCCP policy in the port2 to port1 policy list.

4. Enable WCCP on the port5 interface.

```

config system interface
    edit port5
        set wccp enable
    end

```

5. Add a WCCP service group with service ID 0.

```

config system wccp
    edit 0
        set router-id 10.51.101.100
        set server-list 10.51.101.0 255.255.255.0
    end

```

6. Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```

config firewall address
    edit WCCP_client_addr
        set subnet 10.51.101.10
    end
config firewall policy
    edit 0
        set srtintf port5
        set dstintf port1
        set srcaddr WCCP_client_addr
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
        set nat enable
    end

```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
    set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named `w.<vdom_name>` is added to the FortiGate configuration (for example `w.root`). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2. Enable WCCP on the port1 interface.

```
config system interface
    edit port1
        set wccp enable
    end
```

3. Add a WCCP service group with service ID 0.

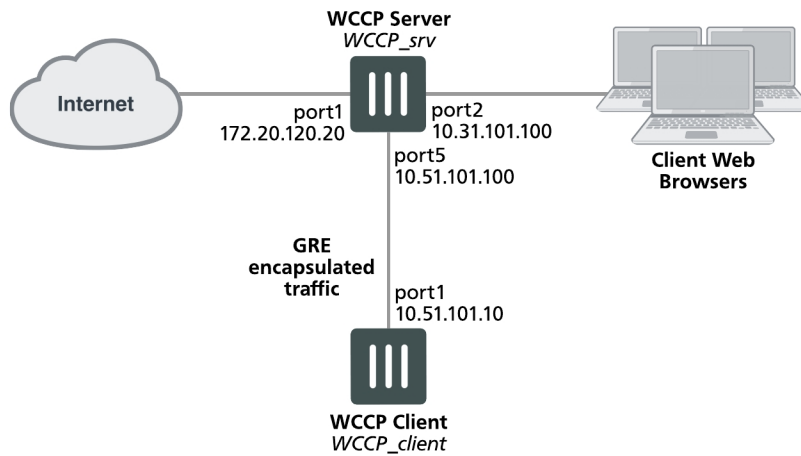

```
config system wccp
    edit 0
        set cache-id 10.51.101.10
        set router-list 10.51.101.100
    end
```

Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP

This example configuration is the same as that described in [Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP on page 842](#) except that WCCP now also cached HTTPS traffic on port 443. To cache HTTP and HTTPS traffic the WCCP service group must have a service ID in the range 51 to 255 and you must specify port 80 and 443 and protocol 6 in the service group configuration of the WCCP client.

Also the security policy on the WCCP_srv that accepts sessions from the internal network to be cached must accept HTTP and HTTPS sessions.

FortiGate WCCP server and client configuration

Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and HTTPS traffic on port 443 and is configured for WCCP:

```

config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service HTTP HTTPS
    set wccp enable
    set nat enable
  end

```

2. Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```

config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY

    set nat enable
  end

```

3. Move this policy below the WCCP policy in the port2 to port1 policy list.
4. Enable WCCP on the port5 interface.

```
config system interface
edit port5
set wccp enable
end
```

5. Add a WCCP service group with service ID 90 (can be any number between 51 and 255).

```
config system wccp
edit 90
set router-id 10.51.101.100
set server-list 10.51.101.0 255.255.255.0
end
```

6. Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
edit WCCP_client_addr
set subnet 10.51.101.10
end
config firewall policy
edit 0
set srtintf port5
set dstintf port1
set srcaddr WCCP_client_addr
set dstaddr all
set action accept
set schedule always
set service ANY
set nat enable
end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named `w.<vdom_name>` is added to the FortiGate configuration (for example `w.root`). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2. Enable WCCP on the port1 interface.

```
config system interface
edit port1
set wccp enable
```

```
end
```

3. Add a WCCP service group with service ID 90. This service group also specifies to cache sessions on ports 80 and 443 (for HTTP and HTTPS) and protocol number 6.

```
config system wccp
edit 90
set cache-id 10.51.101.10
set router-list 10.51.101.100
ports 80 443
set protocol 6
end
```

WCCP packet flow

The following packet flow sequence assumes you have configured a FortiGate unit to be a WCCP server and one or more FortiGate units to be WCCP clients.

1. A user's web browser sends a request for web content.
2. The FortiGate unit configured as a WCCP server includes a security policy that intercepts the request and forwards it to a WCCP client.

The security policy can apply UTM features to traffic accepted by the policy.

3. The WCCP client receives the WCCP session.
4. The client either returns requested content to the WCCP server if it is already cached, or connects to the destination web server, receives and caches the content and then returns it to the WCCP server.
5. The WCCP server returns the requested content to the user's web browser.
6. The WCCP router returns the request to the client web browser.

The client web browser is not aware that all this is taking place and does not have to be configured to use a web proxy.

Configuring the forward and return methods and adding authentication

The WCCP forwarding method determines how intercepted traffic is transmitted from the WCCP router to the WCCP cache engine. There are two different forwarding methods:

- GRE forwarding (the default) encapsulates the intercepted packet in an IP GRE header with a source IP address of the WCCP router and a destination IP address of the target WCCP cache engine. The result is a tunnel that allows the WCCP router to be multiple hops away from the WCCP cache server.
- L2 forwarding rewrites the destination MAC address of the intercepted packet to match the MAC address of the target WCCP cache engine. L2 forwarding requires that the WCCP router is Layer 2 adjacent to the WCCP client.

You can use the following command on a FortiGate unit configured as a WCCP router to change the forward and return methods to L2:

```
config system wccp
edit 1
set forward-method L2
set return-method L2
end
```

You can also set the forward and return methods to any in order to match the cache server configuration.

By default the WCCP communication between the router and cache servers is unencrypted. If you are concerned about attackers sniffing the information in the WCCP stream you can use the following command to enable hash-based authentication of the WCCP traffic. You must enable authentication on the router and the cache engines and all must have the same password.

```
config system wccp
  edit 1
    set authentication enable
    set password <password>
  end
```

WCCP messages

When the WCCP service is active on a web cache server it periodically sends a WCCP HERE I AM broadcast or unicast message to the FortiGate unit operating as a WCCP router. This message contains the following information:

- Web cache identity (the IP address of the web cache server).
- Service info (the service group to join).

If the information received in the previous message matches what is expected, the FortiGate unit replies with a WCCP I SEE YOU message that contains the following details:

- Router identity (the FortiGate unit's IP address).
- Sent to IP (the web cache IP addresses to which the packets are addressed)

When both ends receive these two messages the connection is established, the service group is formed and the designated web cache is elected.

Troubleshooting WCCP

Two types of debug commands are available for debugging or troubleshooting a WCCP connection between a FortiGate unit operating as a WCCP router and its WCCP cache engines.

Real time debugging

The following commands can capture live WCCP messages:

```
diag debug en
diag debug application wccpd <debug level>
```

Application debugging

The following commands display information about WCCP operations:

```
get test wccpd <integer>
diag test application wccpd <integer>
```

Where <integer> is a value between 1 and 6:

1. Display WCCP stats
2. Display WCCP config
3. Display WCCP cache servers
4. Display WCCP services
5. Display WCCP assignment
6. Display WCCP cache status

Enter the following command to view debugging output:

```
diag test application wccpd 3
```

Sample output from a successful WCCP connection:

```
service-0 in vdom-root: num=1, usable=1
cache server ID:
len=44, addr=172.16.78.8, weight=4135, status=0
rcv_id=6547, usable=1, fm=1, nq=0, dev=3(k3),
to=192.168.11.55
ch_no=0, num_router=1:
192.168.11.55
```

Sample output from the same command from an unsuccessful WCCP connection (because of a service group password mismatch):

```
service-0 in vdom-root: num=0, usable=0
diag debug application wccpd -1
Sample output:
wccp_on_recv()-98: vdom-root recv: num=160, dev=3(3),
172.16.78.8->192.168.11.55
wccp2_receive_pkt()-1124: len=160, type=10, ver=0200,
length=152
wccp2_receive_pkt()-1150: found component:t=0, len=20
wccp2_receive_pkt()-1150: found component:t=1, len=24
wccp2_receive_pkt()-1150: found component:t=3, len=44
wccp2_receive_pkt()-1150: found component:t=5, len=20
wccp2_receive_pkt()-1150: found component:t=8, len=24
wccp2_check_security_info()-326: MD5 check failed
```

Web proxy concepts

These are concepts that apply to both Transparent and Explicit Proxy.

Proxy policy

Information on Proxy policy options can be found at [Proxy option components on page 550](#)

Configuration information can be found at [Web proxy configuration on page 855](#)

Proxy authentication

Beginning in FortiOS 5.6, authentication is separated from authorization for user based policy. You can add authentication to proxy policies to control access to the policy and to identify users and apply different UTM features to different users. The described authentication methodology works with **Explicit Web Proxy** and **Transparent Proxy**.

Authentication of web proxy sessions uses HTTP basic and digest authentication as described in [RFC 2617 \(HTTP Authentication: Basic and Digest Access Authentication\)](#) and prompts the user for credentials from the browser allowing individual users to be identified by their web browser instead of IP address. HTTP authentication allows the FortiGate unit to distinguish between multiple users accessing services from a shared IP address.

The methodology of adding authentication has changed from FortiOS version 5.4 and previous version. Split-policy has been obsoleted and instead of identity-based-policy, authentication is managed by `authentication scheme`, `setting` and `rule` settings. These authentication settings are no longer configured with the individual policies. Authentication is set up in the contexts of:

```
config authentication scheme
config authentication setting
config authentication rule
```

The Authentication rule table defines how to identify user-ID. It uses the match factors:

- Protocol
- Source Address

For one address and protocol, there is only one authentication rule. It is possible to configure multiple authentication methods for on one address. The client browser will chose one authentication method from the authentication methods list, but you can not control which authentication method will be chosen by the browser.

Matching

If a rule is matched, the authentication methods defined in the rule will be used to authenticate a user. The procedure works as the following:

1. If it is IP-based, look up active user list to see a user existed from the source IP. If found, return the user ID.
2. If no method is set, an anonymous user is created to associate to the source-IP. Return the anonymous user. It is another way to bypass user authentication for some source IPs.
3. Use authentication methods to authenticate the user.
 - If no active method is defined, a failure will result to return an anonymous user.
 - Otherwise, a valid or guest user has to be identified to move on.

- Return the identified user ID.

Once a user is returned, the policy match resumes until a policy is matched or default policy will be used.

Processing policies for authentication

Authentication rules are checked once a User-ID is needed in order to resolve a match to a policy

Use the following scenario as an example of the process.

There are 3 policies:

- `policy1` does not have an associated user group
- `policy2` has an associated user group
- `policy3` does not have an associated user group

Step 1

If the traffic, based on protocol and source address matches `policy 1`, no user authentication is needed. The traffic is processed by `policy1`.

Step 2

If the traffic does not match `policy 1`, and any factor of `policy 2` is not matched, continue to next policy.

If all the factors except the user-group of `policy 2` are matched the authentication rule table is checked to get user-ID in the process in based on the procedure described earlier in Matching.

Step 3

When a user-ID is returned, whether it is a valid user or anonymous user, it is checked to see if the user is authorized by the user group associated with `policy2`. If yes, it is a match of `policy2`, and the traffic is processed by `policy2`. If not move on the next policy.

Step 4

For the purposes of the scenario, it will be assumed that the traffic either matches `policy3` or that `policy3` is the final policy that denies everything.

CLI syntax

Removals:

- "split-policy" from firewall explicit-proxy-policy.

The previous method to set up a split policy was:

```
config firewall explicit-proxy-policy
edit 1
    set proxy web
    set identity-based enable
    set groups <User group>
    config identity-based-policy
    edit 1
        set schedule "always"
        set utm-status enable
        set users "guest"
```

```

        set profile-protocol-options "default"
      next
    end
  next
end

```

- "auth relative" from firewall explicit-proxy-policy

The following attributes have been removed from firewall explicit-proxy-policy:

- identity-based
- ip-based
- active-auth-method
- sso-auth-method
- require-tfa

Moves:

users and groups from

```

firewall explicit-proxy-policy identity-based-policy
to

config firewall proxy-policy
  edit 1
    set groups <Group name>
    set users <User name>
  end

```

Additions:

authentication scheme

```

config authentication scheme
  edit <name>
    set method [ntlm|basic|digest|form|negotiate|fsso|rsso|none]
  end

```

- `ntlm` - NTLM authentication.
- `basic` - Basic HTTP authentication.
- `digest` - Digest HTTP authentication.
- `form` - Form-based HTTP authentication.
- `negotiate` - Negotiate authentication.
- `fsso` - FSSO authentication.
- `rsso` - RADIUS Single Sign-On authentication.
- `none` - No authentication.

authentication setting

```

config authentication setting
  set active-auth-scheme <string>
  set sso-auth-scheme <string>
  set captive-portal <string>
  set captive-portal-port <integer value from 1 to 65535>

```

- `active-auth-scheme` - Active authentication method.
- `sso-auth-scheme` - SSO authentication method.
- `captive-portal` - Captive portal host name.
- `captive-portal-port` - Captive portal port number.

authentication rule

```
config authentication rule
edit <name of rule>
    set status [enable|disable]
    set protocol [http|ftp|socks]
    set srcaddr <name of address object>
    set srcaddr6 <name of address object>
    set ip-based [enable|disable]
    set active-auth-method <string>
    set sso-auth-method <string>
    set web-auth-cookie [enable|disable]
    set transaction-based [enable|disable]
    set comments
```

- `status` - Enable/disable auth rule status.
- `protocol` - set protocols to be matched
- `srcaddr` / `srcaddr6` - Source address name. [`srcaddr` or `srcaddr6`(web proxy only) must be set].
- `ip-based` - Enable/disable IP-based authentication.
- `active-auth-method` - Active authentication method.
- `sso-auth-method` - SSO authentication method (require `ip-based` enabled)
- `web-auth-cookie` - Enable/disable Web authentication cookie.
- `transaction-based` - Enable/disable transaction based authentication.
- `comments` - Comment.

Configuring authentication in transparent proxy

You can enable transparent web-proxy feature to support authentication. Follow these steps

1. Configure a firewall policy
2. Enable a UTM profile in the firewall policy. Whenever there is a UTM item enabled, the feature enables the `profile-protocol-options`.
3. Go to the **Proxy Options** profile.
 - In the GUI this is **Security Profiles > Proxy Options**.
 - In the CLI it is `config firewall profile-protocol-options`.

Edit the profile used by the policy.

4. Enable HTTP in the profile.
In the GUI toggle on **HTTP** under **Protocol Port Mapping**

In the CLI, the command sequence is:

```
config firewall profile-protocol-options
edit <profile id>
    config http
        set status enable
    end
```

Fill out any other appropriate values.

5. Configure the proxy-policy, and set the value transparent-web for proxy option, others configuration are same as the explicit-web proxy

In the GUI, go to **Policy & Objects > Proxy Policy**. In the **Proxy Type** field choose **Transparent Web**.

In the CLI, the command sequence is:

```
config firewall proxy-policy
edit <profile id>
set proxy transparent-web
end
```

Fill out any other appropriate values.

6. Setup the authentication rule and scheme

With this configuration, if a HTTP request passes through FortiGate without explicit web proxy being applied, the traffic will be redirected to WAD daemon after it matches the proxy with HTTP-policy enabled, then WAD will do the proxy-policy matching, and all of the proxy authentication method can be used for the request.

Proxy addresses

Information on Proxy addresses can be found at [Proxy addresses on page 723](#)

Proxy address group

In the same way that IPv4 and IPv6 addresses can only be grouped together, Proxy addresses can only be grouped with other Proxy addresses. Unlike the other address groups, the Proxy address groups are further divided into source address groups and destination address groups. To see the configuration steps go to [Proxy address groups on page 725](#)

Web proxy firewall services and service groups

Configure web proxy services by selecting **Explicit Proxy** when configuring a service. Web proxy services can be selected in a explicit web proxy policy when adding one from the CLI. If you add a policy from the web-based manager the service is set to the **webproxy** service. The webproxy service should be used in most cases, it matches with any traffic with any port number. However, if you have special requirements, such as using a custom protocol type or a reduced port range or need to add an IP/FQDN to an proxy service you can create custom explicit web proxy services.

Web proxy services are similar to standard firewall services. You can configure web proxy services to define one or more protocols and port numbers that are associated with each web proxy service. Web proxy services can also be grouped into web proxy service groups.

One way in which web proxy services differ from firewall services is the protocol type you can select. The following protocol types are available:

- ALL
- CONNECT
- FTP
- HTTP

- SOCKS-TCP
- SOCKS-UDP

To add a web proxy service go to **Policy & Objects > Services** and select **Create New**. Set **Service Type** to **Explicit Proxy** and configure the service as required.

To add a web proxy service from the CLI enter:

```
config firewall service custom
edit my-socks-service
set explicit-proxy enable
set category Web Proxy
set protocol SOCKS-TCP
set tcp-portrange 3450-3490
end
```

To add a web proxy service group go to **Policy & Objects > Services** and select **Create New > Service Group**. Set **Type** to **Explicit Proxy** and add web proxy services to the group as required.

To add a web proxy service group from the CLI enter:

```
config firewall service group
edit web-group
set explicit-proxy enable
set member webproxy my-socks-service
end
```

Learn client IP

If there is another NATing device between the FortiGate and the Client (browser), this feature can be used to identify the real client in spite of the address translation. Knowing the actual client is imperative in cases where authorization is taking place.

The settings for the feature are in the CLI in the context of

```
config web-proxy global
```

Once here, enable the feature with the command:

```
set learn-client-ip enable
```

Once the feature is enabled, the other settings become available.

```
learn-client-ip-from-header
```

This command has the following options:

true-client-ip	Support HTTP header True-Client-IP.
x-real-ip	Support HTTP header X-Real-IP.
x-forwarded-for	Support HTTP header X-Forwarded-For.

```
learn-client-ip-srcaddr/learn-client-ip-srcaddr6
```

The options for this setting are selected from the list of IPv4 address or IPv6 address objects.

Example

Below is a config example where the real client ip address will be used to match policy or fsso authentication after the learn-client-ip feature enabled.

The value of `learn-client-ip-from-header` option can be set to `true-client-ip`, `x-real-ip` or `x-forwarded-for`, but in this case it has been set to `x-forward-for`.

```
config web-proxy global
    set proxy-fqdn "default.fqdn"
    set webproxy-profile "default"
    set learn-client-ip enable
    set learn-client-ip-from-header x-forwarded-for
    set learn-client-ip-srcaddr "all"
end

config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "mgmt1"
        set srcaddr "all"
        set dstaddr "all"
        set service "w"
        set action accept
        set schedule "always"
        set groups "fssol"
        set utm-status enable
        set av-profile "default"
        set dlp-sensor "default"
        set profile-protocol-options "default"
        set ssl-ssh-profile "deep-inspection"
    end

config authentication rule
    edit "rule1"
        set srcaddr "all"
        set sso-auth-method "scheme1"
    end

config authentication scheme
    edit "scheme1"
        set method fsso
    end
```

Web proxy configuration

General web proxy configuration steps

You can use the following general steps to configure the explicit web proxy.

To enable the explicit web proxy - web-based manager:

1. Go to **Network > Explicit Proxy** and enable **Explicit Web Proxy**. From here you can optionally change the HTTP port that the proxy listens on (the default is 8080) and optionally specify different ports for HTTPS, FTP, PAC, and other options.
2. Optionally enable **IPv6 Explicit Proxy** to turn on the explicit web proxy for IPv6 traffic.

If you enable both the IPv4 and the IPv6 explicit web proxy you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

3. Select **Apply**.
4. Go to **Network > Interfaces** and select one or more interfaces for which to enable the explicit web proxy. Edit the interface. Under the **Miscellaneous** heading select **Enable Explicit Web Proxy**.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

5. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address that matches the source address of packets to be accepted by the explicit proxy.

Category	Address
Name	Internal_subnet
Type	IP Range
Subnet / IP Range	10.31.101.1 - 10.31.101.255
Interface	any*

*The **Interface** must be set to **Any**.

You can also set the **Type** to **URL Pattern (Explicit Proxy)** to add a destination URL that is only used by the explicit proxy. For example, to create an explicit policy that only allows access to Fortinet.com:

Category	Address
Name	Fortinet-web-sites
Type	URL Pattern (Explicit Proxy)
URL Pattern	fortinet.com
Interface	any

6. Go to **Policy & Objects > Proxy Policy** and select **Create New**. Configure the policy as required to accept the traffic that you want to be allowed to use the explicit web proxy.
7. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
8. The **Source** of the policy must match the client's source IP addresses. The interface of this firewall address must be set to **any**.
9. The **Destination** field should match the addresses of web sites that clients are connecting to. Usually the destination address would be **all** if proxying Internet web browsing. You could also specify a URL firewall address to limit the policy to allowing access to this URL.
10. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
11. If **Default Firewall Policy Action** is set to **Deny** (under **Network > Explicit Proxy**), traffic sent to the explicit web proxy that is not accepted by a web-proxy policy is dropped. If **Default Firewall Policy Action** is set to **Allow** then all web-proxy sessions that don't match with a security policy are allowed.

For example, the following security policy allows users on an internal network to access fortinet.com websites through the wan1 interface of a FortiGate unit.

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	Fortinet-web-sites
Schedule	always
Action	ACCEPT

The explicit web-proxy accepts VIP addresses for destination addresses. If an external IP matches a VIP policy, the IP is changed to the mapped-IP of the VIP.

12. Set the **Disclaimer Options**

You can configure a disclaimer for each Authentication Rule by enabling one of the options here. The

choices are:

Disable	No disclaimer (default setting)
By Domain	The disclaimer will be displayed on different domains. The explicit web proxy will check the referring header to mitigate the javascript/css/images/video/etc page.
By Policy	The disclaimer will be displayed if the HTTP request matches a different explicit firewall policy.
By User	The disclaimer will be displayed when a new user logs on.

If you chose a disclaimer option other than **Disable**, you will have the option to enable **Customize Messages**. If enabled, select the **Edit Disclaimer Message** button to customize the message to your needs. This can be done as text or as HTML. The default HTML version is there if you just want to make minor changes.

13. Enable **Security Profiles** as required. Once the profile type is toggled to enabled, you can use the drop down menu to select a specific profile. The available profile types are:

- **AntiVirus**
- **WebFilter**
- **Application Control**
- **IPS**
- **DLP Sensor**
- **ICAP**
- **Web Application Firewall**

Just like with a regular policy, as soon as any of the **Security Profiles** is enabled, the following fields, with their own drop down menus for specific profiles will appear:

- **Proxy Options**
- **SSL/SSH Inspection**

14. Select **OK**.

To enable the explicit web proxy - CLI:

1. Enter the following command to turn on the IPv4 and IPv6 explicit web proxy for HTTP and HTTPS traffic.

```
config web-proxy explicit
  set status enable
  set ipv6-status enable
end
```

You can also enter the following command to enable the web proxy for FTP sessions in a web browser.

```
config web-proxy explicit
  set ftp-over-http enable
end
```

The default explicit web proxy configuration has `sec-default-action` set to `deny` and requires

you to add a security policy to allow access to the explicit web proxy.

2. Enter the following command to enable the explicit web proxy for the internal interface.

```
config system interface
edit internal
set explicit-web-proxy enable
end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit web proxy.

```
config firewall address
edit Internal_subnet
set type iprange
set start-ip 10.31.101.1
set end-ip 10.31.101.255
end
```

The source address for a web-proxy security policy cannot be assigned to a FortiGate interface.

4. Optionally use the following command to add a destination URL that is only used by the explicit proxy. For example, to create an explicit policy that only allows access to Fortinet.com:

```
config firewall address
edit Fortinet-web-sites
set type url
set url fortinet.com
end
```

5. Use the following command to add an explicit web proxy policy that allows all users on the internal subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
edit 0
set proxy explicit-web
set dstintf wan1
set scraddr Internal_subnet
set dstaddr all
set action accept
set service webproxy
set schedule always
end
```

6. Use the following command to add an explicit web proxy policy that allows authenticated users on the internal subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
edit 0
set proxy explicit-web
set dstintf wan1
set scraddr Internal_subnet
set dstaddr Fortinet-web-sites
set action accept
set service webproxy
set schedule always
set groups <User group>
end
end
```

7. Use the following command to change global web proxy settings, for example to set the maximum request length for the explicit web proxy to 10:

```
config web-proxy global
  set max-request-length 10
end
```

8. Determine whether or not to use Botnet feature.

The option `scan-botnet-connections` uses the following syntax:

```
config firewall proxy-policy
  edit <policy id>
    set scan-botnet-connections [disable|block|monitor]
  end
```

Where:

- `disable` means do not scan connections to botnet servers
- `block` means block connection to botnet servers
- `monitor` means log connections to botnet servers

Logging options in web proxy profiles

There is an option on what action to take regarding the authenticated user's name in the header information for reading by upstream proxies and systems. This option can be used when a FortiGate is operating as an explicit proxy and authenticating users. The header is the `x-authenticated-user` and is used by the upstream proxy to ensure correct policy enforcement and to log the user's activity.

The `log-header-change` option enables the logging of any header changes in the web-proxy profile, including changes to authenticated users or groups.

Syntax

```
config web-proxy profile
  edit <profile ID#>
    set header-x-authenticated-user {pass|add|remove}
    set header-x-authenticated-groups {pass|add|remove}
    set log-header-change {enable|disable}
  end
```

Option	Description
header-x-authenticated-user	Action to take on the HTTP <code>x-authenticated-user</code> header in forwarded requests: <ul style="list-style-type: none">• <code>pass</code> - Forward the same HTTP header• <code>add</code> - Add the HTTP header• <code>remove</code> - Remove the HTTP header

Option	Description
header-x-authenticated-groups	<p>Action to take on the HTTP <code>x-authenticated-groups</code> header in forwarded requests:</p> <ul style="list-style-type: none"> • <code>pass</code> - Forward the same HTTP header • <code>add</code> - Add the HTTP header • <code>remove</code> - Remove the HTTP header
log-header-change	<code>enable</code> or <code>disable</code> the logging of HTTP header changes

Policy matching based on referrer headers and query strings

Web proxy policies support creating web proxy addresses to match referrer headers and query strings.

Matching referrer headers

For example, to create a web proxy address to match the referrer header to block access to the following YouTube URL `http://youtube.com/user/test321`. The http request will have the following format:

```
GET /user/test321 HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*
```

Create the following web proxy addresses to match this page:

```
config firewall proxy-address
edit youtube
set type host-regex
set host-regex ".*youtube.com"
next
edit test321
set host "youtube"
set path "/user/test321"
set referrer enable
end
```

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the referrer header:

```
config firewall proxy-policy
edit 1
set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "all"
set service "webproxy-connect"
set action accept
set schedule "always"
set utm-status enable
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
edit 2
```

```

set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "test321"
set service "webproxy"
set action accept
set schedule "always"
set utm-status enable
set av-profile "default"
set profile-protocol-options "test"
set ssl-ssh-profile "test"
end

```

Matching query strings

To match the video with URL `youtube.com/watch?v=XXXXXXXXXX`, (where `XXXXXXXXXX` is an example YouTube query string) you need to match an HTTP request with the following format:

```

GET /user/watch?v=GLCHldlwQsg HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*

```

Create the following web proxy addresses to match this video or query string:

```

config firewall proxy-address
edit "youtube"
set uuid 4ad63880-971e-51e7-7b2e-c69423ac6314
set type host-regex
set host-regex ".*youtube.com"
next
edit "query-string"
set uuid 7687a8c0-9727-51e7-5063-05edda03abbf
set host "youtube"
set path "/watch"
set query "v=XXXXXXXXXX"
end

```

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the query string

```

config firewall proxy-policy
edit 1
set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "all"
set service "webproxy-connect"
set action accept
set schedule "always"
set utm-status enable
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
edit 2
set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
set proxy explicit-web
set dstintf "wan2"

```

```
set srcaddr "all"
set dstaddr "query-string"
set service "webproxy"
set action accept
set schedule "always"
set utm-status enable
set av-profile "default"
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
end
```

Multiple web proxy PAC files in one VDOM

Proxy auto-config (PAC) files automatically choose the appropriate proxy server for browsers and other user agents. Not every user in an organization has the same proxy server requirements. Supporting multiple PAC files provides granular control. To manage multiple PAC files, you use PAC policies.

This capability is available only when the FortiGate is in **Proxy-based** inspection mode.

If there is no matching PAC policy (by name), in the PAC policies, the global PAC file is used by default.

To enable Proxy mode:

GUI

1. Go to **System > Settings**.
2. In **System Operation Settings**, set the **Inspection Mode** to **Proxy**.

CLI

```
config system settings
set inspection-mode proxy
end
```

To configure a PAC policy

```
config web-proxy explicit
set status enable
set pack-file-server-status enable
config pac-policy
edit <policy ID#>
set srcaddr <name of IPv4 address object>
set srcaddr6 <name of IPv6 address object>
set dstaddr <name of address object>
set pac-file-name <string>
set pac-file-data "<PAC-file>"
end
```

Option	Description
srcaddr or srcaddr6	This address must conform to the following criteria: <ul style="list-style-type: none">• a range, mask or wildcard mask type of address or address group• source type proxy-address or group It can be either IPv4 or IPv6.
dstaddr	This address must conform to the following criteria: <ul style="list-style-type: none">• a range, mask or wildcard type of address or address group• it must be resolved as the FortiGate address
pac-file-name	Name of the PAC file.
pac-file-data	Enter the contents of the PAC file enclosed in quotes. It is permissible to use the Return key when entering the contents. Place the closing quote at the end of the last line. If quotes are used within the content of the file, use the escape character \ before the quote. Example: \"

The `pac-file-server-status` setting must be set to `enable` in order for the `config pac-policy` command to work.

Explicit proxy concepts

The following is information that is specific to Explicit Proxy concepts. Any information that is common to Web Proxy in general is covered in the more inclusive section of [Web proxy concepts on page 848](#)

The FortiGate explicit web proxy

You can use the FortiGate explicit web proxy to enable explicit proxying of IPv4 and IPv6 HTTP, and HTTPS traffic on one or more FortiGate interfaces. The explicit web proxy also supports proxying FTP sessions from a web browser and proxy auto-config (PAC) to provide automatic proxy configurations for explicit web proxy users. From the CLI you can also configure the explicit web proxy to support SOCKS sessions from a web browser.

The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

If explicit web proxy options are not visible on the web-based manager, go to **System > Feature Visibility** and turn on **Explicit Proxy**.

In most cases you would configure the explicit web proxy for users on a network by enabling the explicit web proxy on the FortiGate interface connected to that network. Users on the network would configure their web browsers to use a proxy server for HTTP and HTTPS, FTP, or SOCKS and set the proxy server IP address to the IP address of the FortiGate interface connected to their network. Users could also enter the PAC URL into their web browser PAC configuration to automate their web proxy configuration using a PAC file stored on the FortiGate unit.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in transparent mode, users would configure their browsers to use a proxy server with the FortiGate management IP address.

If the FortiGate unit is operating with multiple VDOMs the explicit web proxy is configured for each VDOM.

The web proxy receives web browser sessions to be proxied at FortiGate interfaces with the explicit web proxy enabled. The web proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit web proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in transparent mode the explicit web proxy changes the source addresses to the management IP address. You can configure the explicit web proxy to keep the original client IP address. See [The FortiGate explicit web proxy on page 864](#).

For more information about explicit web proxy sessions, see [The FortiGate explicit web proxy on page 864](#).

Example explicit web proxy topology

To allow all explicit web proxy traffic to pass through the FortiGate unit you can set the explicit web proxy default firewall policy action to accept. However, in most cases you would want to use security policies to control explicit web proxy traffic and apply security features such as access control/authentication, virus scanning, web filtering, application control, and traffic logging. You can do this by keeping the default explicit web proxy security policy action to deny and then adding web-proxy security policies.

You can also change the explicit web proxy default security policy action to accept and add explicit web proxy security policies. If you do this, sessions that match web-proxy security policies are processed according to the security policy settings. Connections to the explicit web proxy that do not match a web-proxy security policy are allowed with no restrictions or additional security processing. This configuration is not recommended and is not a best practice.

The explicit web-proxy can accept VIP addresses for destination address. If an external IP matches a VIP policy, the IP is changed to the mapped-IP of the VIP.

Web-proxy policies can selectively accept or deny traffic, apply authentication, enable traffic logging, and use security profiles to apply virus scanning, web filtering, IPS, application control, DLP, and SSL/SSH inspection to explicit web proxy traffic.

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit web proxy traffic. Web Proxy policies can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to **Any**. (On the web-based manager you must set the interface to **Any**. In the CLI you must `unset the associated-interface`.)

Authentication of explicit web proxy sessions uses HTTP authentication and can be based on the user's source IP address or on cookies from the user's web browser. For more information, see [The FortiGate explicit web proxy on page 864](#).

To use the explicit web proxy, users must add the IP address of a FortiGate interface on which the explicit web proxy is enabled and the explicit web proxy port number (default 8080) to the proxy configuration settings of their web browsers.

On FortiGate units that support it, you can also enable web caching for explicit web proxy sessions.

For the time being, traffic shaping is not supported per policy for explicit proxy. For explicit proxy traffic, traffic shaping can be carried out per interface.

Other explicit web proxy options

You can change the following explicit web proxy options as required by your configuration.

HTTP port, HTTPS port, FTP port, PAC port

The TCP port that web browsers use to connect to the explicit proxy for HTTP, HTTPS, FTP and PAC services. The default port is 8080 for all services. By default HTTPS, FTP, and PAC use the same port as HTTP. You can change any of these ports as required. Users configuring their web browsers to use the explicit web proxy should add the same port numbers to their browser configurations.

Multi-port support for Explicit Proxy

Support exists for the use of multiple ports and port range in the explicit FTP or Web proxies. These changes have been added in both CLI and GUI.

CLI:

```
set http-incoming-port <port_low>[-<port_high>]
```

Where:

- `port_low` - the low value of the port
- `port_high` - the high value of the port

The `port_high` value can be omitted if `port_low` and `port_high` are the same.

Proxy FQDN

Enter the fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server.

Max HTTP request length

Enter the maximum length of an HTTP request in Kbytes. Larger requests will be rejected.

Max HTTP message length

Enter the maximum length of an HTTP message in Kbytes. Larger messages will be rejected.

Multiple incoming ports and port ranges

Web proxy can be configured to listen on multiple ports on the same IP as well as listen for HTTP and HTTPS on those same (or different) ports. This is done in the CLI.

Define the IP ranges using a hyphen (-). As shown below, `port_high` is not necessary to specify if `port_low` is equal to `port_high`.

CLI syntax

```
config web-proxy explicit
  set http-incoming-port <port_low> [-<port_high>]
end
```

Internet services

FortiOS can use the Internet Service Database (introduced in 5.4.1) as a web-proxy policy matching factor. This can only be done in the CLI.

CLI syntax:

```
config firewall proxy-policy
edit 0
set internet-service <application-id>
set internet-service-custom <application-name>
```

IP pools

IP Pools can be used with web proxy. When using this option of setting the IP pool name, the outgoing IP will be selected.

CLI syntax

```
config firewall proxy-policy
edit <example>
set poolname <name>
end
```

Proxy chaining (web proxy forwarding servers)

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with an web proxy solution that you already have in place.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support authenticating with the remote forwarding server.

Adding a web proxy forwarding server

To add a forwarding server, select **Create New** in the **Web Proxy Forwarding Servers** section of the **Explicit Proxy** page by going to **Network > Explicit Proxy**.

Server Name	Enter the name of the forwarding server.
Proxy Address	Enter the IP address of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an FQDN or IP address.

Port	Enter the port number on which the proxy receives connections. Traffic leaving the FortiGate explicit web proxy for this server has its destination port number changed to this number.
Server Down action	<p>Select what action the explicit web proxy to take if the forwarding server is down.</p> <p>Block means if the remote server is down block traffic.</p> <p>Use Original Server means do not forward traffic to the forwarding sever but instead forward it from the FortiGate to its destination. In other words operate as if there is no forwarding server configured.</p>
Enable Health Monitor	Select to enable health check monitoring and enter the address of a remote site. See “Web proxy forwarding server monitoring and health checking” .
Health Check Monitor Site	

Use the following CLI command to add a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port 8080.

```
config web-proxy forward-server
  edit fwd-srv
    set addr-type fqdn
    set fqdn proxy.example.com
    set port 8080
  end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. If the remote server does not respond it is assumed to be down. Checking continues and when the server does send a response the server is assumed to be back up. If you configure health checking, every 10 seconds the FortiGate unit attempts to get a response from a web server by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

Configure the server down action and enable health monitoring from the web-based manager by going to **Network > Explicit Proxy**, selecting a forwarding server, and changing the server down action and changing the health monitor settings.

Use the following CLI command to enable health checking for a web proxy forwarding server and set the server down option to bypass the forwarding server if it is down.

```
config web-proxy forward-server
  edit fwd-srv
    set healthcheck enable
    set monitor http://example.com
    set server-down-option pass
  end
```

Grouping forwarding servers and load balancing traffic to them

You can add multiple web proxy forwarding servers to a forwarding server group and then add the server group to an explicit web proxy policy instead of adding a single server. Forwarding server groups are created from the FortiGate CLI but can be added to policies from the web-based manager (or from the CLI).

When you create a forwarding server group you can select a load balancing method to control how sessions are load balanced to the forwarding servers in the server group. Two load balancing methods are available:

- **Weighted** load balancing sends more sessions to the servers with higher weights. You can configure the weight for each server when you add it to the group.
- **Least-session** load balancing sends new sessions to the forwarding server that is processing the fewest sessions.

When you create a forwarding server group you can also enable **affinity**. Enable affinity to have requests from the same client processed by the same server. This can reduce delays caused by using multiple servers for a single multi-step client operation. Affinity takes precedence over load balancing.

You can also configure the behavior of the group if all of the servers in the group are down. You can select to **block** traffic or you can select to have the traffic **pass** through the FortiGate explicit proxy directly to its destination instead of being sent to one of the forwarding servers.

Use the following command to add a forwarding server group that uses weighted load balancing to load balance traffic to three forwarding servers. Server weights are configured to send most traffic to server2. The group has affinity enabled and blocks traffic if all of the forward servers are down:

```
config web-proxy forward-server
  edit server_1
    set ip 172.20.120.12
    set port 8080
  next
  edit server_2
    set ip 172.20.120.13
    set port 8000
  next
  edit server_3
    set ip 172.20.120.14
    set port 8090
  next
end
config web-proxy forward-server-group
  edit New-fwd-group
    set affinity enable
    set ldb-method weight
    set group-down-option block
    config server-list
      edit server_1
        set weight 10
      next
      edit server_2
        set weight 40
      next
      edit server_3
        set weight 10
      next
    end
end
```

Adding proxy chaining to an explicit web proxy policy

You enable proxy chaining for web proxy sessions by adding a web proxy forwarding server or server group to an explicit web proxy policy. In a policy you can select one web proxy forwarding server or server group. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server or server group.

To add an explicit web proxy forwarding server - web-based manager:

1. Go to **Policy & Objects > Proxy Policy** and select **Create New**.
2. Configure the policy:

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT
Web Proxy Forwarding Server	Select, fwd-srv

3. Select **OK** to save the security policy.

To add an explicit web proxy forwarding server - CLI:

1. Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named `fwd-srv`

```
config firewall proxy-policy
edit 0
    set proxy explicit-web
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set schedule always
    set webproxy-forward-server fwd-srv
end
```

Security profiles, threat weight, device identification, and the explicit web proxy

You can apply all security profiles to explicit web proxy sessions. This includes antivirus, web filtering, intrusion protection (IPS), application control, data leak prevention (DLP), and SSL/SSH inspection. Security profiles are applied by selecting them in an explicit web proxy policy or in authentication rules added to web proxy policies.

Traffic accepted by explicit web proxy policies contributes to threat weight data.

The explicit web proxy is not compatible with device identification.

Since the traffic accepted by the explicit web proxy is known to be either HTTP, HTTPS, or FTP over HTTP and since the ports are already known by the proxy, the explicit web proxy does not use all of the SSL/SSH inspection options. The explicit web proxy does support the following proxy options:

- Enable chunked bypass
- HTTP oversized file action and threshold

The explicit web proxy does not support the following proxy options:

- Client comforting
- Server comforting
- Monitor content information from dashboard. URLs visited by explicit web proxy users are not added to dashboard usage and log and archive statistics widgets.

For explicit web proxy sessions, the FortiGate unit applies antivirus scanning to HTTP POST requests and HTTP responses. The FortiGate unit starts virus scanning a file in an HTTP session when it receives a file in the body of an HTML request. The explicit web proxy can receive HTTP responses from either the originating web server or the FortiGate web cache module.

Explicit web proxy sessions and user limits

Web browsers and web servers open and close multiple sessions with the explicit web proxy. Some sessions open and close very quickly. HTTP 1.1 keepalive sessions are persistent and can remain open for long periods of time. Sessions can remain on the explicit web proxy session list after a user has stopped using the proxy (and has, for example, closed their browser). If an explicit web proxy session is idle for more than 3600 seconds it is torn down by the explicit web proxy. See [RFC 2616](#) for information about HTTP keepalive/persistent HTTP sessions.

This section describes proxy sessions and user limits for both the explicit web proxy and the explicit FTP proxy. Session and user limits for the two proxies are counted and calculated together. However, in most cases if both proxies are active there will be many more web proxy sessions than FTP proxy sessions.

The FortiGate unit adds two sessions to its session table for every explicit proxy session started by a web browser and every FTP session started by an FTP client. An entry is added to the session table for the session from the web browser or client to the explicit proxy. All of these sessions have the same destination port as the explicit web proxy port (usually 8080 for HTTP and 21 for FTP). An entry is also added to the session table for the session between the exiting FortiGate interface and the web or FTP server destination of the session. All of these sessions have a FortiGate interface IP address and the source address of the session and usually have a destination port of 80 for HTTP and 21 for FTP.

Proxy sessions that appear in FortiView do not include the Policy ID of the web-proxy or ftp-proxy security policy that accepted them. However, the explicit proxy sessions include a destination port that matches the explicit proxy port number (usually 8080 for the web proxy and 21 for the FTP proxy). The proxied sessions from the FortiGate unit have their source address set to the IP address of the FortiGate unit interface that the sessions use to connect to their destinations (for example, for connections to the Internet the source address would be the IP address of the FortiGate interface connected to the Internet).

FortiOS limits the number of explicit proxy users. This includes both explicit FTP proxy and explicit web proxy users. The number of users varies by FortiGate model from as low as 10 to up to 18000 for high end models. You cannot raise this limit.

If your FortiGate unit is configured for multiple VDOMs you can go to **System > Global Resources** to view the maximum number of **Concurrent explicit proxy users** and optionally reduce the limit. You can also use the following command:

```
config global
```

```
config system resource-limits
    set proxy 50
end
end
```

To limit the number of explicit proxy users for a VDOM, from the web-based manager enable multiple VDOMs and go to **System > VDOM** and edit a VDOM or use the following command to change the number of explicit web proxy users for VDOM_1:

```
config global
    config system vdom-property
        edit VDOM_1
            set proxy 25
        end
    end
end
```

You can use the `diagnose wad user list` command to view the number of explicit web proxy users. Users may be displayed with this command even if they are no longer actively using the proxy. All idle sessions time out after 3600 seconds.

You can use the command `diagnose wad user clear` to clear current explicit proxy users. You can also use the command `diagnose wad user clear <user-name>` to clear individual users. This means delete information about all users and force them re-authenticate.

Users that authenticate with explicit web-proxy or ftp-proxy security policies do not appear in the **Monitor > Firewall User Monitor** list and selecting **De-authenticate All Users** has no effect on explicit proxy users.

How the number of concurrent explicit proxy users is determined depends on their authentication method:

- For session-based authenticated users, each authenticated user is counted as a single user. Since multiple users can have the same user name, the proxy attempts to identify users according to their authentication membership (based upon whether they were authenticated using RADIUS, LDAP, FSAE, local database etc.). If a user of one session has the same name and membership as a user of another session, the explicit proxy assumes this is one user.
- For IP Based authentication, or no authentication, or if no web-proxy security policy has been added, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

The explicit proxy does not limit the number of active sessions for each user. As a result the actual explicit proxy session count is usually much higher than the number of explicit web proxy users. If an excessive number of explicit web proxy sessions is compromising system performance you can limit the amount of users if the FortiGate unit is operating with multiple VDOMs.

Explicit proxy configuration

The following is information that is specific to Explicit Proxy configuration. Any configuration information that is common to Web Proxy in general is covered in the more inclusive section of [Web proxy configuration on page 855](#).

Configuring an external IP address for the IPv4 explicit web proxy

You can use the following command to set an external IP address (or pool) that will be used by the explicit web proxy policy.

```
config web-proxy explicit
    set status enable
    set outgoing-ip <ip1> <ip2> ... <ipN>
end
```

Configuring an external IP address for the IPv6 explicit web proxy

You can use the following command to set an external IP address (or pool) that will be used by the explicit web proxy policy.

```
config web-proxy explicit
    set status enable
    set outgoing-ipv6 <ip1> <ip2> ... <ipN>
end
```

Restricting the IP address of the IPv4 explicit web proxy

You can use the following command to restrict access to the explicit web proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit web proxy:

```
config web-proxy explicit
    set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the IPv4 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config web-proxy explicit
    set outgoing-ip 172.20.120.100
end
```

Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy to use only one IPv6 IP address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require users to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 web proxy:

```
config web-proxy explicit
  set incoming-ipv6 2001:db8:0:2::30
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config web-proxy explicit
  set outgoing-ipv6 2001:db8:0:2::50
end
```

Explicit proxy firewall address types

Explicit proxy firewall address types improve granularity over header matching for explicit web proxy policies. You can enable this option using the **Show in Address List** button on the Address and Address Group New/Edit forms under **Policy & Objects > Addresses**.

The following address types are available:

- **URL Pattern** - destination address
- **Host Regex Match** - destination address
- **URL Category** - destination address (URL filtering)
- **HTTP Method** - source address
- **User Agent** - source address
- **HTTP Header** - source address
- **Advanced (Source)** - source address (combines User Agent, HTTP Method, and HTTP Header)
- **Advanced (Destination)** - destination address (combines Host Regex Match and URL Category)

Proxy auto-config (PAC) configuration

A proxy auto-config (PAC) file defines how web browsers can choose a proxy server for receiving HTTP content. PAC files include the FindProxyForURL(url, host) JavaScript function that returns a string with one or more access method specifications. These specifications cause the web browser to use a particular proxy server or to connect directly.

To configure PAC for explicit web proxy users, you can use the port that PAC traffic from client web browsers use to connect to the explicit web proxy. explicit web proxy users must configure their web browser's PAC proxy settings to use the PAC port.

PAC file content

You can edit the default PAC file from the web-based manager or use the following command to upload a custom PAC file:

```
config web-proxy explicit
    set pac-file-server-status enable
    set pac-file-data <pac_file_str>
end
```

Where <pac_file_str> is the contents of the PAC file. Enter the PAC file text in quotes. You can copy the contents of a PAC text file and paste the contents into the CLI using this option. Enter the command followed by two sets of quotes then place the cursor between the quotes and paste the file content.

The maximum PAC file size is 256 kbytes. If your FortiGate unit is operating with multiple VDOMs each VDOM has its own PAC file. The total amount of FortiGate memory available to store all of these PAC files 2 MBytes. If this limit is reached you will not be able to load any additional PAC files.

You can use any PAC file syntax that is supported by your users's browsers. The FortiGate unit does not parse the PAC file.

To use PAC, users must add an automatic proxy configuration URL (or PAC URL) to their web browser proxy configuration. The default FortiGate PAC file URL is:

```
http://<interface_ip>:<PAC_port_int>/<pac_file_str>
```

For example, if the interface with the explicit web proxy has IP address 172.20.120.122, the PAC port is the same as the default HTTP explicit web proxy port (8080) and the PAC file name is proxy.pac the PAC file URL would be:

```
http://172.20.120.122:8080/proxy.pac
```

From the CLI you can use the following command to display the PAC file URLs:

```
get web-proxy explicit
```

Unknown HTTP version

You can select the action to take when the proxy server must handle an unknown HTTP version request or message. Set unknown HTTP version to Reject or Best Effort. Best Effort attempts to handle the HTTP traffic as best as it can. Reject treats known HTTP traffic as malformed and drops it. The Reject option is more secure.

Authentication realm

You can enter an authentication realm to identify the explicit web proxy. The realm can be any text string of up to 63 characters. If the realm includes spaces enclose it in quotes. When a user authenticates with the explicit web proxy the HTTP authentication dialog includes the realm so you can use the realm to identify the explicitly web proxy for your users.

Implementing botnet features

The option `scan-botnet-connections` can be added to an explicit proxy policy.

CLI Syntax:

```
config firewall proxy-policy
```

```
edit <policy_id>
  set scan-botnet-connections [disable|block|monitor]
end
```

where:

- `disable` means do not scan connections to botnet servers.
- `block` means block connections to botnet servers.
- `monitor` means log connections to botnet servers.

Adding disclaimer messages to explicit proxy policies

This feature allows you to create user exceptions for specific URL categories (including warning messages) based on user groups. The **Disclaimer Options** are configured under **Policy & Objects > Proxy Policy**.

You can also configure a disclaimer for each Authentication Rule by setting **Action** to **Authenticate**.

Disclaimer explanations

- **Disable:** No disclaimer (default setting).
- **By Domain:** The disclaimer will be displayed on different domains. The explicit web proxy will check the referring header to mitigate the javascript/css/images/video/etc page.
- **By Policy:** The disclaimer will be displayed if the HTTP request matches a different explicit firewall policy.
- **By User:** The disclaimer will be displayed when a new user logs on.

Changing HTTP headers

You can create explicit web proxy profiles that can add, remove and change HTTP headers. The explicit web proxy profile can be added to a web explicit proxy policy and will be applied to all of the HTTP traffic accepted by that policy.

You can change the following HTTP headers:

- client-ip
- via header for forwarded requests
- via header for forwarded responses
- x-forwarded-for
- front-end-https

For each of these headers you can set the action to:

- Pass to forward the traffic without changing the header
- Add to add the header
- Remove to remove the header

You can also configure how the explicit web proxy handles custom headers. The proxy can add or remove custom headers from requests or responses. If you are adding a header you can specify the content to be included in the added header.

Create web proxy profiles from the CLI:

```
config web-proxy profile
edit <name>
  set header-client-ip {add | pass | remove}
```

```
set header-via-request {add | pass | remove}
set header-via-response {add | pass | remove}
set header-x-forwarded-for {add | pass | remove}
set header-front-end-https {add | pass | remove}
config headers
  edit <id>
    set action {add-to-request | add-to-response | remove-from-request |
              remove-from-response}
    set content <string>
    set name <name>
  end
end
```

Use the following command to add a web proxy profile to an explicit proxy policy:

```
config firewall proxy-policy
  edit <id>
    set webproxy-profile <name>
  end
```

Preventing the explicit web proxy from changing source addresses

By default in NAT/Route mode the explicit web proxy changes the source address of packets leaving the FortiGate to the IP address of the FortiGate interface that the packets are exiting from. In transparent mode the source address is changed to the management IP.

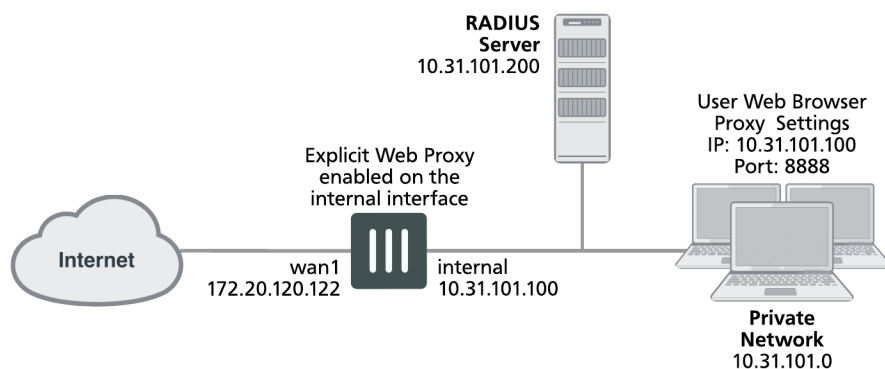

This configuration hides the IP addresses of clients and allows packets to return to the FortiGate unit interface without having to route packets from clients. You can use the following command to configure the explicit web proxy to keep the original client's source IP address:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    set transparent enable
  end
```

Example users on an internal network browsing the Internet through the explicit web proxy with web caching, RADIUS authentication, web filtering, and virus scanning

This example describes how to configure the explicit web proxy for the example network shown below. In this example, users on the internal network connect to the explicit web proxy through the Internal interface of the FortiGate unit. The explicit web proxy is configured to use port 8888 so users must configure their web browser proxy settings to use port 8888 and IP address 10.31.101.100.

Example explicit web proxy network topology

Explicit web proxy users must authenticate with a RADIUS server before getting access to the proxy. The explicit proxy policy that accepts explicit web proxy traffic applies per session authentication and includes a RADIUS server user group. The authentication rule also applies web filtering and virus scanning.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit web proxy for HTTP and HTTPS and change the HTTP and HTTPS ports to 8888.
2. Enable the explicit web proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit web proxy.
4. Add an authentication explicit proxy policy. Enable web caching. Add an authentication rule and enable antivirus and web filtering.

Configuring the explicit web proxy - web-based manager

Use the following steps to configure the explicit web proxy.

To enable and configure the explicit web proxy

1. Go to **System > Feature Visibility** and turn on the **Explicit Proxy** feature.
2. Go to **Network > Explicit Proxy** and change the following settings:

Enable Explicit Web Proxy	Select HTTP/HTTPS .
Listen on Interfaces	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
HTTP Port	8888
HTTPS Port	0
Realm	You are authenticating with the explicit web proxy.
Default Firewall Policy Action	Deny

3. Select **Apply**.

To enable the explicit web proxy on the Internal interface

1. Go to **Network > Interfaces**.
2. Edit the internal interface.
3. Select **Enable Explicit Web Proxy**.
4. Select **OK**.

To add a RADIUS server and user group for the explicit web proxy

1. Go to **User & Device > RADIUS Servers** and select **Create New** to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

2. Select **OK**.
3. Go to **User & Device > User Groups** and select **Create New** to add a new user group.

Name	Explicit_proxy_user_group
Type	Firewall
Remote Groups	RADIUS_1
Group Name	Any

4. Select **OK**.

To add an explicit proxy policy

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Add a firewall address for the internal network:

Category	Address
Name	Internal_subnet
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.0
Interface	Any

3. Go to **Policy & Objects > Proxy Policy** and select **Create New**.
4. Configure the explicit web proxy policy.

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

- Under **Configure Authentication Rules** select **Create New** to add an authentication rule:

Groups	Explicit_policy
Source User(s)	Leave blank
Schedule	always

- Turn on **Antivirus** and **Web Filter** and select the **default** profiles for both.
- Select the **default** proxy options profile.
- Select **OK**.
- Make sure **Enable IP Based Authentication** is not selected.
- Turn on **Web Cache**.
- Select **OK**.

Configuring the explicit web proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable the explicit web proxy on the Internal interface

- Enter the following command to enable the explicit web proxy on the internal interface.

```
config system interface
  edit internal
    set explicit-web-proxy enable
  end
```

To enable and configure the explicit web proxy

- Enter the following command to enable the explicit web proxy and set the TCP port that proxy accepts HTTP and HTTPS connections on to 8888.

```
config web-proxy explicit
  set status enable
  set http-incoming-port 8888
  set https-incoming-port 8888
  set realm "You are authenticating with the explicit web proxy"
  set sec-default-action deny
end
```

To add a RADIUS server and user group for the explicit web proxy

- Enter the following command to add a RADIUS server:

```
config user radius
```

```
edit RADIUS_1
  set server 10.31.101.200
  set secret RADIUS_server_secret
end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
  edit Explicit_proxy_user_group
    set group-type firewall
    set member RADIUS_1
  end
```

To add a security policy for the explicit web proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

2. Enter the following command to add the explicit web proxy security policy:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    set dstintf wan1
    set srcaddr Internal_subnet
    set dstaddr all
    set action accept
    set service webproxy
    set webcache enable
    set identity-based enable
    set ipbased disable
    set active-auth-method basic
    set groups <User group>
  end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit web proxy configuration is working as expected:

To test the explicit web proxy configuration

1. Configure a web browser on the internal subnet to use a web proxy server at IP address 10.31.101.100 and port 8888.
2. Browse to an Internet web page.
The web browser should pop up an authentication window that includes the phrase that you added to the Realm option.
3. Enter the username and password for an account on the RADIUS server.
If the account is valid you should be allowed to browse web pages on the Internet.
4. Close the browser and clear its cache and cookies.
5. Restart the browser and connect to the Internet.
You could also start a second web browser on the same PC. Or you could start a new instance of the same

browser as long as the browser asks for a user name and password again.

You should have to authenticate again because identity-based policies are set to session-based authentication.

6. If this basic functionality does not work, check your FortiGate and web browser configuration settings.
7. Browse to a URL on the URL filter list and confirm that the web page is blocked.
8. Browse to <http://eicar.org> and attempt to download an anti-malware test file.

The antivirus configuration should block the file.

Sessions for web-proxy security policies do not appear on the Top Sessions dashboard widget and the count column for security policies does not display a count for explicit web proxy security policies.

9. You can use the following command to display explicit web proxy sessions

```
get test wad 60
IP based users:

Session based users:
  user:0x9c20778, username:User1, vf_id:0, ref_cnt:9

Total allocated user:1

Total user count:3, shared user quota:50, shared user count:3
```

This command output shows one explicit proxy user with user name `User1` authenticated using session-based authentication.

Kerberos and NTLM authentication

FortiOS recognizes the client's authentication method from the token and selects the correct authentication scheme to authenticate successfully.

CLI syntax

```
config firewall proxy-policy
  edit 0
    set active-auth-method [ntlm|basic|digest|negotiate|none]
  end
```

Kerberos authentication for explicit proxy users

Kerberos authentication is a method for authenticating both explicit web proxy and transparent web proxy users. It has several advantages over NTLM challenge response:

- Does not require FSSO/AD agents to be deployed across domains.
- Requires fewer round-trips than NTLM SSO, making it less latency sensitive.
- Is (probably) more scalable than challenge response.
- Uses existing Windows domain components rather than added components.
- NTLM may still be used as a fallback for non-Kerberos clients.

Enhancements to Kerberos explicit and transparent web proxy

FortiOS 5.6.x authentication is managed by schemes and rules based on protocol and source address. As such, configurable authentication settings have been introduced to enhance authentication.

CLI commands (`config authentication rule, scheme, and setting`) allow explicit proxy rules and schemes to be created to separate user authentication (e.g. authentication rules and schemes used to match conditions in order to identify users) from user authorization (proxy-based policies with users and/or user groups).

CLI syntax - config authentication rule

```
config authentication rule
edit <name>
    set name <name>
    set status {enable|disable}
    set protocol {http|ftp|socks}
    config srcaddr <addr-name or addrgrp-name>
        edit <name>
            set name <ipv4-policy-name>
        next
    end
    config srcaddr6 <addr-name or addrgrp-name>
        edit <name>
            set name <ipv6-policy-name>
        next
    end
    set ip-based {enable|disable}
    set active-auth-method <scheme-name>
    set sso-auth-method <scheme-name>
    set transaction-based {enable|disable} - basic scheme + session-based
    set web-auth-cookie {enable|disable}
    set comments <comments>
next
end
```

Note: As shown above, HTTP, FTP, and SOCKSV5 authentication protocols are supported for explicit proxy.

Authentication rules are used to receive user-identity, based on the values set for protocol and source address. Having said this, if a rule fails to match based on source address, there will be no other attempt to match the rule, however the next policy will be attempted. This occurs only when:

- there is an authentication rule, but no authentication method has been set (under `config authentication scheme`; see below), so user identity cannot be found.
- the user is successfully matched in the rule, but fails to match the current policy.

Once a rule is positively matched through protocol and/or source address, it must also match the authentication method specified (`active-auth-method` and `sso-auth-method`). These methods point to schemes, as defined under `config authentication scheme`.

CLI syntax - config authentication scheme

```
config authentication scheme
edit <name>
    set name <name>
    set method {basic|digest|ntlm|form|negotiate|fsso|rsso}
    set negotiate-ntlm {enable|disable}
    set require-tfa {enable|disable}
    set fsso-guest {enable|disable}
    config user-database
        edit <name>
            set name {local|<ldap-server>|<radius-server>|<fsso-name>|<rsso-name>|<tacacs+-name>}
        next
    end
end
```

```

        next
    end
    next
end

```

Combining authentication rules and schemes, granular control can be exerted over users and IPs, creating an efficient process for users to successfully match a criteria before matching the policy.

Additional options can be set under `config authentication setting`.

CLI syntax - config authentication setting

```

config authentication setting
    set sso-scheme <scheme-name>
    set active-scheme <scheme-name>
    set captive-portal <host-name>
    set captive-portal-port <tcp-port>
end

```

Integration of transparent and explicit proxy HTTP policy checking

A CLI command, under `config firewall profile-protocol-options`, allows HTTP policy checking to be enable or disabled. When enabled, transparent traffic can be matched in a firewall policy and policy user authentication can occur. In addition, separate SSL inspection policies can be created:

```

config firewall profile-protocol-options
    edit <name>
        set http-policy {enable|disable}
    end

```

Internet Service Database in Explicit/Implicit proxy policies

CLI commands, under `config firewall proxy-policy`, implement the Internet Service Database (ISDB) as the webproxy matching factor, and override IP pool is also support:

```

config firewall proxy-policy
    edit <name>
        set proxy {explicit-web|transparent-web|ftp|wanopt}
        set dstintf <dst-name>
        set poolname <ip-pool-name>
    end

```

Multiple port/port range support for explicit web and explicit FTP proxy

Multiple port numbers and/or ranges can be set for explicit proxy, specifically for HTTP/HTTPS and FTP. Go to **Network > Explicit Proxy** and configure settings under **Explicit Web Proxy** and **Explicit FTP Proxy**, or under `config web-proxy explicit` in the CLI Console.

1. General configuration

1.1 Kerberos environment - Windows server setup

1. Build a Windows 2008 Platform server.
2. Enable domain configuration in windows server (dcpromo).
3. Set the domain name TEST.COM (realm name).

1.2 Create users

- *testuser* is a normal user (could be any existing domain user account).
- *testfgt* is the service name. In this case it should be the FQDN for the explicit proxy Interface, For example the hostname in the client browser proxy config.
- Recommendation: create username all in lowercase (even if against corporate standards).
 - The account only requires “domain users” membership
 - Password set to never expire
 - Set a very strong password

1.3 Add FortiGate to DNS

Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa

For Lab/Testing add the FortiGate Domain name and IP mapping in the hosts file (windows/system32/drivers/etc/hosts). e.g., `TESTFGT.TEST.COM 10.10.1.10`

1.4 Generate the Kerberos keytab

Use the *ktpass* command (found on Windows Servers and many domain workstations) to generate the Kerberos keytab.

Example:

```
ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser testfgt -pass <password> -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

In the case where the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

The ktpass on older Windows servers (i.e. 2003) may not support the “all” crypto option.

Example:

```
ktpass -princ HTTP/testfgt.test.com@TEST.COM -mapuser testfgt -pass 12345678 -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

The realm name is always presented in uppercase, and prefixed with the “@” character.

1.5 Encode base64

Use the *base64* command (available in most Linux distros) command to encode the *fgt.keytab* file. Any LF (Line Feed) need to be deleted from the file.

Example:

```
base64 fgt.keytab > fgt.txt
```

Use Notepad++ or some native Linux text editor. Windows Notepad and Wordpad are likely to introduce errors.

2. FortiGate configuration

2.1 Create LDAP server instance

```
config user ldap
  edit "ldap" <<< Required for authorization
    set server "10.10.1.1" <<< LDAP server IP, normally it should be same as KDC server
    set cnid "cn"
    set dn "dc=test,dc=com"
    set type regular
    set username "CN=admin,CN=Users,DC=test,DC=com" <<< Your domain may require STARTTLS
    set password <FOOS>
  next
end
```

2.2 Define Kerberos as an authentication service

```
config user krb-keytab
  edit "http_service"
    set principal "HTTP/testfgt.test.com@TEST.COM" <<< Same as the principal name in 1.4
    set ldap-server "ldap" <<< the defined ldap server for authorization
    set keytab
      "BQIAAABNAAIACKJFUKJFUi5DT00ABEhUVFAAGlRPTllfRkdUXzEwMERfQS5CRVJCRVIuQ09NAAAAQA
      AAAAKABcAEJQl0MHgovwplu7XzfENJzw=" <<< base64 encoding keytab data, created in step 1.5
  next
end
```

2.3 Create user group(s)

```
config user group <<< the group is used for kerberos authentication
  edit "testgrp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap" <<< Same as ldap-server option in krb-keytab
        set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
      next
    end
  next
end
```

2.4 Create firewall policy

```
config firewall proxy-policy
  edit 1
    set uuid 5e5dd6c4-952c-51e5-b363-120ad77c1414
    set proxy explicit-web
    set dstintf "port1"
```

```

        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set groups "CN=USERS LAB.PS FSSO"
    next
end

```

2.5 Diagnostics

Once the keytab is imported, check that it has been properly decoded. The filename generated will be relatively random, but should be clearly visible.

```

Artoo-Deetoo (root) # fnsysctl ls -la /tmp/kt
drwxr--r-- 2 0 0 Fri Dec 2 10:06:43 2016 60 .
drwxrwxrwt 22 0 0 Tue Dec 6 14:28:29 2016 3280 ..
-rw-r--r-- 1 0 0 Fri Dec 2 10:06:43 2016 392 1.0.89.keytab

```

If there is no file present, then the file hasn't decoded. Check the file for line feeds and try again.

3. Client side walkthrough

3.1 Check Kerberos is working

Log on to the domain by using *testuser*, created in 1.2. Use the *klist* command to list ticket information. In the below example, the client has received *krbtgt*, *CIFS*, and *LDAP* tickets. As there has been no interaction with the FortiGate, there are no references to it.

```

C:\Users\glenk>klist
Cached Tickets: (5)

C:\Users\glenk>klist

```

3.2 Configure client

Set up web-proxy in browser through the FortiGate. This can be achieved via a PAC file or direct browser configuration.

Some Firefox documentation indicates that it is necessary to make manual advanced configuration changes to allow Kerberos authentication work. However, builds 48 (and possibly much earlier) require no additional configuration beyond setting of the proxy server.

3.3 Open a connection to the Internet

1. The client accesses the explicit proxy, but a *HTTP 407 Proxy Authentication Required* is returned.
2. As “Negotiate” is set, the client has knowledge of the KRBtgt, it requests a ticket from the KDC with a *krb-tgs-req* message. This includes the REALM (HOME.LOCAL) in the *req-body* section, and the provided instances SNAME and service (in this case, HTTP/artoo-deetoo.home.local).
3. The KDC responds with a next KRB-TGS-REP.

This ticket is then available on the client.

In the example below, the ticket-granted-service has issued Ticket #2.

```
#2> Client: glenk @ home.local
Server: HTTP/artoo-deetoo.home.local @ HOME.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC (NT)
Ticket Flags 0x40a00000 -> forwardable renewable pre_authent
Start Time: 12/6/2016 14:59:45 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: RSADSI RC4-HMAC (NT)
```

4. The conversation between the client and the proxy continues, as the client responds with the Kerberos ticket in the response.

The whole process takes less than a second to complete. The user should be visible as a FSSO logon in the Web UI.

Transparent web-proxy Kerberos authentication

Transparent web-proxy allows the FortiGate to process level 7 policy matching, even when the explicit web-proxy is not enabled on the client's browser. The transparent web-proxy policy is set in proxy-policy too. The policy matching rule is the same as the explicit web-proxy.

In the firewall policy level, transparent web-proxy is regarded as a special UTM. The HTTP/HTTPS traffic matches the firewall policy first, then traffic is redirected to the web-proxy daemon. If the transparent web-proxy feature is disabled, http-policy options in profile-protocol-options is used to enable transparent web-proxy feature.

IP-based

Kerberos authentication requires the captive portal to be an FQDN address that is resolved to a local IP address. However, it becomes more complicated to setup an FQDN address in a local user deployment. Therefore you can set the `captive-portal-type` to either use an FQDN or IP address.

1. Captive portal and the captive portal port must be configured in transparent web-proxy for support of Kerberos authentication:

```
config authentication setting
    set captive-portal-type {fqdn | ip}
    set captive-portal <fqdn-name> / <ip>
    set captive-portal-port "9998"
end
```

2. Authentication rule, scheme, and krb-keytab need to be configured for Kerberos authentication (note the `active-auth-method` scheme referenced in the rule):

```
config authentication scheme
    edit <kerberos-scheme>
        set method negotiate
        set negotiate-ntlm <enable>
        set fsso-guest <disable>
    next
end

config authentication rule
    edit <name>
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <enable>
        set active-auth-method <kerberos-scheme>
    next
end

config user krb-keytab
    edit <name>
        set principal "HTTP/TESTFGT.TEST.COM@TEST.COM"
        set ldap-server "ldap"
```

```

        set keytab <base64-encoding-keytab-data>
    next
end

```

3. Configure LDAP and user group used for authorization:

```

config user ldap
    edit "ldap"
        set server "10.10.1.1"
        set cnid
        srt dn
        set type <regular>
        set username "CN=admin,CN=Users,DC=test,DC=com"
        set password ENC
            aW51IAHkPMf4D+ZCKpGMU3x8Fpq0G+7uIbAvpblbXFA5vLfGb4/oRBx+B6R/v+CMCetP84e+Gdz5zEcM
            yOd3cj0BoIhFrpYJfXhRs4lSEOHezeVXfxwTSf5VJG+F11G/G5RpaY+AE8bortC8MBe7P2/uGQocFHu4
            Ilulp5I60Jvyk6Ei3hDZMjTd8iPp5IkRJZVVjQ==
    next
end

config user group
    edit "testgrp"
        set member "ldap"
        config match
            edit "1"
                set server-name "ldap"
                set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
            next
        end
    next
end

```

4. Create proxy-policy, with groups as the authorizing policy-matching element:

```

config firewall proxy-policy
    edit 1
        set uuid 1bbb891a-9cd2-51e7-42ff-d1fa13cac3da
        set proxy explicit-web
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set groups testgrp
    next
end

```

5. UTM must be enabled in the firewall policy to support the transparent web-proxy:

```

config firewall policy
    edit "1"
        set name "policy1"
        set uuid 8a6ceeac-b016-51e6-2b5c-165070d5bf50
        set srcintf "mgmt1"
        set dstintf "mgmt1"
        set srcaddr "all"
        set dstaddr "all"
        set action <accept>
    next
end

```

```
        set schedule "always"
        set service "ALL"
        set utm-status <enable>
        set profile-protocol-options "transparent-web-proxy"
        set ssl-ssh-profile "deep-inspection"
        set nat <enable>
    next
end

config firewall profile-protocol-options
    edit "transparent-web-proxy"
        config http
            set ports "80 8080"
            unset options
            set http-policy enable
            unset post-lang
        end
        ...
    next
end
```

Session-based with web-auth cookie

The web-auth-cookie feature is necessary for session-based authentication under transparent web-proxy.

The configuration is the same as for IP-based authentication, except `ip-based` is disabled in the authentication rule:

```
config authentication rule
    edit "kerberos-rules"
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <disable>
        set active-auth-method <kerberos-scheme>
    next

config authentication setting
    set captive-portal <fqdn-name>
    set captive-portal-port "9998"
end
```

Transparent proxy concepts

In addition to the Explicit Web Proxy, FortiOS supports a Transparent web proxy. While it does not have as many features as Explicit Web Proxy, the transparent proxy has the advantage that nothing needs to be done on the user's system to forward supported web traffic over to the proxy. There is no need to reconfigure the browser or publish a PAC file. Everything is transparent to the end user, hence the name. This makes it easier to incorporate new users into a proxy deployment.

You can use the transparent proxy to apply web authentication to HTTP traffic accepted by a firewall policy. In previous versions of FortiOS, web authentication required using the explicit proxy.

Normal FortiOS authentication is IP address based. Users are authenticated according to their IP address and access is allowed or denied based on this IP address. On networks where authentication based on IP address will not work you can use the Transparent Web proxy to apply web authentication that is based on the user's browser and not on their IP address. This authentication method allows you to identify individual users even if multiple users on your network are connecting to the FortiGate from the same IP address.

More about the transparent proxy

The following changes are incorporated into Transparent proxy, some of which affect Explicit Web Proxy as well.

Flat policies

The split policy feature has been removed. This will make the explicit policy more like the firewall policy.

Authentication

The authentication design is intended to separate authentication from authorization. Authentication has been moved into a new table in the FortiOS. This leaves the authorization as the domain of the explicit proxy policy.

Previously, if authentication was to be used:

1. The policy would be classified as an identity based policy
2. The policy would be split to add the authentication parameters
3. The authentication method would be selected
4. The user/group would be configured

Now:

The user/group is configured in the proxy policy

1. A new authentication rule is added
2. This option refers to the authentication scheme
3. The authentication scheme has the details of the authentication method

The new authentication work flow for transparent proxy:

Toggle the transparent-http-policy match:

```
config firewall profile-protocol-options
edit <profile ID>
config http
```

```
set http-policy <enable|disable>
```

If disabled, everything works like before. If enabled, the authentication is triggered differently.

- http-policy work flow:
- For transparent traffic, if there is a regular firewall policy match, when the Layer 7 check option is enabled, traffic will be redirected to WAD for further processing.
- For redirected traffic, layer 7 policy (HTTP policy) will be used to determine how to do security checks.
- If the last matching factor is down to user ID, then it will trigger a new module to handle the L7 policy user authentication.
- Then propagate learned user information back to the system so that it can be used to match traffic for L4 policy.

New proxy type

There is a new subcategory of proxy in the proxy policy called **Transparent Web**. The old **Web Proxy** is now referred to as **Explicit Web Proxy**.

- This is set in the firewall policy
- It is available when the HTTP policy is enabled in the profile-protocol options for the firewall policy
- This proxy type supports OSI layer 7 address matching.
- This proxy type should include a source address as a parameter
- Limitations:
 - It can be used for HTTPS traffic, if deep scanning is not used
 - It only supports SNI address matching, i.e. domain names
 - It does not support header types of address matching
 - It only supports SSO authentication methods, no active authentication methods.

IP pools support

Proxies are now supported on outgoing IP pools.

SOCKSv5

SOCKSv5 authentication is now supported for explicit proxies.

To configure:

```
config authentication rule
  edit <name of rule>
    set protocol socks
  end
```

Forwarding

Proxies support URL redirect/forwarding. This allows a non-proxy forwarding server to be assigned a rule that will redirect web traffic from one URL to another, such as redirecting traffic destined for youtube.com to restrict.youtube.com.

- A new option called "Redirect URL" has been added to the policy
- Traffic forwarding by VIP is supported

Support for explicit proxy address objects & groups into IPv4 firewall policies

This would allow the selection of web filter policy, SSL inspection policy, and proxy policy based on source IP + destination (address|explicit proxy object|category|group of any of those). This enables things like “do full SSL interception on www.google.com, but not the rest of the Search Engines category”.

Support application service in the proxy based on HTTP requests.

The application service can be configured using the following CLI commands:

```
config firewall service custom
  edit <name of service>
    set explicit-proxy enable
    set app-service-type <disable|app-id|app-category>
    set app-category <application category ID, integer>
    set application <application ID, integer>
  end
```

Transparent proxy configuration

To implement the Transparent proxy, go to **System > Settings** and scroll down to **Operations Settings** and set the inspection mode to **Proxy**.

Operations Settings

Inspection Mode

Flow-based

Proxy

Virtual Domains ☐

Then go to **System > Feature Visibility** and enable **Explicit Proxy**.

Security Features

Feature Set: Custom

☒ Anti-Spam Filter +

<code>config firewall explicit-proxy-addrgrp</code>	<code>config firewall proxy-addrgrp</code>
<pre>config firewall explicit-proxy-policy edit <policy ID> set proxy web end</pre>	<pre>config firewall proxy-policy edit <policy ID> set proxy explicit-web end</pre>

FTP proxy concepts

The FortiGate explicit FTP proxy

You can use the FortiGate explicit FTP proxy to enable explicit FTP proxying on one or more FortiGate interfaces. The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

Explicit FTP proxies are configured for each VDOM when multiple VDOMs are enabled.

In most cases you would configure the explicit FTP proxy for users on a network by enabling the explicit FTP proxy on the FortiGate interface connected to that network. Users on the network would connect to and authenticate with the explicit FTP proxy before connecting to an FTP server. In this case the IP address of the explicit FTP proxy is the IP address of the FortiGate interface on which the explicit FTP proxy is enabled.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in transparent mode, users would configure their browsers to use a proxy server with the FortiGate unit management IP address.

The FTP proxy receives FTP sessions to be proxied at FortiGate interfaces with the explicit FTP proxy enabled. The FTP proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit FTP proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in transparent mode the explicit web proxy changes the source addresses to the management IP address.

Example explicit FTP proxy topology

To allow anyone to anonymously log into explicit FTP proxy and connect to any FTP server you can set the explicit FTP proxy default firewall proxy action to accept. When you do this, users can log into the explicit FTP proxy with any username and password.

In most cases you would want to use explicit proxy policies to control explicit FTP proxy traffic and apply security features, access control/authentication, and logging. You can do this by keeping the default explicit FTP proxy firewall policy action to deny and then adding explicit FTP proxy policies. In most cases you would also want users to authenticate with the explicit FTP proxy. By default an anonymous FTP login is required. Usually you would add authentication to explicit FTP proxy policies. Users can then authenticate with the explicit FTP proxy

according to users or user groups added to the policies. User groups added to explicit FTP proxy policies can use any authentication method supported by FortiOS including the local user database and RADIUS and other remote servers.

If you leave the default firewall policy action set to deny and add explicit FTP proxy policies, all connections to the explicit FTP proxy must match an or else they will be dropped. Sessions that are accepted are processed according to the ftp-proxy security policy settings.

You can also change the explicit FTP proxy default firewall policy action to accept and add explicit FTP proxy policies. If you do this, sessions that match explicit FTP proxy policies are processed according to the policy settings. Connections to the explicit FTP proxy that do not match an explicit FTP proxy policy are allowed and the users can authenticate with the proxy anonymously.

There are some limitations to the security features that can be applied to explicit FTP proxy sessions. See [The FortiGate explicit FTP proxy on page 899](#).

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit FTP proxy traffic. Explicit FTP proxy policies can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to **any**. (On the web-based manager you must set the interface to **Any**. In the CLI you must `unset the associated-interface`.)

How to use the explicit FTP proxy to connect to an FTP server

To connect to an FTP server using the explicit FTP proxy, users must run an FTP client and connect to the IP address of a FortiGate interface on which the explicit FTP proxy is enabled. This connection attempt must use the configured explicit FTP proxy port number (default 21).

The explicit FTP proxy is not compatible with using a web browser as an FTP client. To use web browsers as FTP clients configure the explicit web proxy to accept FTP sessions.

The following steps occur when a user starts an FTP client to connect to an FTP server using the explicit FTP proxy. Any RFC-compliant FTP client can be used. This example describes using a command-line FTP client. Some FTP clients may require a custom FTP proxy connection script.

1. The user enters a command on the FTP client to connect to the explicit FTP proxy.

For example, if the IP address of the FortiGate interface on which the explicit FTP proxy is enabled is 10.31.101.100, enter:

```
ftp 10.31.101.100
```

2. The explicit FTP proxy responds with a welcome message and requests the user's FTP proxy user name and password and a username and address of the FTP server to connect to:

```
Connected to 10.31.101.100.
220 Welcome to FortiGate FTP proxy
Name (10.31.101.100:user):
```

You can change the message by editing the FTP Explicit Banner Message replacement message.

3. At the prompt the user enters their FTP proxy username and password and a username and address for the FTP server. The FTP server address can be a domain name or numeric IP address. This information is entered using the following syntax:

```
<proxy-user>:<proxy-password>:<server-user>@<server-address>
```

For example, if the proxy username and password are `p-name` and `p-pass` and a valid username for the FTP server is `s-name` and the server's IP address is `ftp.example.com` the syntax would be:

```
p-name:p-pass:s-name@ftp.example.com
```

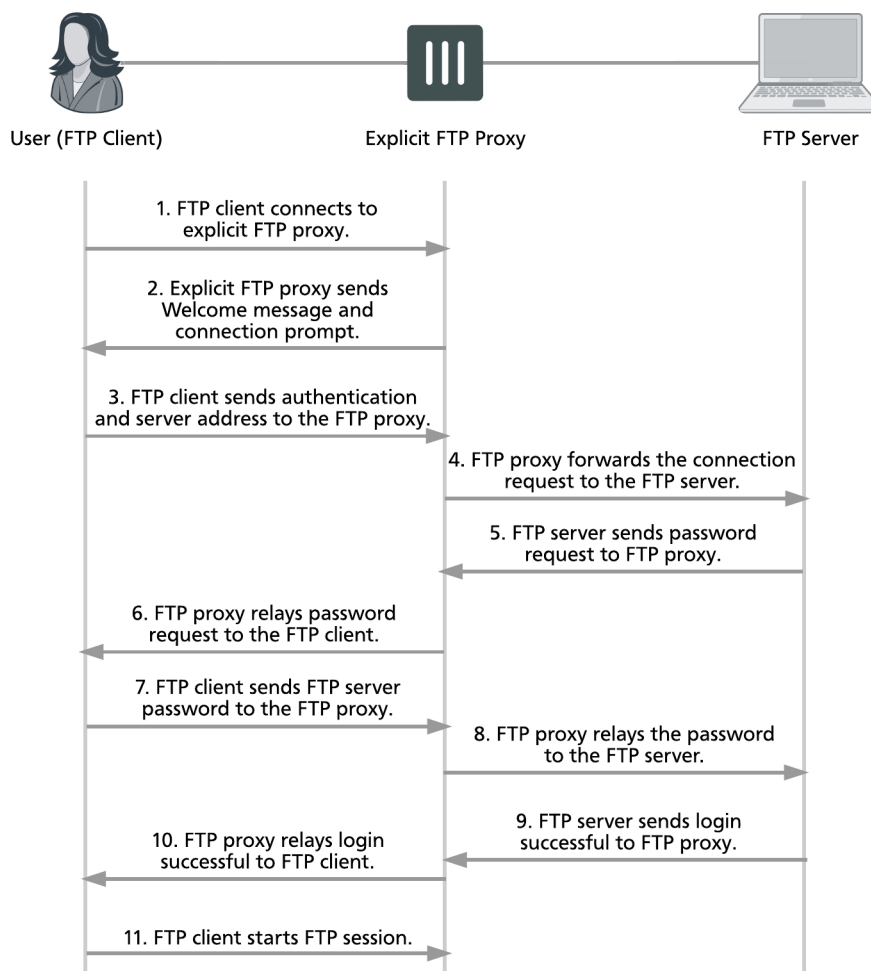

If the FTP proxy accepts anonymous logins `p-name` and `p-pass` can be any characters.

4. The FTP proxy forwards the connection request, including the user name, to the FTP server.
5. If the user name is valid for the FTP server it responds with a password request prompt.
6. The FTP proxy relays the password request to the FTP client.
7. The user enters the FTP server password and the client sends the password to the FTP proxy.
8. The FTP proxy relays the password to the FTP server.
9. The FTP server sends a login successful message to the FTP proxy.
10. The FTP proxy relays the login successful message to the FTP client.
11. The FTP client starts the FTP session.

All commands entered by the client are relayed by the proxy to the server. Replies from the server are relayed back to the FTP client.

Explicit FTP proxy session

From a simple command line FTP client connecting to an the previous sequence could appear as follows:

```
ftp 10.31.101.100 21
Connected to 10.31.101.100.
220 Welcome to FortiGate FTP proxy
Name (10.31.101.100:user): p-name:p-pass:s-name@ftp.example.com
331 Please specify the password.
Password: s-pass
230 Login successful.
Remote system type is UNIX
Using binary mode to transfer files.
ftp>
```

Security profiles, threat weight, device identification, and the explicit FTP proxy

You can apply antivirus, data leak prevention (DLP), and SSL/SSH inspection to explicit FTP proxy sessions. Security profiles are applied by selecting them in an explicit FTP proxy policy or an authentication rule in an FTP proxy security policy.

Traffic accepted by explicit FTP proxy policies contributes to threat weight data.

The explicit FTP proxy is not compatible with device identification.

Explicit FTP proxy options and SSL/SSH inspection

Since the traffic accepted by the explicit FTP proxy is known to be FTP and since the ports are already known by the proxy, the explicit FTP proxy does not use the FTP port proxy options settings.

When adding UTM features to an FTP proxy security policy, you must select a proxy options profile. In most cases you can select the default proxy options profile. You could also create a custom proxy options profile.

The explicit FTP proxy supports the following proxy options:

- Block Oversized File and oversized file limit

The explicit FTP proxy does not support the following protocol options:

- Client comforting

Explicit FTP proxy sessions and antivirus

For explicit FTP proxy sessions, the FortiGate unit applies antivirus scanning to FTP file GET and PUT requests. The FortiGate unit starts virus scanning a file in an FTP session when it receives a file in the body of an FTP request.

Flow-based virus scanning is not available for explicit FTP proxy sessions. Even if the FortiGate unit is configured to use flow-based antivirus, explicit FTP proxy sessions use the regular virus database.

Explicit FTP proxy sessions and user limits

FTP clients do not open large numbers of sessions with the explicit FTP proxy. Most sessions stay open for a short while depending on how long a user is connected to an FTP server and how large the file uploads or downloads are. So unless you have large numbers of FTP users, the explicit FTP proxy should not be adding large numbers of sessions to the session table.

Explicit FTP proxy sessions and user limits are combined with explicit web proxy session and user limits. For information about explicit proxy session and user limits, see [Explicit proxy sessions and user limits on page 1](#).

FTP proxy configuration

General explicit FTP proxy configuration steps

You can use the following general steps to configure the explicit FTP proxy.

To enable the explicit FTP proxy - web-based manager:

1. Go to **Network > Explicit Proxy > Explicit FTP Proxy Options**. Select **Enable Explicit FTP Proxy** to turn on the explicit FTP proxy.
2. Select **Apply**.

The **Default Firewall Policy Action** is set to **Deny** and requires you to add a explicit FTP proxy policy to allow access to the explicit FTP proxy. This configuration is recommended and is a best practice because you can use policies to control access to the explicit FTP proxy and also apply security features and authentication.

3. Go to **Network > Interfaces** and select one or more interfaces for which to enable the explicit web proxy. Edit the interface and select **Enable Explicit FTP Proxy**.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

4. Go to **Policy & Objects > Proxy Policy** and select **Create New** and set the **Explicit Proxy Type** to **FTP**.

You can add multiple explicit FTP proxy policies.

5. Configure the policy as required to accept the traffic that you want to be processed by the explicit FTP proxy.

The source address of the policy should match client source IP addresses. The firewall address selected as the source address cannot be assigned to a FortiGate interface. The Interface field of the firewall address must be blank or it must be set to **Any**.

The destination address of the policy should match the IP addresses of FTP servers that clients are connecting to. The destination address could be **all** to allow connections to any FTP server.

If **Default Firewall Policy Action** is set to Deny, traffic sent to the explicit FTP proxy that is not accepted by an explicit FTP proxy policy is dropped. If **Default Firewall Policy Action** is set to Allow then all FTP proxy sessions that don't match a policy are allowed.

For example the following explicit FTP proxy policy allows users on an internal network to access FTP servers on the Internet through the wan1 interface of a FortiGate unit.

Explicit Proxy Type	FTP
Source Address	Internal_subnet

Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT

The following explicit FTP proxy policy requires users on an internal network to authenticate with the FortiGate unit before accessing FTP servers on the Internet through the wan1 interface.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

6. Select **Create New** to add an **Authentication Rule** and configure the rule as follows:

Groups	Proxy-Group
Source Users	(optional)
Schedule	always

7. Add security profiles as required and select **OK**.
8. You can add multiple authentication rules to apply different authentication for different user groups and users and also apply different security profiles and logging settings for different users.
9. Select **OK**.

To enable the explicit FTP proxy - CLI:

1. Enter the following command to turn on the explicit FTP proxy. This command also changes the explicit FTP proxy port to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
end
```

The default explicit FTP proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit FTP proxy.

2. Enter the following command to enable the explicit FTP proxy for the internal interface.

```
config system interface
  edit internal
    set explicit-ftp-proxy enable
  end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit FTP proxy.

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

The source address for a ftp-proxy security policy cannot be assigned to a FortiGate unit interface.

4. Use the following command to add an explicit FTP proxy policy that allows all users on the internal subnet to use the explicit FTP proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
  edit 0
    set proxy ftp
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set schedule always
  end
```

5. Use the following command to add an explicit FTP proxy policy that allows authenticated users on the internal subnet to use the explicit FTP proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
  edit 0
    set proxy ftp
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr Fortinet-web-sites
    set action accept
    set schedule always
    set groups <User group>
  end
end
```

Restricting the IP address of the explicit FTP proxy

You can use the following command to restrict access to the explicit FTP proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require users to connect to the IP address 10.31.101.100 to connect to the explicit FTP proxy:

```
config ftp-proxy explicit
  set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the explicit FTP proxy

You can use the following command to restrict the source address of outgoing FTP proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config ftp-proxy explicit
  set outgoing-ip 172.20.120.100
end
```

Example users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning

This example describes how to configure the explicit FTP proxy for the example network shown below. In this example, users on the internal network connect to the explicit FTP proxy through the Internal interface with IP address 10.31.101.100. The explicit web proxy is configured to use port 2121 so to connect to an FTP server on the Internet users must first connect to the explicit FTP proxy using IP address 10.31.101.100 and port 2121.

Example explicit FTP proxy network topology

In this example, explicit FTP proxy users must authenticate with a RADIUS server before getting access to the proxy. To apply authentication, the security policy that accepts explicit FTP proxy traffic includes an identity based policy that applies per session authentication to explicit FTP proxy users and includes a user group with the RADIUS server in it. The identity based policy also applies UTM virus scanning and DLP.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit FTP proxy and change the FTP port to 2121.
2. Enable the explicit FTP proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit FTP proxy.
4. Add a user identity security policy for the explicit FTP proxy.
5. Enable antivirus and DLP features for the identity-based policy.

Configuring the explicit FTP proxy - web-based manager

Use the following steps to configure the explicit FTP proxy from FortiGate web-based manager.

To enable and configure the explicit FTP proxy

1. Go to **Network > Explicit Proxy > Explicit FTP Proxy Options** and change the following settings:

Enable Explicit FTP Proxy	Select.
Listen on Interface	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
FTP Port	2121
Default Firewall Policy Action	Deny

2. Select **Apply**.

To enable the explicit FTP proxy on the Internal interface

1. Go to **Network > Interfaces**, edit the Internal interface and select **Enable Explicit FTP Proxy**.

To add a RADIUS server and user group for the explicit FTP proxy

1. Go to **User & Device > RADIUS Servers**.
2. Select **Create New** to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

3. Go to **User > User > User Groups** and select **Create New**.

Name	Explicit_proxy_user_group
Type	Firewall
Remote groups	RADIUS_1
Group Name	ANY

4. Select **OK**.

To add a security policy for the explicit FTP proxy

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Add a firewall address for the internal network:

Address Name	Internal_subnet
Type	Subnet
Subnet / IP Range	10.31.101.0
Interface	Any

3. Go to **Policy & Objects > Proxy Policy** and select **Create New**.
4. Configure the explicit FTP proxy security policy.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

5. Under **Configure Authentication Rules** select **Create New** to add an authentication rule:

Groups	Explicit_policy
Users	Leave blank
Schedule	always

6. Turn on **Antivirus** and **Web Filter** and select the **default** profiles for both.
7. Select the **default** proxy options profile.
8. Select **OK**.
9. Make sure **Enable IP Based Authentication** is not selected and **DefaultAuthentication Method** is set to **Basic**.
10. Select **OK**.

Configuring the explicit FTP proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable and configure the explicit FTP proxy

1. Enter the following command to enable the explicit FTP proxy and set the TCP port that proxy accepts FTP connections on to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
  set sec-default-action deny
end
```

To enable the explicit FTP proxy on the Internal interface

1. Enter the following command to enable the explicit FTP proxy on the internal interface.

```
config system interface
  edit internal
    set explicit-ftp-proxy enable
  end
```

To add a RADIUS server and user group for the explicit FTP proxy

1. Enter the following command to add a RADIUS server:

```
config user radius
edit RADIUS_1
set server 10.31.101.200
set secret RADIUS_server_secret
end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
edit Explicit_proxy_user_group
set group-type firewall
set member RADIUS_1
end
```

To add a security policy for the explicit FTP proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
edit Internal_subnet
set type iprange
set start-ip 10.31.101.1
set end-ip 10.31.101.255
end
```

2. Enter the following command to add the explicit FTP proxy security policy:

```
config firewall proxy-policy
edit 0
set proxy ftp
set dstintf wan1
set srcaddr Internal_subnet
set dstaddr all
set action accept
set identity-based enable
set ipbased disable
set active-auth-method basic
set groups <User group>
end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit FTP proxy configuration is working as expected. These steps use a command line FTP client.

To test the explicit web proxy configuration

1. From a system on the internal network start an FTP client and enter the following command to connect to the FTP proxy:

```
ftp 10.31.101.100
```

The explicit FTP proxy should respond with a message similar to the following:

```
Connected to 10.31.101.100.
220 Welcome to Floodgate FTP proxy
Name (10.31.101.100:user):
```

2. At the prompt enter a valid username and password for the RADIUS server followed by a user name for an FTP server on the Internet and the address of the FTP server. For example, if a valid username and password on the

RADIUS server is ex_name and ex_pass and you attempt to connect to an FTP server at ftp.example.com with user name s_name, enter the following at the prompt:

```
Name (10.31.101.100:user):ex_name:ex_pass:s_name@ftp.example.com
```

3. You should be prompted for the password for the account on the FTP server.
4. Enter the password and you should be able to connect to the FTP server.
5. Attempt to explore the FTP server file system and download or upload files.
6. To test UTM functionality, attempt to upload or download an ECAR test file. Or upload or download a text file containing text that would be matched by the DLP sensor.

For eicar test files, go to <http://eicar.org>.

Diagnose commands for WAN optimization

The following get and diagnose commands are available for troubleshooting WAN optimization, web cache, explicit proxy and WCCP.

get test {wad | wccpd} <test_level>

Display usage information about WAN optimization, explicit proxy, web cache, and WCCP applications. Use <test_level> to display different information.

```
get test wad <test_level>
get test wccpd <test_level>
```

Variable	Description
wad	Display information about WAN optimization, web caching, the explicit web proxy, and the explicit FTP proxy.
wccpd	Display information about the WCCP application.

Examples

Enter the following command to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 1
WAD manager process status: pid=113 n_workers=1 ndebug_workers=0
```

Enter the following command to display all test options:

```
get test wad

WAD process 82 test usage:
 1: display process status
 2: display total memory usage.
 99: restart all WAD processes
1000: List all WAD processes.
1001: display debug level name and values
1002: display status of WANOpt storages
1068: Enable debug for all WAD workers.
1069: Disable debug for all WAD workers.
2yxx: Set No. xx process of type y as diagnosis process.
 3: display all fix-sized advanced memory stats
 4: display all fix-sized advanced memory stats in details
500000..599999: cmem bucket stats (599999 for usage)
800..899: mem_diag commands (800 for help & usage)
800000..899999: mem_diag commands with 1 arg (800 for help & usage)
80000000..89999999: mem_diag commands with 2 args (800 for help & usage)
 60: show debug stats.
 61: discard all wad debug info that is currently pending
62xxx: set xxxM maximum output buffer size for WAD debug. 0, set back to default.
 68: Enable process debug
```

```

69: Disable process debug
98: gracefully stopping WAD process
9xx: Set xx workers(0: default based on user configuration.)

```

diagnose wad

Display diagnostic information about the WAN optimization daemon (wad).

```

diagnose wad console-log {disable | enable}
diagnose wad debug-url {disable | enable}
diagnose wad filter {clear | dport | dst | list | negate | protocol | sport | src | vd}
diagnose wad history {clear | list}
diagnose wad session {clear | list}
diagnose wad stats {cache | cifs | clear | crypto | ftp | http | list | mapi | mem |
    scan | scripts | summary | tcp | tunnel}
diagnose wad user {clear | list}
diagnose wad tunnel {clear | list}1
diagnose wad webcache {clear | list} {10min | hour | day | 30days}

```

Variable	Description
console-log	Enable or disable displaying WAN optimization log messages on the CLI console.
filter	Set a filter for listing WAN optimization daemon sessions or tunnels.
	clear reset or clear the current log filter settings.
	dport enter the destination port range to filter by.
	dst enter the destination address range to filter by.
history	list display the current log filter settings
	Display statistics for one or more WAN optimization protocols for a specified period of time (the last 10 minutes, hour, day or 30 days).
session	Display diagnostics for WAN optimization sessions or clear active sessions.
stats	Display statistics for various parts of WAN optimization such as cache statistics, CIFS statistics, MAPI statistics, HTTP statistics, tunnel statistics etc. You can also clear WAN optimization statistics and display a summary.
tunnel	Display diagnostic information for one or all active WAN optimization tunnels. Clear all active tunnels. Clear all active tunnels.
webcache	Display web cache activity for the specified time period.

Example diagnose wad tunnel list

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=100 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=99 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=348 bytes_out=384

Tunnel: id=98 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=98 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=348 bytes_out=384

Tunnel: id=39 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=39 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1068 bytes_out=1104

Tunnel: id=7 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=7 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=8 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=8 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=5 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=5 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=4 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=4 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=1 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=1 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=2 type=manual
```

```

vd=0 shared=no uses=0 state=3
peer name=Web_servers id=2 ip=172.20.120.141
SSL-secured-tunnel=no auth-grp=
bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0

```

Example diagnose wad webcache list

This following command displays the web caching stats for the last 10 minutes of activity. The information displayed is divided into 20 slots and each slot contains stats for 30 seconds:

20 * 30 seconds = 600 seconds = 10 minutes

```

diagnose wad webcache list 10min
web cache history vd=0 period=last 10min

```

The first 20 slots are for HTTP requests in the last 10 minutes. Each slot of stats has four numbers, which is the total number of HTTP requests, the number of cacheable HTTP requests, the number of HTTP requests that are processed by the web cache (hits), and the number of HTTP requests that are processed without checking the web cache (bypass). There are many reasons that a HTTP request may bypass web cache.

total	cacheable	hits	bypass
-----	-----	-----	-----
36	10	3	1
128	92	1	10
168	97	2	3
79	56	0	3
106	64	5	3
180	118	6	11
88	53	7	3
80	43	4	4
107	44	9	2
84	12	0	2
228	139	52	10
32	2	0	5
191	88	13	7
135	25	40	3
48	10	0	8
193	13	7	7
67	31	1	2
109	35	24	6
117	36	10	5
22	0	0	4

The following slots are for video requests in the last 10 minutes. Each slot has two numbers for each 30 seconds: total number of video requests, and the number of video requests that are processing using cached data.

[illegible]

The following 20 slots are for traffic details in last 10 minutes. Each slot has four numbers for 30 seconds each.

--- LAN ---		--- WAN ---	
bytes_in	bytes_out	bytes_in	bytes_out
34360	150261	141086	32347

diagnose wad csvc

The `diagnose wad csvc` command refers to the `cache-service`. The next options to the command are listed in the table. Some will have there own sub options for refining the output or results.

Option	Description
<code>memory</code>	Cache service memory diagnostics

Option	Description
webcache	Webcache diagnostics
bytecache	Bytecache diagnostics
memcache	Memcache diagnostics
restart	Restart cache service

diagnose wad worker

The `diagnose wad worker` command has some settings that show useful WAD stats for one or all workers. The next options to the command are listed in the table. Some will have their own sub options for refining the output or results.

Option	Description
memory	WAD worker memory diagnostics.
tcp	TCP statistics.
ssl	SSL statistics.
tunnel	Tunnel statistics.
webcache	Webcache diagnostics.
bytecache	Bytecache diagnostics.
memcache	Memcache diagnostics.
restart	Restart workers.

diagnose wacs

Display diagnostic information for the web cache database daemon (wacs).

```
diagnose wacs clear
diagnose wacs reents
diagnose wacs restart
diagnose wacs stats
```

Variable	Description
<code>clear</code>	Remove all entries from the web cache database.
<code>reents</code>	Display recent web cache database activity.

Variable	Description
restart	Restart the web cache daemon and reset statistics.
stats	Display web cache statistics.

diagnose wadbd

Display diagnostic information for the WAN optimization database daemon (wadbd).

```
diagnose wadbd {check | clear | reents | restart | stats}
```

Variable	Description
check	Check WAN optimization database integrity.
clear	Remove all entries from the WAN optimization database.
reents	Display recent WAN optimization database activity.
restart	Restart the WAN optimization daemon and reset statistics.
stats	Display WAN optimization statistics.

diagnose debug application {wad | wccpd} [<debug_level>]

View or set the debug level for displaying WAN optimization and web cache-related daemon debug messages. Include a <debug_level> to change the debug level. Leave the <debug_level> out to display the current debug level. Default debug level is 0.

```
diagnose debug application wad [<debug_level>]
diagnose debug application wccpd [<debug_level>]
```

Variable	Description
wad	Set the debug level for the WAN optimization daemon.
wccpd	Set the debug level for the WCCP daemon.

diagnose test application wad 2200

The debug level 2200 switches the debug to explicit proxy mode. You have to enter this debug level first. After that you have to type the command again with a different debug level to check the different explicit proxy statistics. To list what each debug level shows, follow these steps in any FortiGate device:

1. Enable explicit proxy globally and in one interface, to start the wad process. If the wad process is *not* running, you *cannot* list the options.
2. Once the wad process starts, type:

```
diagnose test application wad 2200
diagnose test application wad //// Do not type any debug level value to list all the options.
```

This is the output you will get:

```
# diagnose test application wad 2200
Set diagnosis process: type=wanopt index=0 pid=114
# diagnose test application wad
WAD process 114 test usage:
1: display process status
2: display total memory usage
99: restart all WAD processes
1000: List all WAD processes
1001: display debug level name and values
1002: display status of WANOpt storages
1068: Enable debug for all WAD workers
1069: Disable debug for all WAD workers
2yxx: Set No. xx process of type y as diagnosis process
3: display all fix-sized advanced memory stats
4: display all fix-sized advanced memory stats in details
500000..599999: cmem bucket stats (599999 for usage)
800..899: mem_diag commands (800 for help & usage)
800000..899999: mem_diag commands with 1 arg (800 for help & usage)
80000000..89999999: mem_diag commands with 2 args (800 for help & usage)
60: show debug stats
61: discard all wad debug info that is currently pending
62xxx: set xxxM maximum output buffer size for WAD debug (0: set back to default)
68: Enable process debug
69: Disable process debug
98: gracefully stopping WAD process
20: display all listeners
21: display TCP port info
22: display SSL stats
23: flush SSL stats
24: display SSL mem stats
70: display av memory usage
71xxxx: set xxxMiB maximum AV memory (0: set back to default)
72: toggle av memory protection
73: toggle AV conserve mode (for debug purpose)
90: set to test disk failure
91: unset to test disk failure
92: trigger a disk failure event
100: display explicit proxy settings
101: display firewall policies
102: display security profile mapping for regular firewall policy
103: display Web proxy forwarding server and group
104: display DNS stats
105: display proxy redirection scan stats
106: list all used fqdns
107: list all firewall address
110: display current web proxy users
111: flush current web proxy users
112: display current web proxy user summary
113: display WAD fsso state
114: display HTTP digest stats
115: display URL patterns list of cache exemption or forward server
116: toggle dumping URL when daemon crashes
120: display Web Cache stats
```

```
121: flush Web Cache stats
122: flush idle Web cache objects
123: display web cache cache sessions
130: display ftpproxy stats
131: clear ftpproxy stats
132: list all current ftpproxy sessions
133: display all caughted webfilter profiles
200: display WANopt profiles
201: display all peers
202: display video cache rules (patterns)
203: display all ssl servers
210: toggle disk-based byte-cache
211: toggle memory-based byte-cache
212: toggle cifs read-ahead
221: display tunnel protocol stats
222: flush tunnel protocol stats
223: display http protocol stats
224: flush http protocol stats
225: display cifs protocol stats
226: flush cifs protocol stats
227: display ftp protocol stats
228: flush ftp protocol stats
229: display mapi protocol stats
230: flush mapi protocol stats
231: display tcp protocol stats
232: flush tcp protocol stats
233: display all protocols stats
234: flush all protocols stats
240: display WAD tunnel stats
241: display tunnel compressor state
242: flush tunnel compressor stats
243: display Byte Cache DB state
244: flush Byte Cache DB stats
245: display Web Cache DB state
246: flush Web Cache DB stats
247: display cache state
248: flush cache stats
249: display memory cache state
250: flush memory cache stats
261yxxx: set xxx concurrent Web Cache session for object storage y
262yxxx: set xxxK(32K, 64K,...) unconfirmed write/read size per Web Cache object for
        object storage y
263yxxxx: set xxxK maximum ouput buffer size for object storage y
264yxx: set lookup lowmark (only if more to define busy status) to be xx for object
        storage y
265yxxx: set xxxK maximum ouput buffer size for byte storage y
266yxxx: set number of buffered add requests to be xxx for byte storage y
267yxxxx: set number of buffered query requests to be xxxx for byte storage y
268yxxxxx: set number of concurrent query requests to be xxxxx for byte storage y
```

Chapter 7 - FortiView

- [Overview on page 924](#) outlines the role FortiView plays in FortiOS and its overall layout. This section also identifies which FortiGate platforms support the full FortiView features.
- [FortiView consoles on page 935](#) describes the various FortiView consoles available in FortiOS, including example scenarios, in most cases.
- [Reference on page 946](#) explains reference information for the various consoles in FortiView, and describes the assortment of filtering options, drilldown options, and columns available.
- [Troubleshooting FortiView on page 958](#) offers solutions to common technical issues experienced by FortiGate users regarding FortiView.

What's new in FortiOS 6.0

The following list contains new FortiView features added in FortiOS 6.0 and subsequent versions.

What's New in FortiOS 6.0

These features first appeared in FortiOS 6.0.

Increased visibility of interactivity in FortiView

FortiOS 6.0 has improved visual feedback on mouse-over of FortiView charts, to increase visibility of interactive elements. Cursors have also been updated to display possible interactions.

Automatic synchronization of log display location

In previous versions, log display location could differ between Log & Report and FortiView, which could result in empty log screens if the two were not synchronized. Now, both log viewers automatically pick the best available log device. A different log device can be manually selected.

As a result, the associated CLI command `log gui-display location` has been removed.

Improved log display consistency at high load

Previous versions could display inconsistent log data when using Drill Down charts and when navigating between different log tables (in both **Log & Report** and **FortiView**). The maximum number of records now varies based on length that logs are kept, relative to device model size. Record numbers are configurable in `config report setting`.

Log database queries used to collect **Top Sources** and **Top Destinations** data are significantly more efficient due to improved indexing speed.

Improved FortiView > Cloud Application

Previously, the **Cloud Application** view required that you enable deep inspection on a firewall policy to display any results. In 6.0, when applications are detected with the "Cloud" behavior category, it will be recorded and displayed in **Cloud Application** view, even when deep inspection is disabled.

New Destination > Owner views and FortiView features

A new Owner category has been added to **FortiView > Destination** visualizations. Used for tracking multiple devices across remote networked clients based on FortiClient data, the Owner view also appears in Topology pages and drilldown charts for Realtime, Historical Disk, and FortiAnalyzer logging data.

Retrieve FortiView data from FortiCloud

In 6.0, FortiView will retrieve data from FortiCloud for a wider range of pages, now supporting every page that is also supported by FortiAnalyzer.

Supported pages are: **Sources, Destinations, Applications, Cloud Applications, Web Sites, Threats, WiFi Clients, System Events, VPN, Endpoint Vulnerability, Policies, Interfaces, All Sessions, Physical Topology, Logical Topology, and FortiSandbox.**

Various GUI fixes

Various other small interface fixes were implemented in 6.0:

- Bubble chart color now matches threat level, if one is set.
- New icons added for various device types.
- Colors of icons, charts, and other visualizations have been updated for clarity and contrast.

Purpose

FortiView is a comprehensive monitoring system for your network that integrates real-time and historical data into a single view on your FortiGate. It can log and monitor threats to networks, filter data on multiple levels, keep track of administrative activity, and more.

FortiView allows you to use multiple filters within the consoles, enabling you to narrow your view to a specific time (up to 24 hours in the past), by user ID or local IP address, by application, and many more. For more on FortiView's filtering options, see [Filtering options on page 947](#)

FortiView can be used to investigate traffic activity, such as user uploads/downloads or videos watched on YouTube, on a network-wide, user group, and individual-user level, with information relayed in both text and visual format. FortiView makes it easy to get an actionable picture of your network's internet activity.

The degree to which information can be logged will depend on which FortiGate unit you have. For more information, see [Enabling FortiView on page 925](#).

Overview

This section provides an overview of FortiView, its interface, and options, including the following:

Enabling FortiView

By default, FortiView is enabled on FortiGate running FortiOS firmware version 5.2 and above. You will find the FortiView consoles in the main menu. However, certain options will not appear unless the FortiGate has **Disk Logging** enabled.

Only certain FortiGate models support Disk Logging. A complete list of FortiGate platforms that support Disk Logging is provided in the matrix below.

To enable Disk Logging

1. Go to **Log & Report > Log Settings** and select the checkbox next to **Disk**.
2. **Apply** the change.

To enable Disk Logging - CLI

```
config log disk setting
    set status enable
end
```

FortiView feature support - platform matrix

Note that the following table identifies three separate aspects of FortiView in FortiOS, which are explained in greater detail below:

- [Basic feature support](#)
- [Historical data](#)
- [Disk logging](#)

Platform	Basic Feature Support	Disk Logging	Historical Data *
FG/FWF-30D/E Series	✓		
FG/FWF-50E	✓		
FG/FWF-51E	✓	✓	1 hour
FG-52E	✓	✓	1 hour

FG-3980E	✓	✓	7 days
FG-5001D	✓	✓	7 days

✓ = Default support.

* Refer to section on Historical Data below.

Basic feature support

FortiView's consoles give insight into your user's traffic, not merely showing which users are creating the most traffic, but what sort of traffic it is, when the traffic occurs, and what kind of threat the traffic may pose to the network.

FortiView basic feature support consists of the following consoles:

- [Sources](#)
- [Destinations](#)
- [Interfaces](#)
- [Policies](#)
- [All Sessions](#)
- [Applications](#)

The complete array of features in FortiView requires disk logging enabled (see below). It includes those consoles listed above as well as the following:

- [WiFi Clients](#)
- [Cloud Applications](#)
- [Web Sites](#)

- [Threats](#)
- [VPN](#)

Historical data

Not all consoles have the same available historical data options, depending on whether or not your traffic is locally stored.

Below is a table showing which features are available for units using local storage, including the historical data options.

Only FortiGate models 100D and above support the 24 hour historical data.

Features	With Local Storage				Without Local Storage			
	Now	5 min	1 hr	24 hr *	Now	5 min	1 hr	24 hr
Sources	✓	✓	✓	✓	✓			
Destinations	✓	✓	✓	✓	✓			
Interfaces	✓	✓	✓	✓				
Policies	✓	✓	✓	✓				
All Sessions	✓	✓	✓	✓	✓			
Applications	✓	✓	✓	✓	✓			
WiFi Clients		✓	✓	✓				
Cloud Applications	✓	✓	✓	✓	✓			
Web Sites	✓	✓	✓	✓				
Threats		✓	✓	✓				
Threat Map	✓				✓			
FortiSandbox		✓	✓	✓				
System Events		✓	✓	✓				
VPN		✓	✓	✓				

* Not available for desktop models with SSD.

7-day time display

As mentioned previously, certain models support 7-day time display. These models are listed below:

- FortiGate 1000D
- FortiGate 1500D
- FortiGate 3700DX
- FortiGate 3700D

The option for 7-day time display, however, can only be configured in the CLI using the following command:

```
config log setting
    set fortiview-weekly-data {enable|disable}
end
```

Disk logging

Only certain FortiGate models support Disk Logging (see above).

To enable Disk Logging, go to **Log & Report > Log Settings**, and select the checkbox next to **Disk** and apply the change. Some devices will require disk logging to be enabled in the CLI, using the following command:

```
config log disk setting
    set status enable
end
```

Configuration dependencies

Most FortiView consoles require the user to enable several features to produce data. The following table summarizes the dependencies:

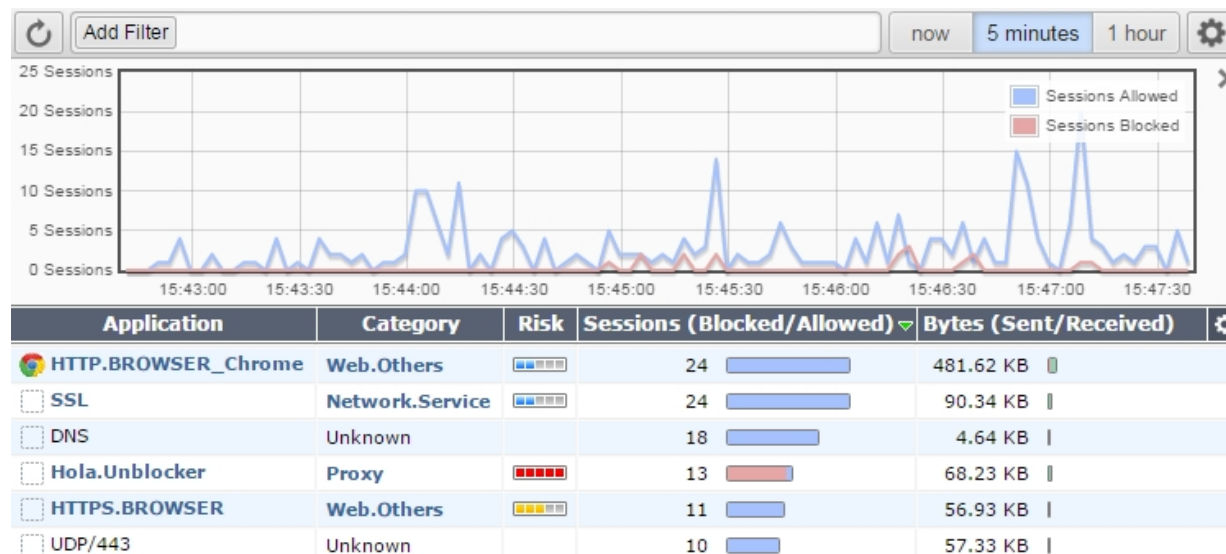

Feature	Dependencies (Realtime)	Dependencies (Historical)
Sources	None, always supported	Traffic logging enabled in policy
Destinations	None, always supported	Traffic logging enabled in policy
Interfaces	None, always supported	Disk logging enabled Traffic logging enabled in policy
Policies	None, always supported	Disk logging enabled Traffic logging enabled in policy
All Sessions	None, always supported	Traffic logging enabled in policy
Applications	None, always supported	Disk logging enabled Traffic logging enabled in policy Application control enabled in policy

Feature	Dependencies (Realtime)	Dependencies (Historical)
WiFi Clients	SSID must be in Tunnel mode	Disk logging enabled Traffic logging enabled in policy SSID must be in Tunnel mode
Cloud Applications	Not supported	Disk logging enabled Application control enabled in policy SSL "deep inspection" enabled in policy Deep application inspection enabled in application sensor Extended UTM log enabled in application sensor
Web Sites	Disk logging enabled Web Filter enabled in policy "web-url-log" option enabled in Web Filter profile	Disk logging enabled Web Filter enabled in policy "web-url-log" option enabled in Web Filter profile
Threats	Not supported	Disk logging enabled Traffic logging enabled in policy Threat weight detection enabled
Threat Map	None, always supported	Disk logging enabled Traffic logging enabled in policy Threat weight detection enabled
FortiSandbox	Not supported	Disk logging enabled Traffic logging enabled in policy
System Events	Not supported	Disk logging enabled
VPN	Not supported	Disk logging enabled Traffic logging enabled in policy

FortiView interface

FortiView lets you access information about the traffic activity on your FortiGate, visually and textually. FortiView is broken up into several consoles, each of which features a top menu bar and a graph window, as seen in the following image:

FortiView Application console sorted by Sessions (Blocked/Allowed)

The top menu bar features:

- a **Refresh** button, which updates the data displayed,
- a **Filter** button, for filtering the data by category,
- a **Settings** button (containing additional viewing settings and a link to the Threat Weight menu).
- a drop-down menu of different views:
 - **Time Display** (options: now, 5 minutes, 1 hour, or 24 hours),
 - **Table View**
 - **Timeline View**
 - **Bubble Chart**¹
 - **Country Map**

¹ For information on the Bubble Chart, refer to [Bubble chart visualization on page 932](#).

Certain views are only available in specific consoles.

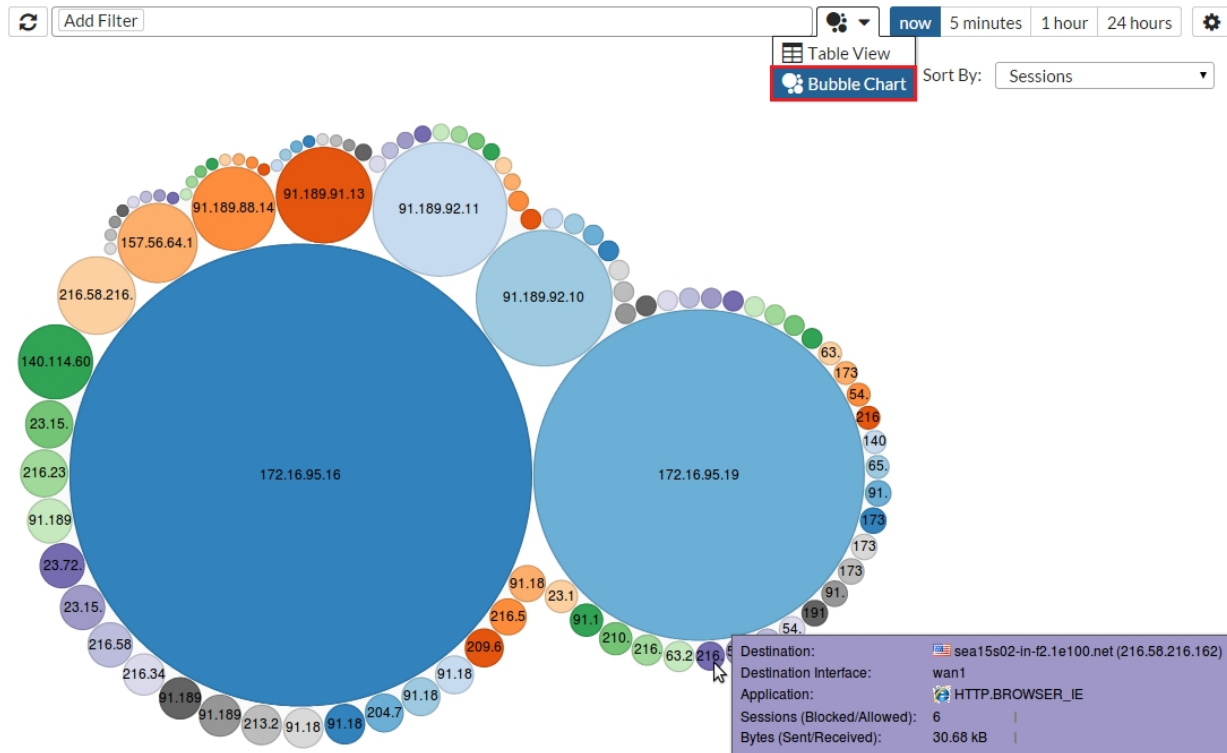

The FortiView graph

The graph window can be hidden using the **X** in the top right corner, and re-added by selecting **Show Graph**. To zoom in on a particular section of the graph, click and drag from one end of the desired section to the other. This will appear in the **Time Display** options as a **Custom** selection. The minimum selection size is 60 seconds.

Only FortiGate models 100D and above support the 24 hour historical data.

Bubble chart visualization

Notes about the Bubble chart:

- It is possible to sort on the Bubble chart using the **Sort By:** dropdown menu.
- The size of each bubble represents the related amount of data.
- Place your cursor over a bubble to display a tool-tip with detailed info on that item.
- You can click on a bubble to drilldown into greater (filtered) detail.

Links created between FortiView and View/Create Policy

The **Policy** column in FortiView consoles and the Log Viewer pages includes a link, which navigates to the IPv4 or IPv6 policy list and highlights the policy.

Right-clicking on a row in FortiView or the Log Viewer has menu items for **Block Source**, **Block Destination** and **Quarantine Source** where appropriate columns are available to determine these values. When multiple rows are selected, the user will be prompted to create a named **Address Group** to contain the new addresses.

When the user clicks **Block Source** or **Block Destination** they are taken to a policy creation page with enough information filled in to create a policy blocking the requested IP traffic.

The policy page will feature an informational message block at the top describing the actions that will be taken. Once the user submits the form, the requisite addresses, groups and policy will be created at once.

If the user clicks on **Quarantine User** then they will be prompted for a duration. They may also check a box for a **Permanent Ban**. The user can manage quarantined users under **Monitor > Quarantine Monitor**.

Visualization support for the Admin Logins page

A useful chart is generated for Admin login events under **FortiView > Admin Logins**. You can view the information in either **Table View** or **Timeline View** (shown below). In Timeline View, each line represents an administrator, with individual sessions indicated per administrator line. When you hover over a particular timeline, detailed information appears in a tooltip.

Realtime visualization

To enable realtime visualization:

1. Click on the **Settings** icon next to the upper right-hand corner and select **Auto update realtime visualizations**. An option is displayed to set the **Interval (seconds)**. The maximum value is 300.
2. Enter a desired **Interval** and click **Apply**.

Accelerated sessions

When viewing sessions in the [All Sessions](#) console, information pertaining to NP4/ NP6 acceleration is now reflected via an appropriate icon in the table. The tooltip for the icon includes the NP chip type and its total number of accelerated sessions.

Filtering on accelerated sessions

You can filter the console on 'FortiASIC' ('Accelerated' versus 'Not Accelerated') sessions.

WHOIS Lookup anchor for public IPv4 addresses

A Reverse IP lookup is possible using the WHOIS lookup icon available when you mouse over a public IP address in a FortiView log. If you left-click on the lookup icon, a new tab is opened in your browser for www.networksolutions.com, and a lookup is performed on the selected IP address (this option persists after drilling down one level in FortiView).

FortiView consoles

This section describes the following log filter consoles available in FortiView:

- [Sources on page 936](#) displays detailed information on the sources of traffic passing through the FortiGate, and the section covers how you can investigate an unusual spike in traffic to determine which user is responsible.
- [Destinations on page 936](#) displays detailed information on user destination-accessing through the use of drill down functionality.
- [Applications on page 937](#) displays Applications used on the network that have been recognized by Application Control, and this section shows how you can view what sort of applications individual employees are using.
- [Cloud Applications on page 937](#) displays Web/Cloud Applications used on the network, and this section shows how you can drill down to access detailed data on cloud application usage, e.g. YouTube.
- [Web Sites on page 938](#) displays websites visited as part of network traffic that have been recognized by Web Filtering, and this section shows how you can investigate instances of proxy avoidance, which is the act of circumventing blocks using proxies.
- [Threats on page 939](#) monitors threats to the network, both in terms of their Threat Score and Threat Level.
- [WiFi Clients on page 940](#) displays a list of all the devices connected to the WLAN.
- ["Traffic Shaping" on page 940](#) displays a list of existing Traffic Shapers, detailing their bandwidth use and which traffic is being shaped by each shaper.
- [System Events on page 940](#) displays security events detected by FortiOS, providing a name and description for the events, an assessment of the event's severity level, and the number of instances the events were detected.
- [VPN on page 941](#) displays how users can access information on any VPNs associated with their FortiGate.
- ["Endpoint Vulnerability" on page 942](#) displays a list of Vulnerability events detected by the FortiGate on networked devices, along with links to further vulnerability information and databases.
- [Threat Map on page 942](#) provides a geographical display of threats, in realtime, from international sources as they arrive at your FortiGate.
- [Policies on page 943](#) displays what policies are in affect on your network, what their source and destination interfaces are, how many sessions are in each policy, and what sort of traffic is occurring.
- [Interfaces on page 944](#) displays the number of interfaces connected to your network, how many sessions there are in each interface, and what sort of traffic is occurring.
- [FortiSandbox on page 944](#) displays FortiSandbox activity. FortiSandbox detects and analyzes advanced attacks designed to bypass traditional security defenses, and has a wide array of features that allow it to prevent future attacks from occurring again.
- [All Sessions on page 945](#) displays complete information on all FortiGate sessions, with the ability to filter sessions by port number and application type.

Sources

The **Sources** console provides information about the sources of traffic on your FortiGate unit.

This console can be filtered by Country, Destination Interface, Policy, Result, Source, and Source Interface. For more on filters, see [Filtering options](#).

Specific devices and time periods can be selected and drilled down for deep inspection.

Scenario: Investigating a spike in traffic

A system administrator notices a spike in traffic and wants to investigate it. From the **Sources** window, they can determine which user is responsible for the spike by following these steps:

1. Go to **FortiView > Sources**.
2. In the graph display, click and drag across the peak that represents the spike in traffic.
3. Sort the sources by bandwidth use by selecting the **Bytes (Sent/Received)** header.
4. Drill down into whichever source is associated with the highest amount of bandwidth use by double-clicking it. From this screen, you have an overview of that source's traffic activity.
5. Again, in either the **Applications** or **Destinations** view, select the **Bytes (Sent/Received)** header to sort by bandwidth use.
6. Double-click the top entry to drill down to the final inspection level, from which you can access further details on the application or destination, and/or apply a filter to prohibit or limit access.

Only FortiGate models 100D and above support the 24 hour historical data.

Destinations

The **Destinations** console provides information about the destination IP addresses of traffic on your FortiGate unit, as well as the application used. You can drill down the displayed information, and also select the device and time period, and apply search filters.

This console can be filtered by Country, Destination Interface, Destination IP, Policy, Result, and Source Interface. For more on filters, see [Filtering options](#).

Scenario: Monitoring destination data

The Destinations console can be used to access detailed information on user destination-accessing through the use of the console's drilldown functionality. In this scenario, the console is used to find out more about a particular user's Facebook usage patterns over a 24-hour period:

1. Go to **FortiView > Destinations**.
2. Select **1 hour** from the Time Display options at the top right corner of the console.
3. The easiest way to locate most destinations is to scan the Applications column for the name of the application. Once the session containing Facebook has been located, double-click it to access the Destination summary window.

4. Locate Facebook in the Applications column and double-click it to view the Facebook drilldown page. From here, detailed information regarding the user's Facebook session can be accessed.

Only FortiGate models 100D and above support the 24 hour historical data.

Applications

The **Applications** console provides information about the applications being used on your network.

This console can be filtered by Application, Country, Destination Interface, Policy, Result, and Source Interface. For more on filters, see [Filtering options](#).

Specific devices and time periods can be selected and drilled down for deep inspection.

In order for information to appear in the **Applications** console, Application Control must be enabled in a policy.

Scenario: Viewing application usage

A manager is interested in the office internet habits of their employees:

1. Go to **FortiView > Applications**, to view the list of applications accessed by the users on your network. Use the time-frame options to view what applications were used in those time periods (from now, 5 minutes, 1 hour, or 24 hours).
2. From **Sessions (Blocked/Allowed)** and **Bytes (Sent/Received)**, you can see how much traffic has been generated. Click these columns to show the traffic in descending order.
3. You notice that a social media application has created the most traffic of all the applications, and so it's at the top of the list. Drill down into the application by double-clicking or right-clicking and select **Drill Down to Details**.
4. You are directed to a summary page of the social media application. From here, you can see which specific user has made the most use of the application.

Only FortiGate models 100D and above support the 24 hour historical data.

Cloud Applications

The **Cloud Applications** console provides information about the cloud applications being used on your network. This includes information such as:

- The names of videos viewed on YouTube (visible by hovering the cursor over the session entry)
- Files uploaded and downloaded from cloud hosting services such as Dropbox
- Account names used for cloud services

Two different views are available for the Cloud Applications: **Applications** and **Users** (located in the top menu bar next to the time periods). **Applications** shows a list of the programs being used. **Users** shows information on the individual users of the cloud applications, including the username, if the FortiGate was able to view the login event.

This console can be filtered by Cloud Application and Result. For more on filters, see [Filtering options](#).

In order for information to appear in the **Cloud Applications** console, an application control profile (that has Deep Inspection of Cloud Applications turned on) must be enabled in a policy, and SSL Inspection must use `deep-inspection`.

Scenario: Viewing cloud application usage data

From the Cloud Applications console, users can drill down to access detailed data on cloud application usage data. In this scenario, the console is used to determine the network's most frequent user of YouTube over a 24-hour period, and find out more about their usage patterns.

1. Go to **FortiView > Cloud Applications**.
2. Select **Applications** view from the top menu bar if it is not already selected.
3. Select **24 Hours** from the Time Display options.
4. Find **YouTube** under the Application column and double-click it (or right-click and select **Drill down for details...**). This will open the YouTube stats window.
5. To determine the user who has accessed YouTube the most frequently, sort the column entries by **Sessions** by selecting the column header of the same name.
6. Double-click (or right-click and select **Drill down for details...**) the top-bandwidth YouTube user to view detailed stats, including the names of videos watched by the user and the date and time each video was accessed.

Only FortiGate models 100D and above support the 24 hour historical data.

Web Sites

The **Web Sites** console lists the top allowed and top blocked web sites. You can view information by domain or by FortiGuard categories by using the options in the top right corner. Each FortiGuard category can be selected in order to see a description of the category and several example sites, with content loaded from FortiGuard on demand.

This console can be filtered by Domain and Result. For more on filters, see [Filtering options](#).

In order for information to appear in the **Web Sites** console, web filtering must be enabled in a policy, with FortiGate Categories enabled.

Scenario: Investigating an instance of Proxy Avoidance

In this scenario, the Categories view will be used to investigate an instance of Proxy Avoidance, one of the Categories recognized by FortiOS. Proxy Avoidance denotes the use of a proxy site in order to access data that

might otherwise be blocked by the server.

1. Go to **FortiView > Web Sites** to open the Web Sites console.
2. Select **Categories** from the top bar menu to enter Categories view.
3. Scan the **Categories** column and locate the instance of Proxy Avoidance, then double-click it to enter its drilldown screen.

Only FortiGate models 100D and above support the 24 hour historical data.

Threats

The **Threats** console lists the top users involved in incidents, as well as information on the top threats to your network.

The following incidents are considered threats:

- Risk applications detected by application control
- Intrusion incidents detected by IPS
- Malicious web sites detected by web filtering
- Malware/botnets detected by antivirus

This console can be filtered by Country, Destination Interface, Policy, Result, Security Action, Source Interface, Threat, and Threat Type. For more on filters, see [Filtering options](#).

In order for information to appear in the **Threats** console, Threat Weight Tracking must be enabled.

Scenario: Monitoring Threats to the Network

Some users have high Threat Scores. The Threats console can be used to view all threats and discover why such high scores are being shown:

1. Go to **FortiView > Threats**. In the graph display, click and drag across the peak that represents the spike in threat score.
2. Sort the threats by score or level by selecting the **Threat Score (Blocked/Allowed)** or the **Threat Level** headers respectively.
3. You see that a specific threat's Threat Level is at Critical. Drill down into the threat by double-clicking or right-clicking and select **Drill down to details**.
4. From this summary page, you can view the source IPs and the number of sessions that came from this threat. Double-click on one of them.
5. The following page shows a variety of statistics, including **Reference**. The URL next to it will link you to a FortiGuard page where it will display the description, affected products, and recommended actions, if you are not familiar with the particular threat.

Only FortiGate models 100D and above support the 24 hour historical data.

WiFi Clients

The **WiFi Clients** console shows a list of all the devices connected to the WLAN. The type of device, source, number of sources blocked and allowed, and bytes sent and received are displayed. The source's Service Set Identifier (SSID) is also displayed in the **Source SSID** column. An SSID is a case sensitive, 32 character alphanumerical identifier that acts as a password when a mobile device tries to connect to the WLAN.

This console can be filtered by AP, Device Type, Result, Source Device, Source IP, Source SSID, and User. For more on filters, see [Filtering options](#).

Scenario: Determining the threat risk of an individual WiFi client

In this scenario, the administrator will use the WiFi Clients FortiView console to determine the risk levels associated with an individual WiFi client, and then drilldown into that client to determine where the risk originates and who might be the offending user/IP.

1. Go to **FortiView > WiFi Clients** and view the device list table.
2. Double-click on a device to filter on that source.
3. Under the **Risk** column, identify the items that present the greatest risk (using the **Applications**, **Destinations**, **Threats**, and/or **Sessions** tabs, for example).
4. Right-click these items for further action.

Traffic Shaping

The **Traffic Shaping** console provides information about FortiGate Traffic Shapers that are currently in effect. This console can be filtered by Traffic Shaper Name. For more on filters, see [Filtering options](#).

A number of columns available in FortiView are only available in Traffic Shaping. For example, the **Shaper** column displays the name of the Shaper, which can be used to monitor the traffic being shaped by Bytes Sent, Received, and Dropped, so that bandwidth patterns and Shaper effectiveness can be analyzed.

Only FortiGate models 100D and above support the 24 hour historical data.

System Events

The **System Events** console lists security events detected by FortiOS, providing a name and description for the events, an assessment of the event's severity level (**Alert**, **Critical**, **Emergency**, **Error**, or **Warning**), and the number of instances the events were detected.

Two other FortiView pages from 5.4 have been wrapped into the **System Events** page as of 5.6: **Admin Logins**, and **Failed Authentication**.

This console can be filtered by Event Name, Result, and Severity. For more on filters, see [Filtering options on page 947](#).

Scenario: Investigate network security events

System Events can be used in conjunction with All Sessions to see what network security events took place, and specifically see what action was taken upon their detection:

1. Go to **FortiView > System Events** to see what and how many network events have taken place, as well as how severe they are in terms of the threat they pose to the network.
2. You see that a particular event has warranted a severe rating, and has allowed traffic to bypass the firewall. Note when the event took place, and go to **FortiView > All Sessions**, to see more information pertaining to the security event.
3. From this console, you can determine the system event's source, how much traffic was sent and received, and the security action taken in response to this security event. These actions differ, depending upon the severity of the security event. See the entry for **Security Action** in [Columns displayed on page 950](#).

Only FortiGate models 100D and above support the 24 hour historical data.

VPN

From the **VPN** console, users can access information on any VPNs associated with their FortiGate. From the initial window, a list of all the associated VPNs is provided, along with general information, such as number of user connections and VPN type. By double-clicking on an individual VPN (or right-clicking and selecting **Drill down for details...**), users can access more specific data on that VPN.

Logs in the VPN console can be sorted by number of connections, last connection time, or data sent/received by selecting the column headers.

This console can be filtered by Result, User Name, and VPN Type. For more on filters, see [Filtering options on page 947](#).

Certain dashboard options will not appear unless your FortiGate has Disk Logging enabled.

Furthermore, only certain FortiGate models support Disk Logging — refer to the [FortiView feature support - platform matrix on page 925](#) for more information.

To enable Disk Logging, go to **Log & Report > Log Settings**, and select the checkbox next to **Disk** and apply the change.

Scenario: Investigating VPN user activity

The VPN console can be used to access detailed data on VPN-user activity via the use of the drill down windows. In this scenario, the administrator looks into the usage patterns of the IPsec user who has most frequently connected to the network.

1. Go to **FortiView > VPN** to view the VPN console.
2. Select the **Connections** column header to sort the entries by number of connections to the network.

3. Locate the top user whose VPN Type is **ipsec** and double-click the entry to enter that user's drill down screen.
4. To get the most representative data possible, sort the entries by bandwidth use by selecting the **Bytes (Sent/Received)** column header. Double-click the top entry to enter the drill down window for that connection instance.

From this screen, the administrator can find out more about the specific session, including the date/time of access, the XAuth (Extensible Authentication) User ID, the session's Tunnel ID, and more.

Only FortiGate models 100D and above support the 24 hour historical data.

Endpoint Vulnerability

The **Endpoint Vulnerability** console lists the top devices and vulnerabilities detected, organized either by frequency or risk level.

This console can be filtered by Vulnerability Name, Severity, Vulnerability Category, CVE-ID, or Host Count. For more on filters, see [Filtering options](#).

The Vulnerabilities detected by the FortiGate use definitions created by FortiGuard, and every vulnerability in FortiView contains a link to the respective FortiGuard Labs documentation page (under the '**Vulnerability ID**' column) and the Common Vulnerabilities and Exposures documentation page (under the '**CVE-ID**' column.)

Scenario: Monitoring Vulnerabilities on the Network

When a vulnerability appears in log data, you can use the FortiView page to see more information about it. The Endpoint Vulnerability console can be used to view and track all historical vulnerabilities:

1. Go to **FortiView > Endpoint Vulnerability**. In the upper right, select **Vulnerability**.
2. Sort the threats by frequency by selecting the **Host Count** header.
3. You see that a frequent vulnerability's Severity is at Critical. Drill down into the threat by double-clicking or right-clicking and select **Drill down to details**.
4. From this summary page, you can view the source IPs and devices on which this vulnerability was detected, and also the **Scan Time**. Double-click on one of them.
5. The chart will be filtered to display the specific Endpoint and Vulnerability, offering more granular data about the vulnerability, including its Category and the FortiClient ID of the device. You can access the CVE and FortiGuard links from this page to learn more.

Only FortiGate models 100D and above support the 24 hour historical data.

Threat Map

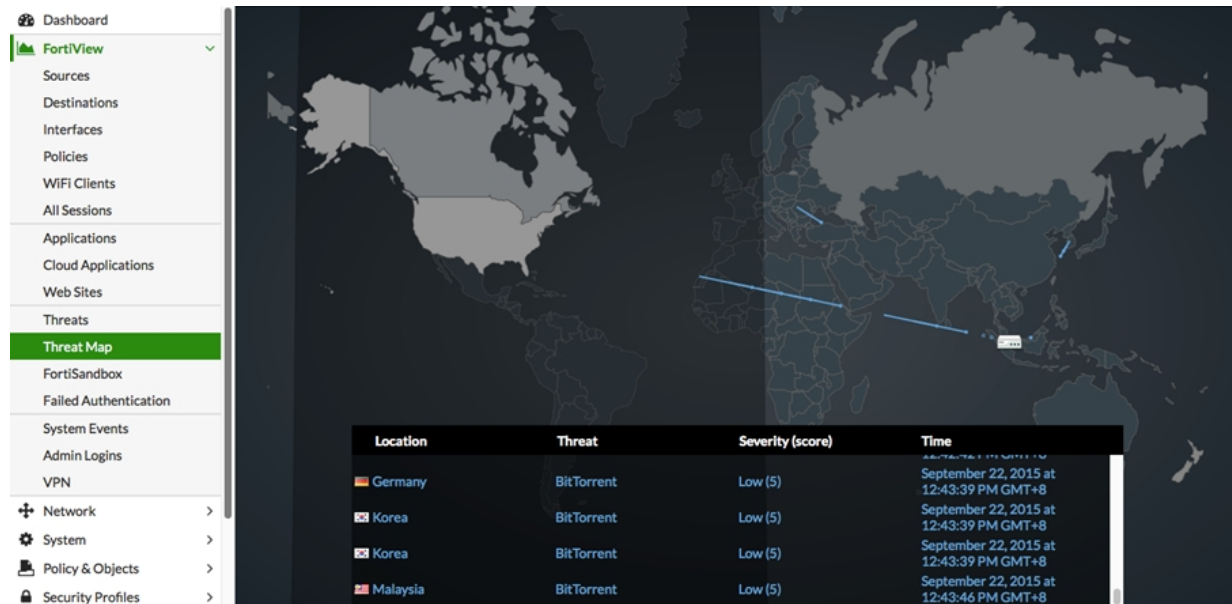

The **Threat Map** console displays network activity by geographic region. Threats from various international destinations will be shown, but only those arriving at your destination, as depicted by the FortiGate. You can place your cursor over the FortiGate's location to display the device name, IP address, and the city name/location.

A visual lists of threats is shown at the bottom, displaying the location, severity, and nature of the attacks. The color gradient of the darts on the map indicate the traffic risk, where red indicates the more critical risk.

Unlike other FortiView consoles, this console has no filtering options, however you can click on any country to drill down into greater (filtered) detail.

Only FortiGate models 100D and above support the 24 hour historical data.

Scenario: Investigate various international threats

The Threat Map console can be used to regionalize areas that you are more interested in, and disregard regions that you are not interested in:

1. Go to **FortiView > Threat Map** to see a real-time map of the globe. This will show various incoming threats from multiple destinations around the world, depending upon where the FortiGate is placed on the map.
2. You are not interested with threats that are being sent to Eastern Europe, however you are concerned with threats that may be sent to a city in North America. Click and drag the FortiGate to the approximate location where you would like to monitor the incoming threats.
3. To see which countries are sending the more severe threats to your region/location, either see where the red darts are coming from, or check the visual lists of threats at the bottom.

Policies

The **Policies** console shows what policies are in affect on your network, what their source and destination interfaces are, how many sessions are in each policy, and what sort of traffic is occurring, represented in bytes sent and received.

This console can be filtered by Country, Destination Interface, Destination IP, Policy, Source, Source Device, and Source Interface. For more on filters, see [Filtering options](#).

Only FortiGate models 100D and above support the 24 hour historical data.

Scenario: Investigate which policies are in effect

You can click on policy IDs to drill down to the policy list and see what policy's are in effect for specific interfaces, how many sessions have occurred, how many of those with the policy have been blocked, and more:

1. Go to **FortiView > Policies**, and double-click on a policy ID to drill down.
2. You will be redirected to a summary screen of the policy ID. From here you can view the source IP of where the policy has been used, what source interface has been using the particular policy, and to verify what sort of threat scores have been measured, both blocked and allowed.

Interfaces

The **Interfaces** console lists the total number of interfaces connected to your network, how many sessions there are in each interface, and what sort of traffic is occurring, represented in both bytes sent and received, and the total bandwidth used.

This console can be filtered by Country, Destination Interface, Destination IP, Policy, Result, Source, and Source Interface. For more on filters, see [Filtering options](#).

Only FortiGate models 100D and above support the 24 hour historical data.

Scenario: Investigate traffic spikes per user

The wan1 interface is showing a higher amount of traffic than usual. A system administrator uses the console to inspect which user (as represented by an IP address) is creating the spike in traffic:

1. Go to **FortiView > Interfaces** and double-click on wan1, or right click and select **Drill Down to Details...**
2. The console will drill down to a summary page of wan1, showing how many bytes are being sent and received, how much bandwidth is being used, and how many sessions are currently using this interface. You see the IP address of the user that is showing the most amount of traffic under **Source**.
3. You can further drill down to see the IP destination, the device, and the applications being used, and other options.

FortiSandbox

The **FortiSandbox** console detects and analyzes advanced attacks designed to bypass traditional security defenses, and has a wide array of features that allow it to prevent future attacks from occurring again.

This console can be filtered by Checksum, File Name, Source, Status, and User Name. For more on filters, see [Filtering options](#).

Only FortiGate models 100D and above support the 24 hour historical data.

All Sessions

The **All Sessions** console provides information about all FortiGate traffic. This console can be filtered by Application, Country, Destination Interface, Destination IP, Destination Port, NAT Source IP, NAT Source Port, Policy, Protocol, Source, Source Interface, Source IP, and Source Port. For more on filters, see [Filtering options](#).

This console has the greatest number of column options to choose from. To choose which columns you wish to view, select the column settings cog at the far right of the columns and select your desired columns. They can then be clicked and dragged in the order that you wish them to appear.

A number of columns available in FortiView are only available in All Sessions. For example, the **Action** column displays the type of response taken to a security event. This function can be used to review what sort of threats were detected, whether the connection was reset due to the detection of a possible threat, and so on. This would be useful to display alongside other columns such as the **Source**, **Destination**, and **Bytes (Sent/Received)** columns, as patterns or inconsistencies can be analyzed.

Similarly, there are a number of filters that are only available in All Sessions, one of which is **Protocol**. This allows you to display the protocol type associated with the selected session, e.g. TCP, FTP, HTTP, HTTPS, and so on.

Scenario: Filtering sessions by port number and application type

From the **All Sessions** console, a wide variety of filters can be applied to sort the session data. In this example, the All Sessions filters will be used to locate a specific user's recent Skype activity.

1. Go to **FortiView > All Sessions**.
2. Select **now** from the **Time Display** options if it is not already selected.
3. Select the **Filter** button, then select **Applications**. This will open a drop-down menu listing the applications that appear in the master session list. From this list, locate and select **Skype**, or type "Skype" into the Search Bar and hit **Enter**. This will filter the session list to only feature Skype usage.
4. Select the **Filter** button again, then select **Destination Port** from the drop-down menu, then locate and select the desired port number. This will add a second filter which will restrict the results to presenting only the Skype data associated with that port number.

Only FortiGate models 100D and above support the 24 hour historical data.

Reference

This section consists of reference information for the various consoles in FortiView. Each console has an assortment of filtering options, drilldown options, and columns that can be displayed. Since many of these options and columns persist through each console, the entire list of options and their descriptions is included below. Attempts have been made to identify the instances where an option or column is only available to a particular console.

This section includes:

Filtering options

When you select the **Add Filter** button, a drop-down list appears with a list of available filtering options. Available options differ based on which console is currently being viewed. The following table explains all of the available filtering options:

Filter option	Description
Accelerated Sessions	You can filter the console on 'FortiASIC' ('Accelerated' versus 'Not Accelerated') sessions.
AP	Filter by Access Point (AP) identification number.
Application	Filter by application name.
Checksum	Filter by checksum value. Checksums are reference digits used to represent the correct datasum of a packet in order to detect errors.
Cloud Application	Filter by cloud application name. Note: This filter is only available in the Cloud Applications console.
Country	Filter by the country from which the source accessed the server.
Destination Interface	Filter by the interface type used by the destination user, e.g. wan1.
Destination IP	Filter by the IP address used by the destination.
Destination Port	Filter by the port used by the destination. Note: This filter is only available in the All Sessions console, (viewing the now time display).
Domain	Filter by domain name. Note: This filter is only available in the Web Sites console.
Event Name	Filter by security event name. Note: This filter is only available in the System Events console.
File Name	Filter by file name. Note: This filter is only available in the FortiSandbox console.
Login Type	Filter by type of login (eg. WEP) associated with the displayed authentication attempt. Note: This filter is only available in the Failed Authentications console.

Filter option	Description
NAT Source IP	Filter by the NAT-translated source IP address. Note: This filter is only available in the All Sessions console, (viewing the now time display).
NAT Source Port	Filter by the NAT-translated source interface. Note: This filter is only available in the All Sessions console, (viewing the now time display).
Policy	Filter by the policy identification number.
Protocol	Filter by the protocol used by the source, e.g. tcp or udp. Note: This filter is only available in the All Sessions console, (viewing the now time display).
Result	Filter by the result of whatever security action was taken by FortiOs in the selected session, eg. Accept (all).
Security Action	Filter by the type of response taken to the security event. The types of possible actions are as follows: Allowed: No threat was detected and the connection was let through. Blocked: A threat was detected and the connection was not let through. Reset: A possible issue was detected and the connection was reset. Traffic Shape: Some data packets may have been delayed to improve system-wide performance.
Severity	Filter by the severity level (Critical , High , Medium or Low) associated with a security event.
Source	Filter by the source IP address.
Source IP	
Source Device	Filter by source device type, e.g. mobile.
Source Interface	Filter by the interface type used by the source user, e.g. wan1.
Source Port	Filter by the source interface. Note: This filter is only available in the All Sessions console, (viewing the now time display).

Filter option	Description
Source SSID	Filter by the Service Set Identifier (SSID) associated with the selected user. An SSID is a case sensitive, 32 character alphanumeric identifier that acts as a password attributed to a mobile device.
Status	Filter by the maliciousness of a file. The types of possible status' are Malicious, High, Medium, Low, Clean, Unknown, and Pending . Note: This filter is only available in the FortiSandbox console.
Threat	Filter by threat name and/or URL
Threat Type	Filter by threat category, e.g. <i>Illegal/Unethical</i> or <i>P2P</i> .
Type	Note: This filter is only available in the Failed Authentications console.
User Name	Filter by user name.
VPN Type	Filter by Virtual Private Network (VPN) protocol type, eg. <i>PPTP</i> . Note: This filter is only available in the VPN console.

Drill-Down Options

Double-click, or right-click, on any entry in a FortiView console and select **Drill Down to Details**, to view the following columns (options vary depending on the console selected):

Drill down options are available for all FortiView consoles except **All Sessions**, **Logical Topology**, and **Physical Topology**.

Option	Description
Applications	Select to drill down by application to view application-related information, including the application name, sessions blocked and allowed, bytes sent and received, and the risk level. You can sort entries by selecting the column header.
Sources	Select to drill down by rows to view source-related information, including IP address, device type, interface type, threat score, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.
Destinations	Select to drill down by destination to view destination-related information, including the IP address and geographic region, interface, threat score, number of sessions blocked and allowed, and bytes sent and received. You can sort entries by selecting the column header.

Option	Description
Countries	Select to drill down by country, including the number of sessions, bytes sent and received, and the bandwidth used. You can sort entries by selecting the column header.
Policies	Select to drill down by the policies in use, including source interface, destination interface, bytes sent and received, and bandwidth used. You can sort entries by selecting the column header.
Source Interfaces	Select to drill down by source interface, including bytes sent and received, and bandwidth used. You can sort entries by selecting the column header.
Destination Interfaces	Select to drill down by destination interface, including bytes sent and received, and bandwidth used. You can sort entries by selecting the column header.
Threats	Select to drill down by threat to view threat-related information, including the threat name, category, threat level, threat score, and number of sessions blocked and allowed. You can sort entries by selecting the column header.
Domains	Select to drill down by domain to view domain-related information, including domain name, category, browsing time, threat weight, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.
Categories	Select to drill down by category to view category-related information, including category name, browsing time, threat score, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.
Sessions	Select to drill down by sessions to view session-related information, including date/time, source, destination IP address and geographic region, application name, security action, security event, and bytes sent/received. You can sort entries by selecting the column header.

Columns displayed

The following columns appear in the initial window of the dashboards. Some columns may only be visible by selecting them from the column drop-down menu. Options vary depending on the dashboard selected.

Column name	Description
Action	<p>Displays the type of response taken to a security event. The types of possible actions are as follows:</p> <ul style="list-style-type: none"> • Allowed: No threat was detected and the connection was let through. • Blocked: A threat was detected and the connection was not let through. • Reset: A possible issue was detected and the connection was reset. • Traffic Shape: Some data packets may have been delayed to improve system-wide performance. <p>Note: This column is only available in the All Sessions console.</p>
Application	<p>Displays the application name and service. When Time Display is set to now, you can access further information about an application by selecting the column entry.</p>
Application Category	<p>Displays the type of application used in the selected session, e.g. video player, social media.</p> <p>Note: This column is only available in the All Sessions console.</p>
Application ID	<p>Displays the identification number associated with the application used in the selected session.</p> <p>Note: This column is only available in the All Sessions console.</p>
Application Risk Risk	<p>Displays the application risk level. You can hover the mouse cursor over the entry in the column for additional information, and select the column header to sort entries by level of risk.</p> <p>Risk uses a 5-point risk rating. The rating system is as follows:</p> <ul style="list-style-type: none"> • Critical: Applications that are used to conceal activity to evade detection. • High: Applications that can cause data leakage, are prone to vulnerabilities, or may download malware. • Medium: Applications that can be misused. • Elevated: Applications that are used for personal communications or can lower productivity. • Low: Business-related applications or other harmless applications.
Bandwidth	<p>Displays information for bandwidth calculated on a per-session level, providing administrators the ability to sort realtime bandwidth usage in descending order.</p>

Column name	Description
Browsing Time	<p>Displays the amount of time a user has spent browsing a web site (in seconds).</p> <p>Note: This column is only available in the Web Sites console, in Categories view..</p>
Bytes (Sent/Received)	<p>Displays the size of sent and received data packets, as measured in bytes. Select the column header to sort the entries by size.</p> <p>Note: This information is available on some consoles as two separate columns: Sent and Received.</p>
Category	Displays the category descriptor appropriate to whatever console is being displayed. For example, threat categories are displayed in the Threats console.
Cloud User	<p>Displays the users accessing cloud applications by IP address.</p> <p>Note: This column is only available in the Cloud Applications console, in Users view.</p>
Configuration Changes	<p>Displays the number of configuration changes made by the user. You can hover the mouse cursor over an entry for additional information.</p> <p>Note: This column is only available in the Admin Logins console.</p>
Connections	<p>Displays the number of VPN connections made by the selected user..</p> <p>Note: This column is only available in the VPN console.</p>
Country	<p>Displays the country from which the selected traffic is originating.</p> <p>Note: This column is only available in the Countries console.</p>
Destination	Displays the destination name, IP address and geographic region.
Destination Country	<p>Displays the country session data is being sent to.</p> <p>Note: This column is only available in the All Sessions console.</p>
Destination Interface	Displays which interface session data is being sent through, e.g. wan1.
Destination Port	<p>Displays the port number of the destination server being used to accept data.</p> <p>Note: This column is only available in the All Sessions console.</p>
Device	Displays the device IP address or Fully Qualified Domain Name (FQDN).

Column name	Description
Domain	Displays the domain associated with the selected web site, e.g. google.com. Note: This column is only available in the Web Sites console.
DST Nat IP NAT Destination	Displays the Network Address Translation (NAT) IP address associated with the destination server. Note: This column is only available in the All Sessions console.
DST Nat Port NAT Destination Port	Displays the Network Address Translation (NAT) port number associated with the destination server. Note: This column is only available in the All Sessions console.
Duration	Displays the amount of time (in seconds) a user has been logged in. Note: This column is only available in the Admin Logins console.
Event Name (Description)	Displays the name and description of the selected security event. Note: This column is only available in the System Events console.
Events	Displays the number of security events that occurred within a selected session. Note: This column is only available in the System Events console.
Expires	Displays the amount of time a session has (in seconds) before it is set to expire. Note: This column is only available in the All Sessions console, in now Time Display view.
Failed Logins	Displays the number of failed login attempts made by an administrator over the specified time period. Note: This column is only available in the Admin Logins console.
Files (Up/Down)	Displays the number of files uploaded and downloaded. Hover the mouse cursor over the entry in the column for additional information. Note: This column is only available in the Cloud Applications console.

Column name	Description
FortiASIC	<p>Displays the type of FortiASIC hardware acceleration used in the specified session, if present.</p> <p>Note: This column is only available in the All Sessions console, in the now Time Display view.</p>
Group	<p>Displays the group ID associated with the selected session.</p> <p>Note: This column is only available in the All Sessions console.</p>
Last Connection Time	<p>Displays the most recent instance of connection to the selected Virtual Private Network (VPN).</p> <p>Note: This column is only available in the VPN console.</p>
Level Threat Level	<p>Displays the threat level. Select the column header to sort entries by threat level.</p>
Log ID	<p>Displays the identification number for the data log associated with this entry.</p> <p>Note: This column is only available in the All Sessions console.</p>
Login IDs	<p>Displays the number of login IDs associated with the selected cloud application.</p> <p>Note: This column is only available in the Cloud Applications console, in Applications view.</p>
Login Type	<p>Displays the type of login (eg. WEP) associated with the displayed authentication attempt.</p> <p>Note: This column is only available in the Failed Authentications console.</p>
Logins	<p>Displays the number of successful logins made by an administrator over the specified time period.</p> <p>Note: This column is only available in the Admin Logins console.</p>
Pending	<p>Note: This column is only available in the FortiSandbox column, in Source view.</p>
Policy ID	<p>Displays the identification number of the policy under which the selected connection was allowed.</p>

Column name	Description
Security Action	<p>Displays the action taken in response to the selected security event. The types of possible actions are as follows:</p> <ul style="list-style-type: none"> • Allowed: No threat was detected and the connection was let through. • Blocked: A threat was detected and the connection was not let through. • Reset: A possible issue was detected and the connection was reset. • Traffic Shape: Some data packets may have been delayed to improve system-wide performance.
Sessions	<p>Displays the number of sessions associated with the selected destination.</p> <p>Note: This column only appears in the Destinations console, in the now Time Display view.</p>
Sessions (Blocked/Allowed)	<p>Displays the number of sessions blocked and allowed by FortiOs.</p> <p>In some consoles, entries can be sorted by number of sessions by selecting the column header..</p>
Severity	Displays the severity level (Critical , High , Medium or Low) associated with the selected security event.
Source	Displays the source IP address and/or user ID, if applicable.
Source Interface	Displays which interface is being used by the destination server (eg. wan1).
Source Port	Displays the port number being used by the source server to send data.
Source SSID	<p>Displays the Service Set Identifier (SSID) associated with the selected user.</p> <p>Note: This column is only available in the Wifi Clients console.</p>
Src NAT IP NAT Source	Displays the Network Address Translation (NAT) IP address associated with the source server.
Src NAT Port NAT Source Port	Displays the Network Address Translation (NAT) port number associated with the source server.

Column name	Description
Status	<p>The types of possible status' are Malicious, High, Medium, Low, Clean, Unknown, and Pending.</p> <p>Note: This console is only available in the FortiSandbox console, in Files view.</p>
Submitted	<p>Displays the number of files submitted to the FortiSandbox for assessment in the selected session.</p> <p>Note: This column is only available in the FortiSandbox console, in Files view.</p>
Threat	Displays the threat type detected in the selected session.
Threat Score (Blocked/Allowed)	Displays the threat score value, a measurement of the total number of threats detected over the course of the session. You can select the column header to sort entries by threat score.
Threat Weight	Displays the threat weight profile associated with the selected session.
Timestamp	Displays the selected session's PHP timestamp.
User	
User Name	Displays the user name associated with the selected administrator.
Videos Played	<p>Displays the number of videos played via cloud applications.</p> <p>Note: This column is only available in the Cloud Applications console.</p>

Risk level indicators

There are currently two consoles within FortiView that display the Risk associated with the console: **Applications** and **Cloud Applications**. Each application pose different levels of risk to the network, represented by a colour code.

The following table identifies each risk level, from least to most severe:

Indicator	Risk	Description
	Green: <i>Risk Level 1</i>	<p>These applications have little to no risk level, with no assigned risk definition. Application file-sharing may result in data leakage, which would be a typical example of a low level risk.</p> <p>An example application would be the Google toolbar, or Dropbox.</p>
	Blue: <i>Risk Level 2</i>	<p>These applications have an elevated risk level and typically use excessive bandwidth. High bandwidth consumption can lead to increased operational costs.</p> <p>An example application would be Bittorrent.</p>
	Yellow: <i>Risk Level 3</i>	<p>These applications have a low risk level and are typically evasive.</p> <p>Evasive applications can lead to compliance risks, and could include applications such as JustinTV and GlypeProxy.</p>
	Orange: <i>Risk Level 4</i>	<p>These applications have a high risk level, and are defined as using both excessive and evasive bandwidth.</p> <p>Example applications would be AutoHideIP and PandoraTV.</p>
	Red: <i>Risk Level 5</i>	<p>Applications that have a high risk level are prone to malware or vulnerabilities that can introduce business continuity risks.</p>

Troubleshooting FortiView

No logging data is displayed

In order for information to appear in the FortiView consoles, disk logging must be selected for the FortiGate unit. To select disk logging, go to **Log & Report > Log Settings**.

Disk logging is disabled by default for some FortiGate units. To enable disk logging, enter the following command in the CLI:

```
config log disk setting
    set status enable
end
```

Only certain FortiGate models support Disk Logging — refer to the [FortiView feature support - platform matrix on page 925](#) for more information.

Logging is enabled, but data is not appearing

Some FortiView consoles require certain features to be enabled and working before they will display any data. For example, the Web Filtering FortiView page requires that a Web Filtering profile be configured in **Security Profiles > Web Filter** and then applied to a policy in **Policy & Objects > IPv4 Policy**.

First, ensure the feature is enabled in **System > Feature Visibility**, and then go to the appropriate page to make sure that the feature is being implemented. If it is working but is producing no data, FortiView will have nothing to display.

Chapter 8 - Fortinet Communication Ports and Protocols

What's new in FortiOS 6.0

The following list contains new communication ports and protocols features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["FortiOS DHCP options and auto DNS hostname for FortiManager details" on page 1011](#)

Introduction

This document contains a series of diagrams and tables showing the communication ports and protocols used between various Fortinet products:

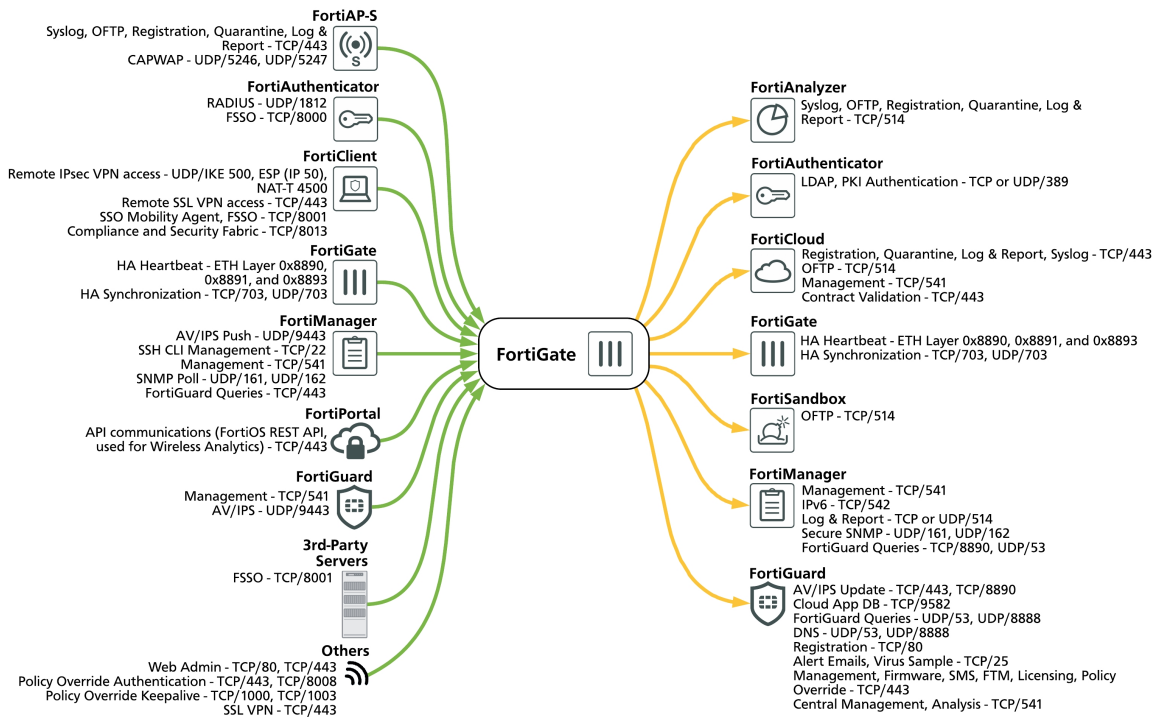

- [FortiGate](#)
- [FortiAnalyzer](#)
- [FortiAP-S](#)
- [FortiAuthenticator](#)
- [FortiClient](#)
- [FortiCloud](#)
- [FortiDB](#)
- [FortiGuard](#)
- [FortiMail](#)
- [FortiManager](#)
- [FortiPortal](#)
- [FortiSandbox](#)
- and [3rd-party servers](#) using FSSO.

Additionally, Fortinet's proprietary protocols are documented, showing what Fortinet products they operate with, how they behave, and how they carry out their roles:

- [FGCP - FortiGate Clustering Protocol](#)
- [FGSP - FortiGate Session Life Support Protocol](#)
- [FGFM - FortiGate to FortiManager Protocol](#)
- [SLBC - Session-aware Load Balancing Cluster](#)
- [Fortinet Security Fabric](#)
- [FortiTelemetry/On-Net/FortiClient Endpoint Compliance](#)
- [FortiGuard](#)
- [FortiLink](#)
- [FortiOS WAN optimization](#)
- [FSSO - Fortinet Single Sign-On](#)
- [OFTP - Optimized Fabric Transfer Protocol](#)
- [FortiClient EMS - Enterprise Management Server](#)

Some protocols contain CLI syntax that control their ports and functionality.

FortiGate open ports

Incoming Ports

Purpose	Protocol/Port
---------	---------------

FortiAP-S	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/443
	CAPWAP	UDP/5246, UDP/5247
FortiAuthenticator	RADIUS	UDP/1812
	FSSO	TCP/8000

Incoming Ports		
Purpose		Protocol/Port
FortiClient	Remote IPsec VPN access	UDP/IKE 500, ESP (IP 50), NAT-T 4500
	Remote SSL VPN access	TCP/443
	SSO Mobility Agent, FSSO	TCP/8001
	Compliance and Security Fabric	TCP/8013 (by default; this port can be customized)
FortiGate	HA Heartbeat	ETH Layer 0x8890, 0x8891, and 0x8893
	HA Synchronization	TCP/703, UDP/703
FortiGuard	Management	TCP/541
	AV/IPS	UDP/9443
FortiManager	AV/IPS Push	UDP/9443
	SSH CLI Management	TCP/22
	Management	TCP/541
	SNMP Poll	UDP/161, UDP/162
	FortiGuard Queries	TCP/443
	API communications (FortiOS REST API, used for Wireless Analytics)	TCP/443
Others	Web Admin	TCP/80, TCP/443
	Policy Override Authentication	TCP/443, TCP/8008
	Policy Override Keepalive	TCP/1000, TCP/1003
	SSL VPN	TCP/443
3rd-Party Servers	FSSO	TCP/8001 (by default; this port can be customized)

Outgoing Ports		
Purpose		Protocol/Port
FortiAnalyzer	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
FortiAuthenticator	LDAP, PKI Authentication	TCP or UDP/389
FortiCloud	Registration, Quarantine, Log & Report, Syslog	TCP/443
	OFTP	TCP/514
	Management	TCP/541
	Contract Validation	TCP/443
FortiGate	HA Heartbeat	ETH Layer 0x8890, 0x8891, and 0x8893
	HA Synchronization	TCP/703, UDP/703
FortiGuard	AV/IPS Update	TCP/443, TCP/8890
	Cloud App DB	TCP/9582
	FortiGuard Queries	UDP/53, UDP/8888
	DNS	UDP/53, UDP/8888
	Registration	TCP/80
	Alert Email, Virus Sample	TCP/25
	Management, Firmware, SMS, FTM, Licensing, Policy Override	TCP/443
	Central Management, Analysis	TCP/541
FortiManager	Management	TCP/541
	IPv6	TCP/542
	Log & Report	TCP or UDP/514
	Secure SNMP	UDP/161, UDP/162
	FortiGuard Queries	TCP/8890, UDP/53
FortiSandbox	OFTP	TCP/514

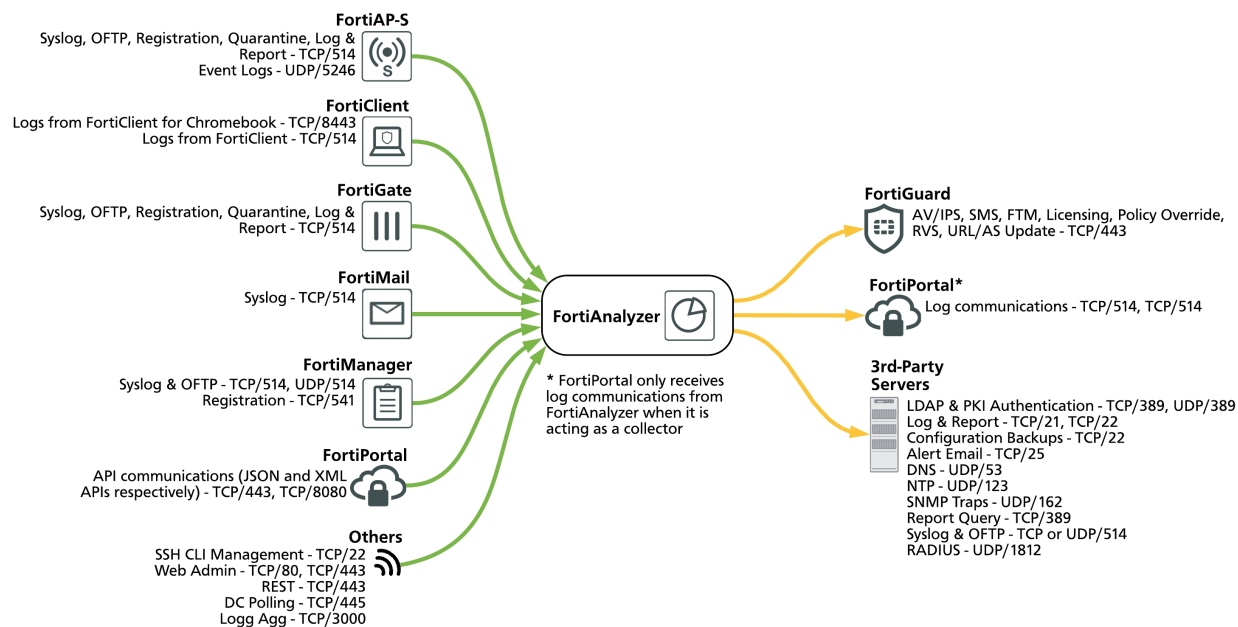

Outgoing Ports		
Purpose		Protocol/Port
Others	FSSO	TCP/8001 (by default; this port can be customized)

Note that, while a proxy is configured, FortiGate uses the following URLs to access the FortiGuard Distribution Network (FDN):

- **update.fortiguard.net**
- **service.fortiguard.net**
- **support.fortinet.com**

FortiAnalyzer open ports

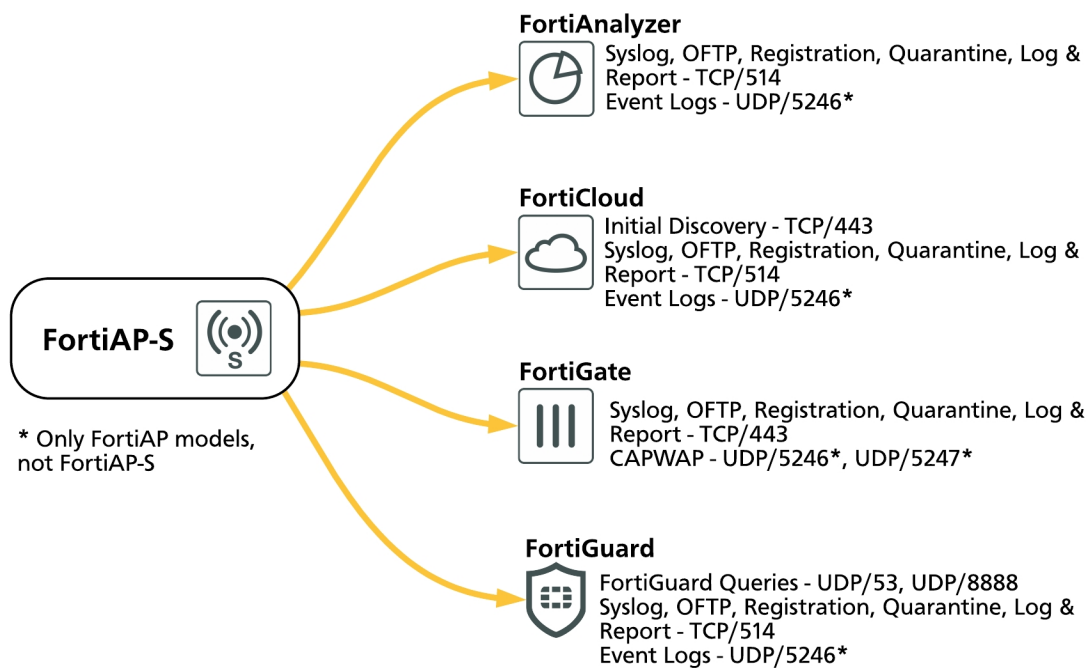

Incoming Ports		
Purpose		Protocol/Port
FortiAP-S	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246
FortiClient	Logs from FortiClient for Chromebook	TCP/8443
	Logs from FortiClient (FortiClient must connect to FortiGate or EMS to send logs to FortiAnalyzer)	TCP/514
FortiGate	Syslog, OFTP, Registration, Quarantine, Log & Reports	TCP/514
FortiMail	Syslog	UDP/514
FortiManager	Syslog & OFTP	TCP/514, UDP/514
	Registration	TCP/541

Incoming Ports		
Purpose		Protocol/Port
FortiPortal	API communications (JSON and XML APIs respectively)	TCP/443, TCP/8080
Others	SSH CLI Management	TCP/22
	Web Admin	TCP/80, TCP/443
	REST	TCP/443
	DC Polling	TCP/445
	Logg Agg	TCP/3000

Outgoing Ports table		
Purpose		Protocol/Port
FortiGuard	AV/IPS, SMS, FTM, Licensing, Policy Override, RVS, URL/AS Update	TCP/443
FortiPortal (FortiPortal only receives log communications from FortiAnalyzer when it is acting as a collector)	Log communications	TCP/514, UDP/514
3rd-Party Servers	LDAP & PKI Authentication	TCP/389, UDP/389
	Log & Report	TCP/21, TCP/22
	Configuration Backups	TCP/22
	Alert Email	TCP/25
	DNS	UDP/53
	NTP	UDP/123
	SNMP Traps	UDP/162
	Report Query	TCP/389
	Syslog & OFTP	TCP or UDP/514
	RADIUS	UDP/1812

FortiAP-S open ports

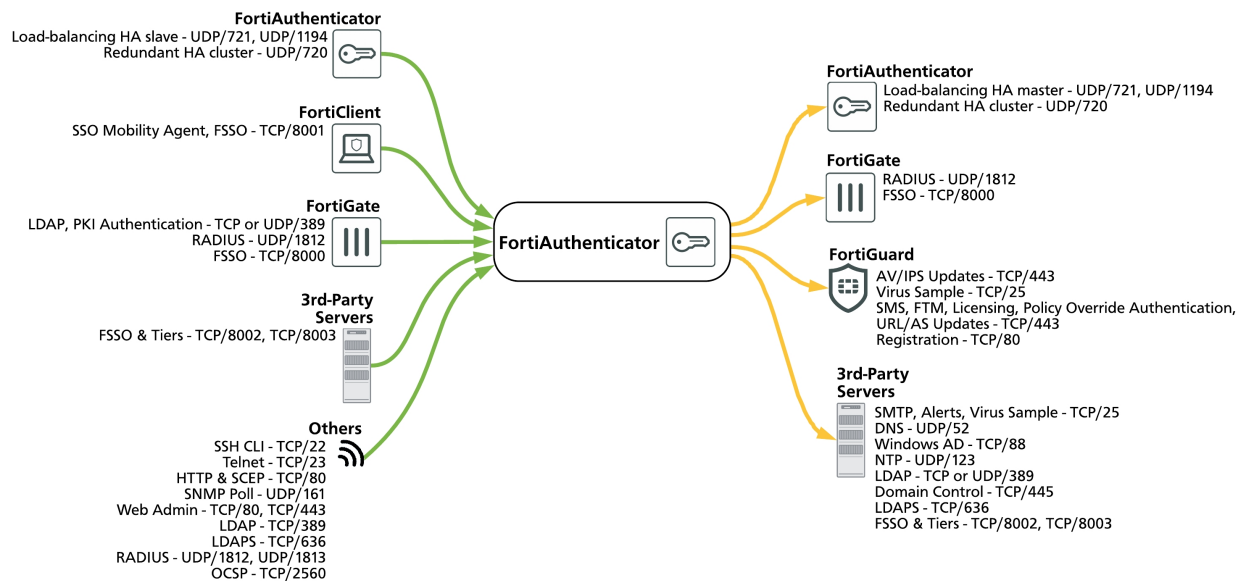

Outgoing Ports		
Purpose		Protocol/Port
FortiAnalyzer	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246*
FortiCloud	Initial Discovery	TCP/443
	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246*
FortiGate	Syslog, Registration, Quarantine, Log & Report	TCP/443
	CAPWAP	UDP/5246*, UDP/5247*

Outgoing Ports		
Purpose		Protocol/Port
FortiGuard	FortiGuard Queries	UDP/53, UDP/8888
	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246*

FortiAuthenticator open ports

Incoming Ports

Purpose	Protocol/Port
FortiAuthenticator	(HA) HA heartbeat
	LB slave sync
FortiClient	SSO Mobility Agent, FSSO
FortiGate	LDAP, PKI Authentication
	RADIUS
	FSSO

Incoming Ports		
Purpose		Protocol/Port
Others	SSH CLI	TCP/22
	Telnet	TCP/23
	HTTP & SCEP	TCP/80
	SNMP Poll	UDP/161
	Web Admin	TCP/80, TCP/443
	LDAP	TCP/389
	LDAPS	TCP/636
	RADIUS	UDP/1812, UDP/1813
	OCSP	TCP/2560
3rd-Party Servers	FSSO & Tiers	TCP/8002, TCP/8003

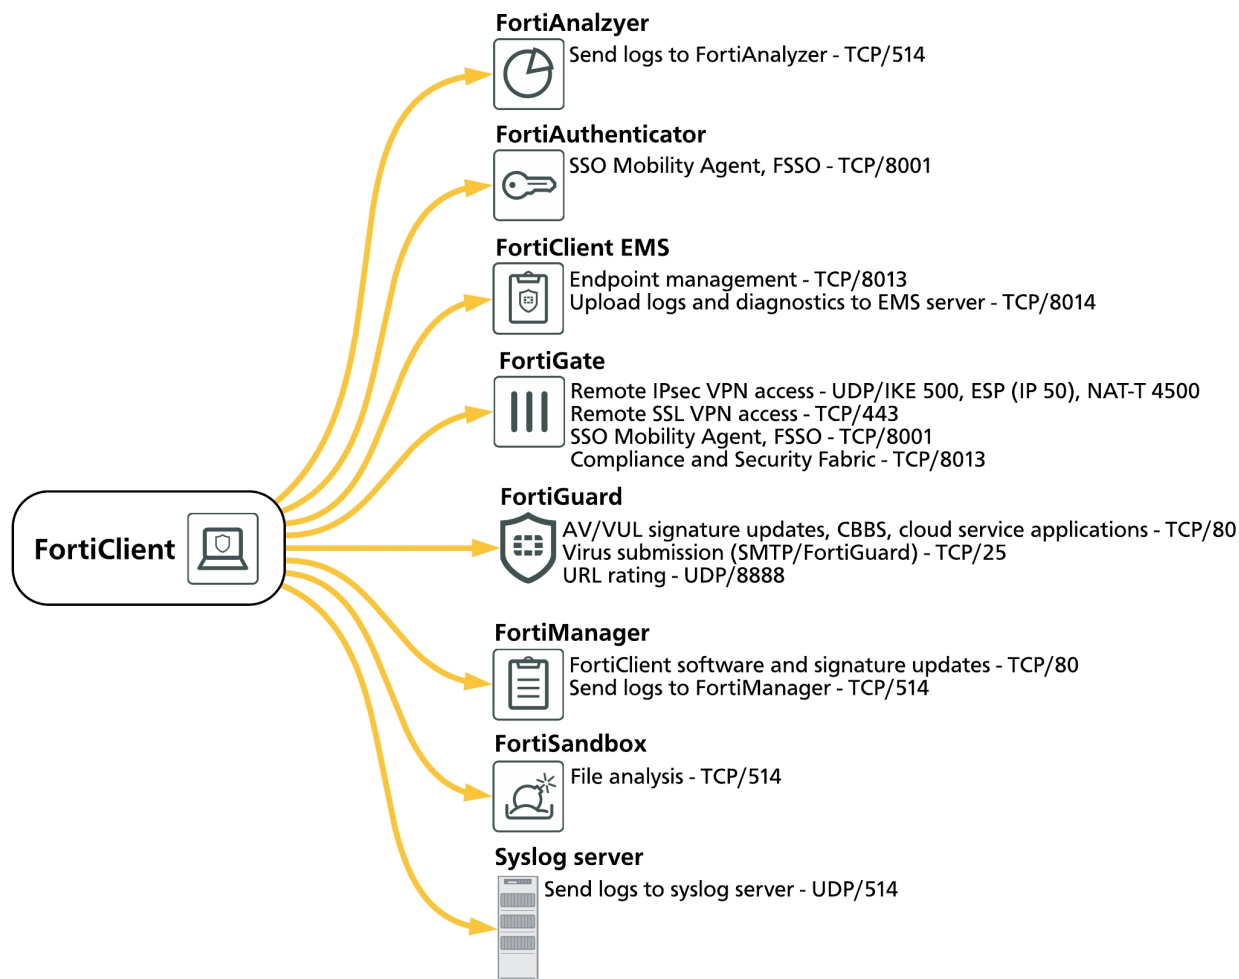

Outgoing Ports		
Purpose		Protocol/Port
FortiAuthenticator	(HA) HA heartbeat	UDP/720
	(LB slave) LB slave sync	UDP/721, UDP/1194
FortiGate	RADIUS	UDP/1812
	FSSO	TCP/8000
FortiGuard	AV/IPS Updates	TCP/443
	Virus Sample	TCP/25
	SMS, FTM, Licensing, Policy Override Authentication, URL/AS Updates	TCP/443
	Registration	TCP/80

Outgoing Ports		
Purpose		Protocol/Port
3rd-Party Servers	SMTP, Alerts, Virus Sample	TCP/25
	DNS	UDP/52
	Windows AD	TCP/88
	NTP	UDP/123
	LDAP	TCP or UDP389
	Domain Control	TCP/445
	LDAPS	TCP/636
	FSSO & Tiers	TCP/8002, TCP/8003

FortiClient open ports

The following diagrams and tables show the distinct communications for each FortiClient product.

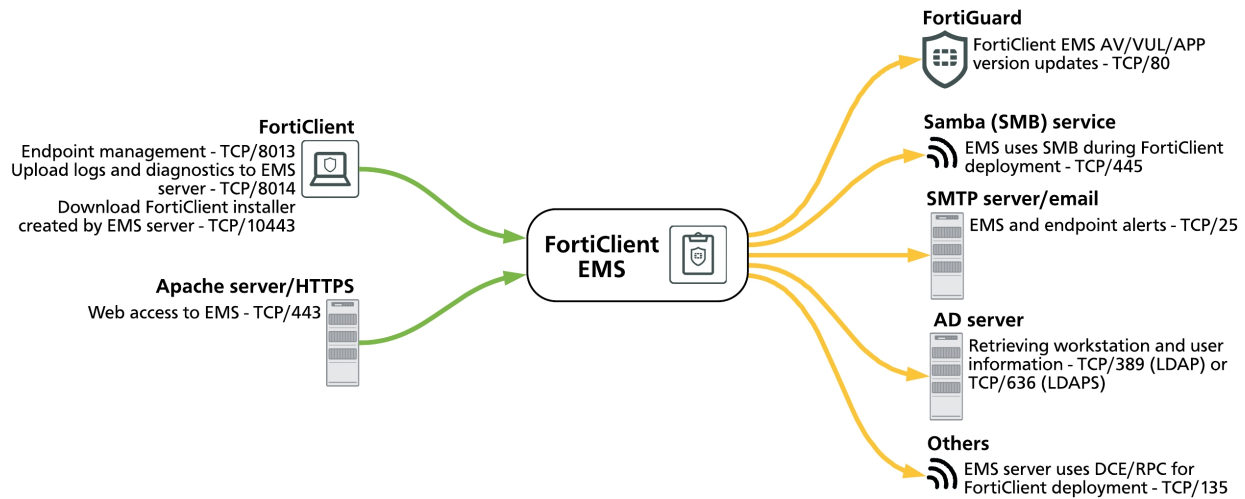

FortiClient

Outgoing Ports		
Purpose		Protocol/Port
FortiAnalyzer	Send logs to FortiAnalyzer (FortiClient must connect to FortiGate or EMS to send logs to FortiAnalyzer)	TCP/514
FortiAuthenticator	SSO Mobility Agent, FSSO	TCP/8001

Outgoing Ports		
Purpose		Protocol/Port
FortiClient EMS	Endpoint management	TCP/8013
	Upload logs and diagnostics to EMS server	TCP/8014
FortiGate	Remote IPsec VPN access	UDP/IKE 500, ESP (IP 50), NAT-T 4500
	Remote SSL VPN access	TCP/443 (by default; this port can be customized)
	SSO Mobility Agent, FSSO	TCP/8001
	Compliance and Security Fabric	TCP/8013 (by default; this port can be customized)
FortiGuard	AV/VUL signatures update, Cloud-based behavior scan (CBBS)/applications that use cloud services	TCP/80
	Virus submission (SMTP/FortiGuard)	TCP/25
	URL rating	UDP/8888 (by default; this port can be changed to port 53 via XML config file)
FortiManager	Select a FortiManager to be used for FortiClient signature updates	TCP/80 (by default; this port can be customized)
	Send logs to FortiManager (FortiClient must connect to FortiGate or EMS to send logs to FortiManager)	TCP/514
FortiSandbox	File analysis	TCP/514
Syslog server	Send logs to syslog server	UDP/514

FortiClient EMS

Incoming Ports

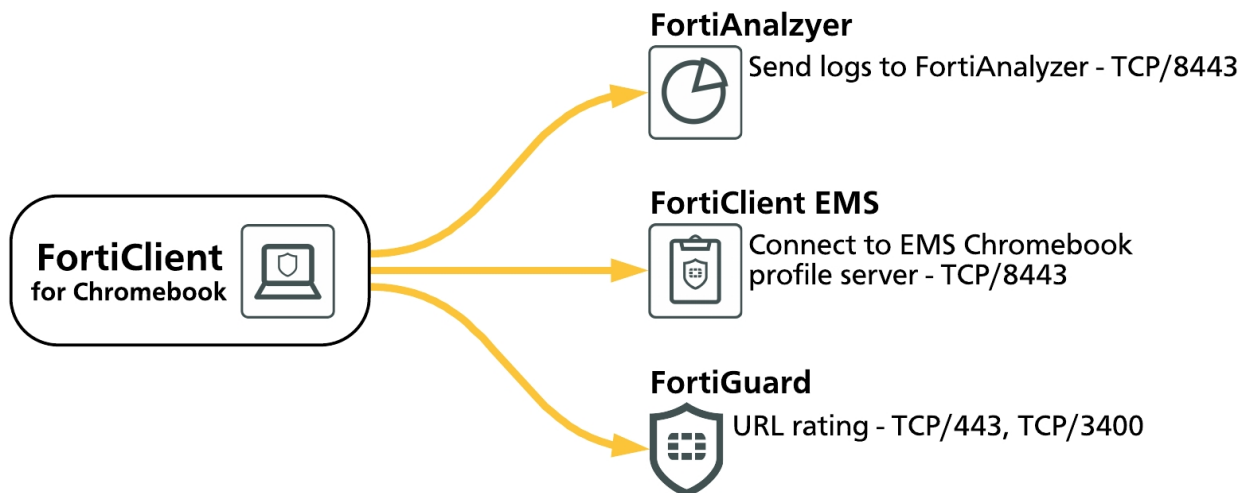

Purpose	Protocol/Port
FortiClient Endpoint management	TCP/8013 (by default; this port can be customized)
Upload logs and diagnostics to EMS server	TCP/8014
Download FortiClient installer created by EMS server	TCP/10443
Apache server/HTTPS Web access to EMS	TCP/443

Outgoing Ports

Purpose	Protocol/Port
FortiGuard FortiClient EMS AV/VUL/APP version updates	TCP/80
Samba (SMB) service EMS uses SMB during FortiClient deployment	TCP/445
SMTP server/email EMS and endpoint alerts	TCP/25

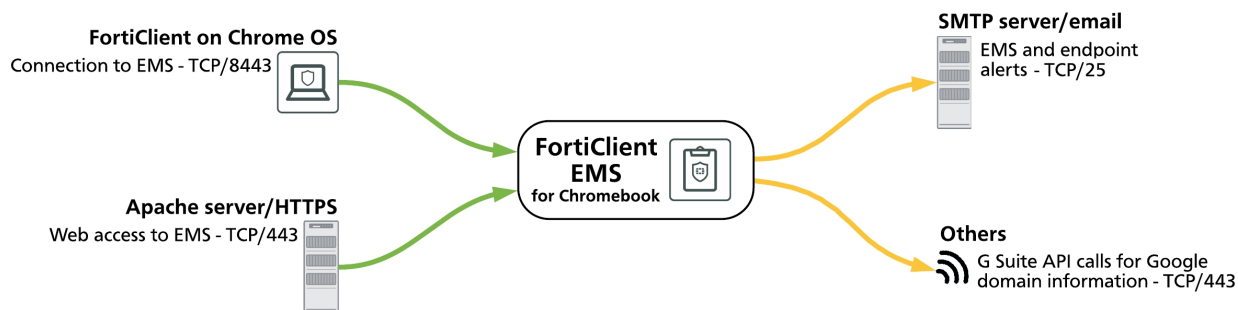

Outgoing Ports		
Purpose		Protocol/Port
AD server	Retrieving workstation and user information	TCP/389 or TCP/636 (for LDAP or LDAPS respectively)
Others	EMS server uses Distributed Computing Environment/Remote Procedure Calls (DCE/RPC) for FortiClient deployment	TCP/135

FortiClient for Chromebook

Outgoing Ports		
Purpose		Protocol/Port
FortiAnalyzer	Send logs to FortiAnalyzer	TCP/8443
FortiClient EMS	Connect to EMS Chromebook profile server	TCP/8443
FortiGuard	URL rating	TCP/443, TCP/3400

FortiClient EMS for Chromebook

Incoming Ports

Purpose	Protocol/Port
---------	---------------

FortiClient for Chromebook	Connection to EMS	TCP/8443
-----------------------------------	-------------------	----------

Apache server/HTTPS	Web access to EMS	TCP/443
----------------------------	-------------------	---------

Outgoing Ports

Purpose	Protocol/Port
---------	---------------

SMTP server/email	EMS and endpoint alerts	TCP/25
--------------------------	-------------------------	--------

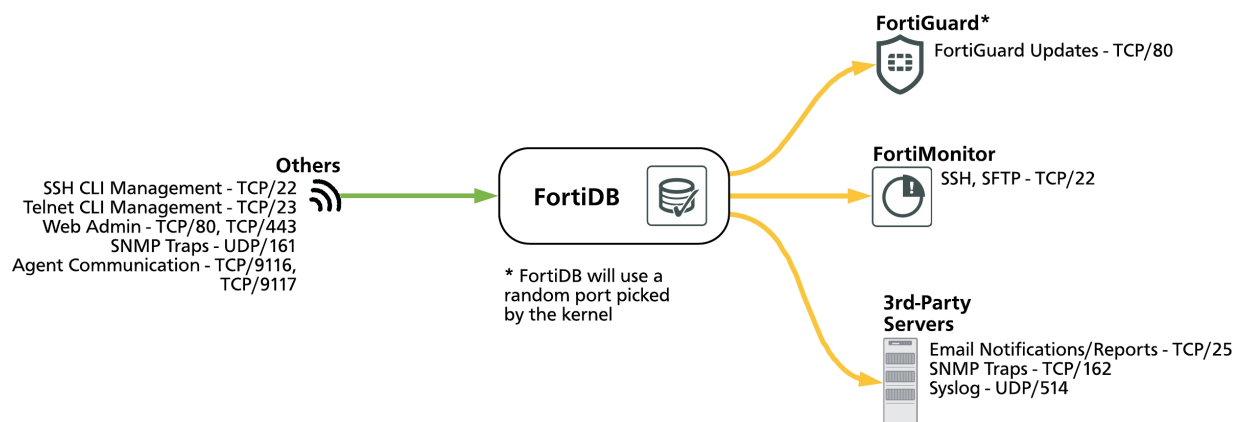

Others	G Suite API calls for Google domain information	TCP/443
---------------	---	---------

FortiCloud open ports

Incoming Ports		
Purpose		Protocol/Port
FortiAP-S	Initial Discovery	TCP/443
	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246
FortiGate	Registration, Quarantine, Log & Report, Syslog	TCP/443
	OFTP	TCP/514
	Management	TCP/541
	Contract Validation	TCP/443
Outgoing Ports		
Purpose		Protocol/Port
FortiGuard	Registration	TCP/443

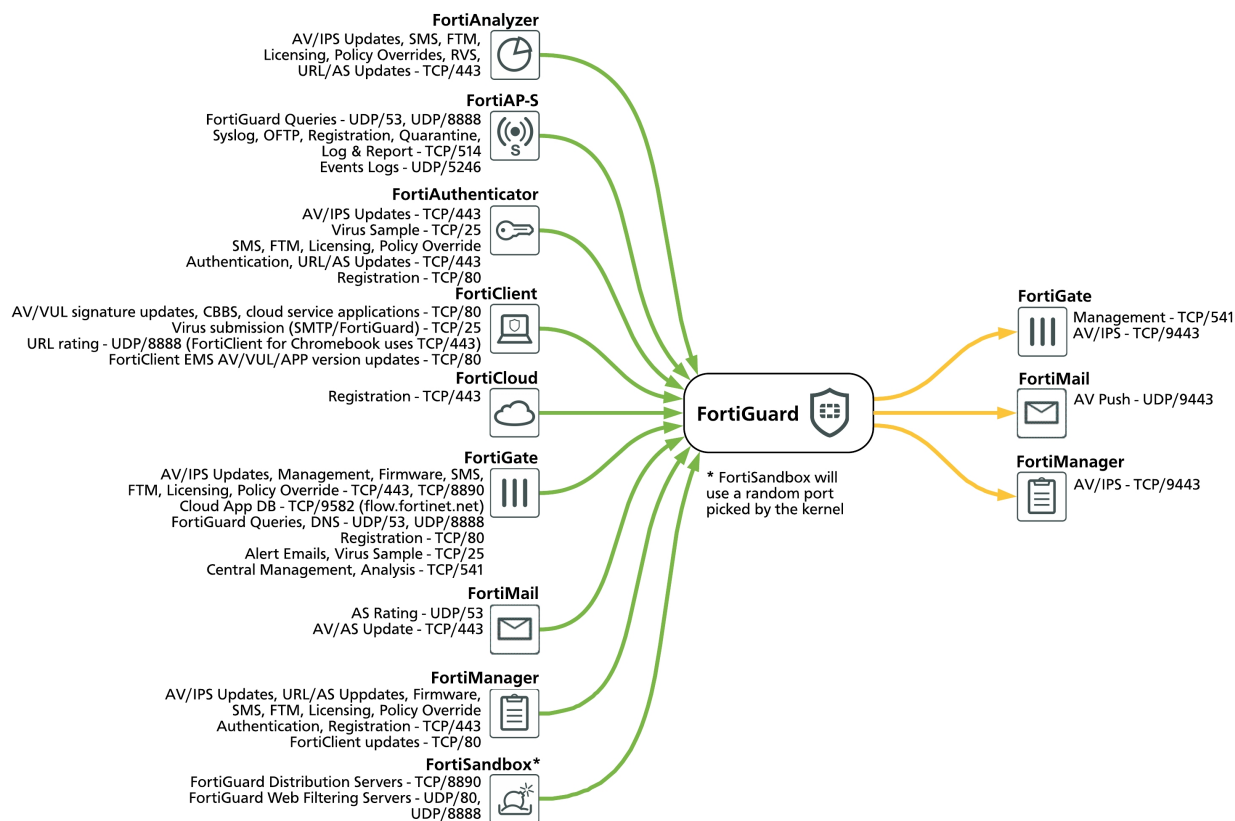

FortiDB open ports

Incoming Ports		
Purpose		Protocol/Port
Others	SSH CLI Management	TCP/22
	Telnet CLI Management	TCP/23
	Web Admin	TCP/80, TCP/443
	SNMP Traps	UDP/161
	Agent Communication	TCP/9116, TCP/9117

Outgoing Ports		
Purpose		Protocol/Port
FortiGuard (FortiDB will use a random port picked by the kernel)	FortiGuard Updates	TCP/80
FortiMonitor	SSH, SFTP	TCP/22
3rd-Party Servers	Email Notifications/Reports	TCP/25
	SNMP Traps	UDP/162
	Syslog	UDP/514

FortiGuard open ports

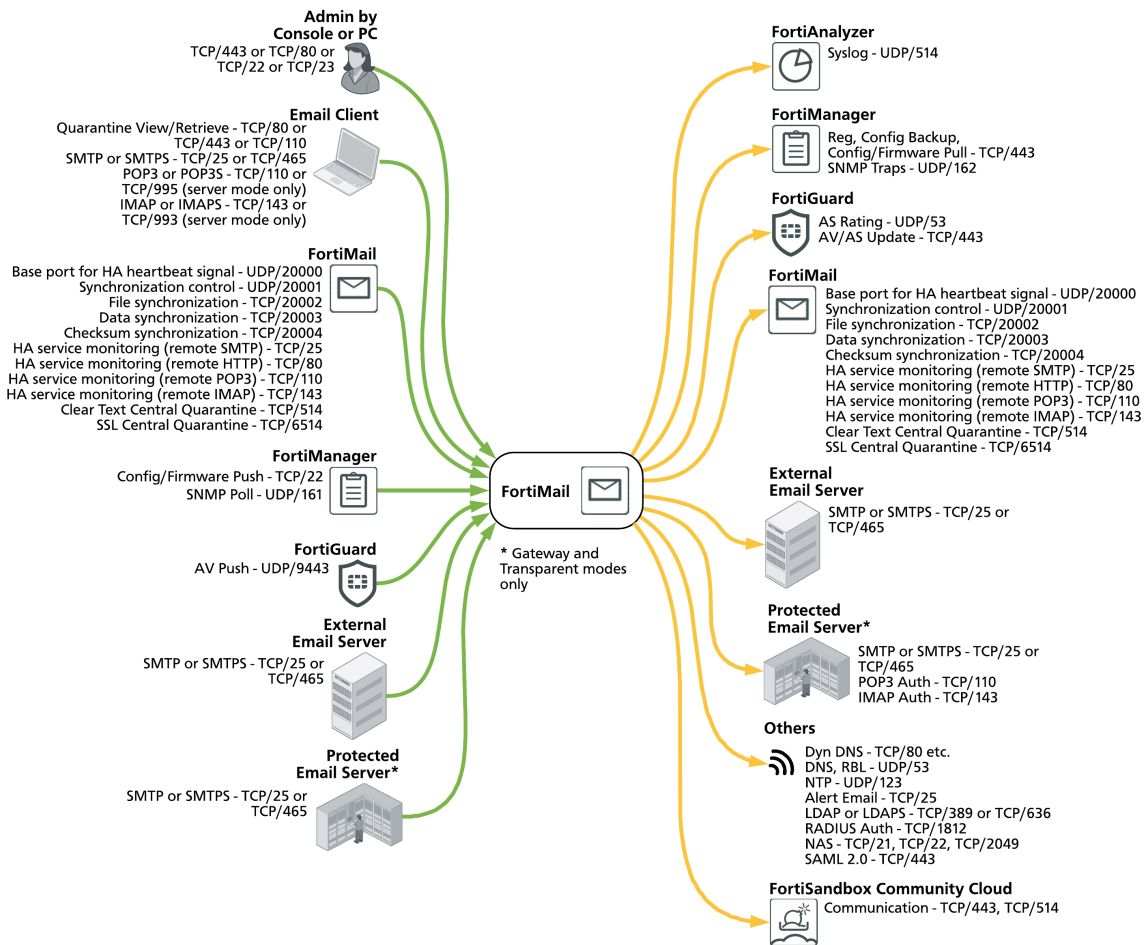

Incoming Ports

Purpose	Protocol/Port
FortiAnalyzer	AV/IPS Updates, SMS, FTM, Licensing, Policy Overrides, RVS, URL/AS Update TCP/443
FortiAP-S	FortiGuard Queries UDP/53, UDP/8888
	Syslog, OFTP, Registration, Quarantine, Log & Report TCP/514
	Event Logs UDP/5246

Incoming Ports		
Purpose		Protocol/Port
FortiAuthenticator	AV/IPS Updates	TCP/443
	Virus Sample	TCP/25
	SMS, FTM, Licensing, Policy Override Authentication, URL/AS Updates	TCP/443
	Registration	TCP/80
FortiClient	AV/VUL signatures update, Cloud-based behavior scan (CBBS)/applications that use cloud services	TCP/80
	Virus submission (SMTP/FortiGuard)	TCP/25
	URL rating	UDP/8888 (by default; this port can be changed to port 53 via XML config file) Note: FortiClient for Chromebooks contacts FortiGuard for URL ratings via TCP/443
	FortiClient EMS AV/VUL/APP version updates *	TCP/80
FortiCloud	Registration	TCP/443
FortiGate	AV/IPS Update, Management, Firmware, SMS, FTM, Licensing, Policy Override	TCP/443, TCP/8890
	Cloud App DB	TCP/9582 (flow.fortinet.net)
	FortiGuard Queries, DNS	UDP/53, UDP/8888
	Registration	TCP/80
	Alert Emails, Virus Sample	TCP/25
	Central Management, Analysis	TCP/541
FortiMail	AS Rating	UDP/53
	AV/AS Update	TCP/443

Incoming Ports		
Purpose		Protocol/Port
FortiManager	AV/IPS Updates, URL/AS Update, Firmware, SMS, FTM, Licensing, Policy Override Authentication, Registration	TCP/443
	FortiClient updates	TCP/80
FortiSandbox (FortiSandbox will use a random port picked by the kernel)	FortiGuard Distribution Servers	TCP/8890
	FortiGuard Web Filtering Servers	UDP/53, UDP/8888
Outgoing Ports		
Purpose		Protocol/Port
FortiGate	Management	TCP/541
	AV/IPS	UDP/9443
FortiMail	AV Push	UDP/9443
FortiManager	AV/IPS	UDP/9443

FortiMail open ports

When operating in its default configuration, FortiMail does not accept TCP or UDP connections on any port except port1 and port2 network interfaces, which accept:

- ICMP pings,
- HTTPS connections on TCP/443,
- and SSH connections on TCP/22.

Incoming Ports		
Purpose		Protocol/Port
Admin by Console or PC	SSH, Telnet, HTTP, SSH, Console	TCP/443 or TCP/80 or TCP/22 or TCP/23
Email Client	Quarantine View/Retrieve	TCP/80 or TCP/443 or TCP/110
	SMTP or SMTPS	TCP/25 or TCP/465
	POP3 or POP3S	TCP/110 or TCP/995 (server mode only)
	IMAP or IMAPS	TCP/143 or TCP/993 (server mode only)
	WebDAV and CalDAV	TCP/8008
FortiMail	Base port for HA heartbeat signal	UDP/20000
	Synchronization control	UDP/20001
	File synchronization	TCP/20002
	Data synchronization	TCP/20003
	Checksum synchronization	TCP/20004
	HA service monitoring (remote SMTP)	TCP/25
	HA service monitoring (remote HTTP)	TCP/80
	HA service monitoring (remote POP3)	TCP/110
	HA service monitoring (remote IMAP)	TCP/143
	Clear Text Central Quarantine	TCP/514
	SSL Central Quarantine	TCP/6514
FortiManager	SNMP Poll	TCP/161
	AV Push	
FortiGuard	AV Push	UDP/9443

Incoming Ports		
Purpose		Protocol/Port
External Email Server	SMTP or SMTPS	TCP/25 or 465
	Storage: iSCSI, NFS	TCP/3260 (iSCSI), TCP/2049 (NFS)
	Config Backup	SFTP / FTP
	Mail Data Backup	NFS, SMB/CIFS, SSH, external USB (direct connected), iSCSI
Protected Email Server	SMTP or SMTPS	TCP/25 or 465

Outgoing Ports		
Purpose		Protocol/Port
FortiAnalyzer	OFTP	UDP/514
FortiManager	SNMP Traps	UDP/162
	AV/AS Query	
FortiGuard	AS Rating	UDP/53 or 8888, 8889
	AV/AS Update	TCP/443

Outgoing Ports		
Purpose		Protocol/Port
FortiMail	Base port for HA heartbeat signal	UDP/20000
	Synchronization control	UDP/20001
	File synchronization	TCP/20002
	Data synchronization	TCP/20003
	Checksum synchronization	TCP/20004
	HA service monitoring (remote SMTP)	TCP/25
	HA service monitoring (remote HTTP)	TCP/80
	HA service monitoring (remote POP3)	TCP/110
	HA service monitoring (remote IMAP)	TCP/143
	Clear Text Central Quarantine	TCP/514
	SSL Central Quarantine	TCP/6514
External Email Server	SMTP or SMTPS	TCP/25 or TCP/465
Protected Email Server	SMTP or SMTPS	TCP/25 or TCP/465
	POP3 Auth	TCP/110
	IMAP Auth	TCP/143
Others	Dyn DNS	TCP/80 *
	DNS, RBL	UDP/53
	NTP	UDP/123
	Alert Email	TCP/25
	LDAP or LDAPS	TCP/389 or TCP/636
	RADIUS Auth	TCP/1812
	NAS	TCP/21, TCP/22, TCP/2049
	OCSP (for PKI user)	TCP/80, or defined by certificate

Outgoing Ports		
Purpose		Protocol/Port
FortiSandbox / FortiSandbox Cloud	Communication	TCP/443, TCP/514

* - FortiMail generates outbound traffic and sends an HTTP SYN request via TCP/80. The Fortinet RSS Feed widget provides a convenient display of the latest security advisories and discovered threats from Fortinet. Also, if an email message contains a shortened URI that redirects to another URI, it would cause FortiMail to send an HTTP SYN request to the shortened URI to get the redirected URI.

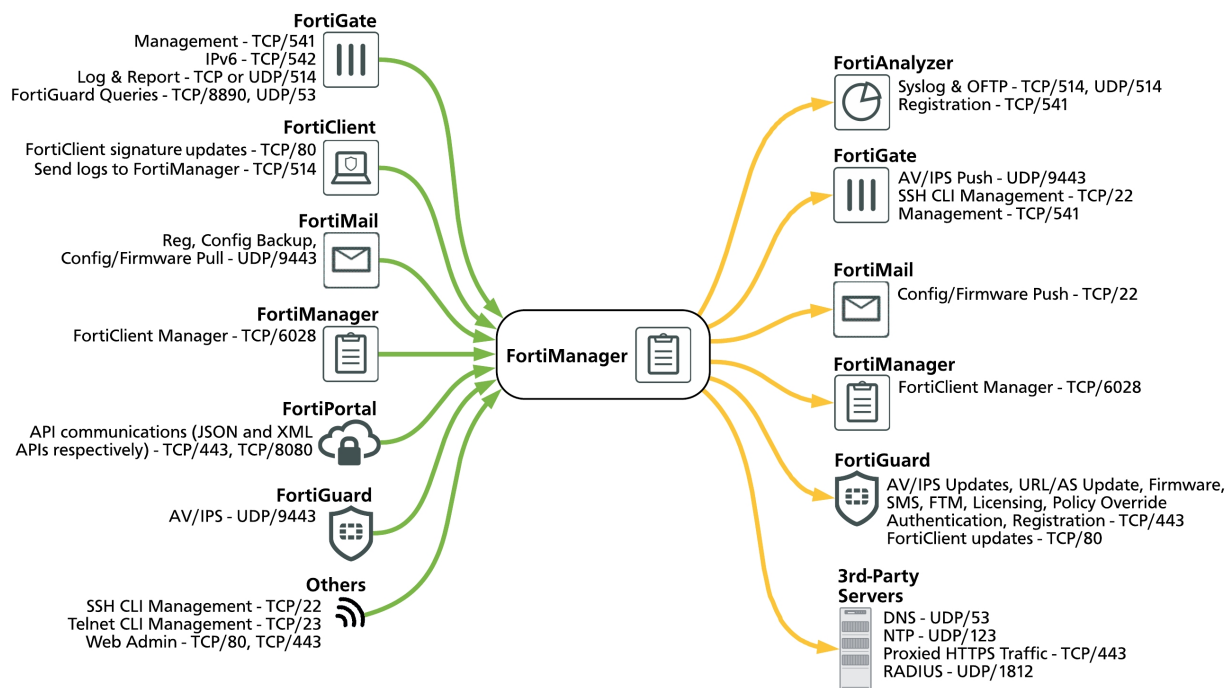

Note that FortiMail uses the following URLs to access the FortiGuard Distribution Network (FDN):

- **update.fortiguard.net**
- **service.fortiguard.net**
- **support.fortinet.com**

Furthermore, FortiMail performs these queries and updates listed below using the following ports and protocols:

- FortiGuard Anti-Spam rating queries: UDP/53, 8888, 8889
- FortiGuard AntiVirus Push updates: UDP/9443
- FortiGuard Anti-Spam or AntiVirus updates: TCP/443

FortiManager open ports

Incoming Ports		
Purpose		Protocol/Port
FortiGate	Management	TCP/541
	IPv6	TCP/542
	Log & Report	TCP or UDP/514
	FortiGuard Queries	TCP/8890, UDP/53
FortiClient	Select a FortiManager to be used for FortiClient signature updates	TCP/80 (by default; this port can be customized)
	Send logs to FortiManager (FortiClient must connect to FortiGate or EMS to send logs to FortiManager)	TCP/514
FortiGuard	AV/IPS	UDP/9443

Incoming Ports		
Purpose		Protocol/Port
FortiMail	Registration	UDP/9443
	AV/AS Query	
FortiManager	FortiClient Manager	TCP/6028
FortiPortal	API communications (JSON and XML APIs respectively)	TCP/443, TCP/8080
Others	SSH CLI Management	TCP/22
	Telnet CLI Management	TCP/23
	Web Admin	TCP/80, TCP/443

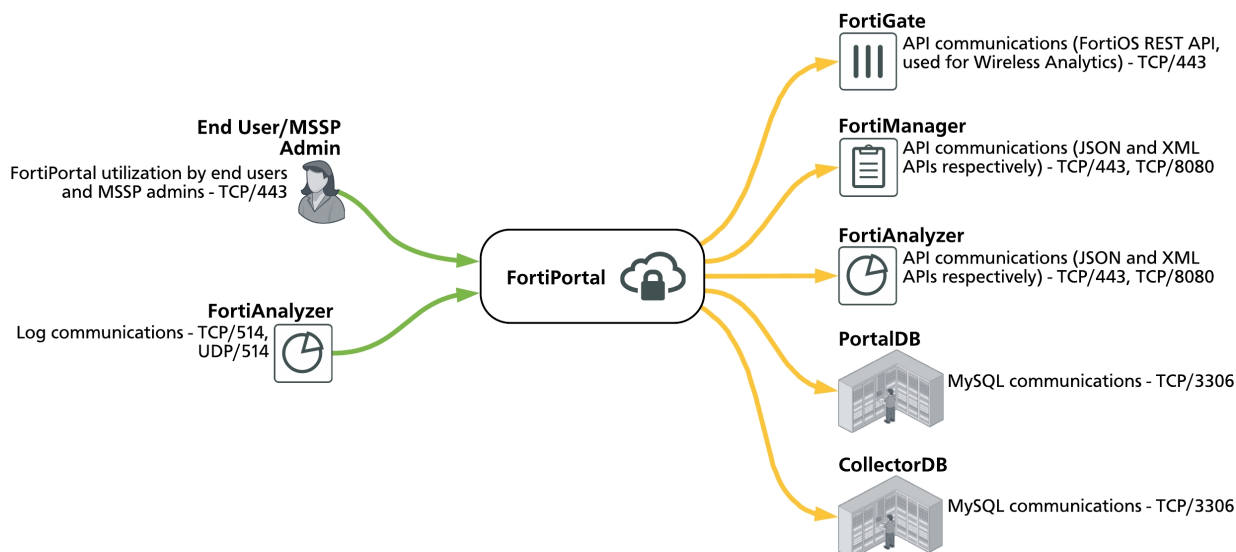

Outgoing Ports		
Purpose		Protocol/Port
FortiAnalyzer	Syslog & OFTP	TCP/514, UDP/514
	Registration	TCP/541
FortiGate	AV/IPS Push	UDP/9443
	SSH CLI Management	TCP/22
	Management	TCP/541
FortiGuard	AV/IPS Updates, URL/AS Update, Firmware, SMS, FTM, Licensing, Policy Override Authentication, Registration	TCP/443
	FortiClient updates	TCP/80
FortiMail	AV Push	
FortiManager	FortiClient Manager	TCP/6028
3rd-Party Servers	DNS	UDP/53
	NTP	UDP/123
	Proxied HTTPS Traffic	TCP/443
	RADIUS	UDP/1812

Note that, while a proxy is configured, FortiManager uses the following URLs to access the FortiGuard Distribution Network (FDN) for the following updates:

- **fds1.fortinet.com** - FortiGate AV/IPS package downloads
- **guard.fortinet.net** - Webfilter/Anti-Spam DB and AVfileQuery DB downloads
- **forticlient.fortinet.com** - FortiClient signature package downloads
- **fgd1.fortigate.com:8888** - FortiClient Webfilter queries to FortiGuard

FortiPortal open ports

Incoming Ports

Purpose

FortiAnalyzer

API communications (JSON and XML APIs respectively)

TCP/443, TCP/8080

Outgoing Ports table		
Purpose		Protocol/Port
PortalDB	MySQL communications	TCP/3306
CollectorDB	MySQL communications	TCP/3306

FortiSandbox open ports

Incoming Ports		
Purpose		Protocol/Port
FortiGate	OFTP	TCP/514
FortiClient	File analysis	TCP/514
Others	SSH CLI Management	TCP/22
	Telnet CLI Management	TCP/23
	Web Admin	TCP/80, TCP/443
	OFTP Communication with FortiGate & FortiMail	TCP/514
	Third-party proxy server for ICAP servers	ICAP: TCP/1344 ICAPS: TCP/11344

Outgoing Ports		
Purpose		Protocol/Port
FortiGuard (FortiSandbox will use a random port picked by the kernel)	FortiGuard Distribution Servers	TCP/8890
	FortiGuard Web Filtering Servers	UDP/53, UDP/8888

Outgoing Ports		
Purpose		Protocol/Port
FortiSandbox Community Cloud (FortiSandbox will use a random port picked by the kernel)	Upload detected malware information	TCP/443, UDP/53

Note that FortiSandbox uses the following FQDNs to access the FortiSandbox Community Cloud, depending on which protocol and port is used:

- TCP/443: **fqdl.fortinet.net**
- UDP/53: **fqsrv.fortinet.net**

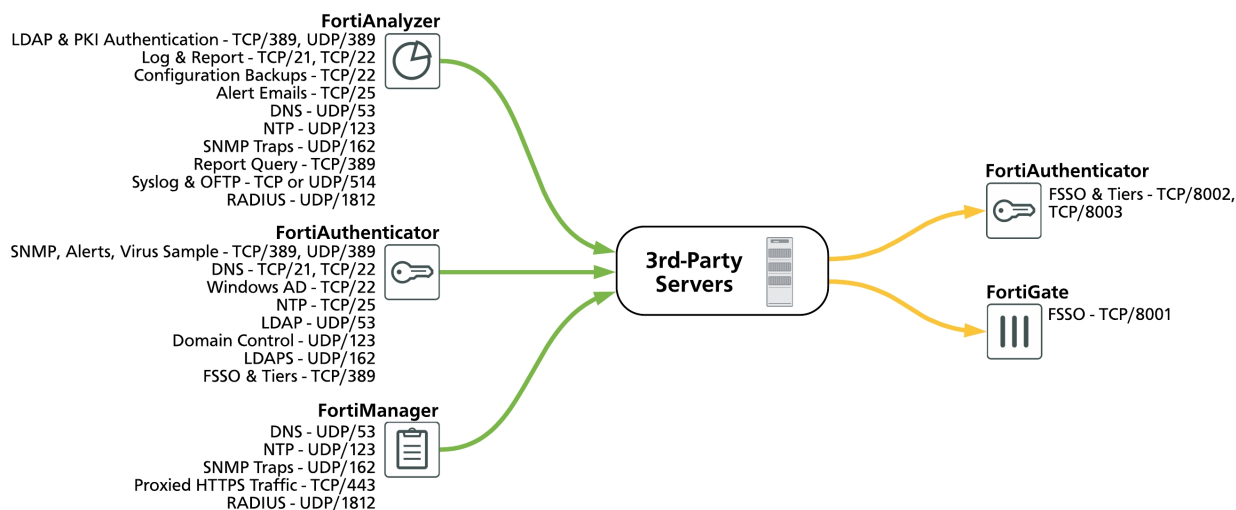

Services and port numbers required for FortiSandbox

The tables above show all the services required for FortiSandbox to function correctly. You can use the diagnostic FortiSandbox command `test-network` to verify that all the services are allowed by the upstream. If the result is `Passed`, then there is no issue. If there is an issue with a specific service, it will be shown in the command output, and inform you which port needs to be opened.

This command checks:

- VM Internet access
- Internet connection
- System DNS resolve speed
- VM DNS resolve speed
- Ping speed
- Wget speed
- Web Filtering service
- FortiSandbox Community Cloud service

3rd-party servers open ports

Incoming Ports		
Purpose		Protocol/Port
FortiAnalyzer	LDAP & PKI Authentication	TCP/389, UDP/389
	Log & Report	TCP/21, TCP/22
	Configuration Backups	TCP/22

	RADIUS	UDP/1812

Outgoing Ports		
Purpose		Protocol/Port
FortiAuthenticator	FSSO & Tiers	TCP/8002, TCP/8003
FortiGate	FSSO	TCP/8001 (by default; this port can be customized)

Fortinet proprietary protocols

The following section provides a full list of Fortinet's proprietary protocols, their purposes, and what ports they operate on:

- FGCP - FortiGate Clustering Protocol
- FGSP - FortiGate Session Life Support Protocol
- FGFM - FortiGate to FortiManager Protocol
- SLBC - Session-aware Load Balancing Cluster
- Fortinet Security Fabric
- FortiTelemetry/On-Net/FortiClient Endpoint Compliance
- FortiGuard
- FortiLink
- FortiOS WAN optimization
- FSSO - Fortinet Single Sign-On
- OFTP - Optimized Fabric Transfer Protocol
- FortiClient EMS - Enterprise Management Server

FGCP - FortiGate Clustering Protocol

In an active-passive HA configuration, the FortiGate Clustering Protocol (FGCP) provides failover protection, whereby the cluster can provide FortiGate services even when one of the cluster units loses connection. FGCP is also a Layer 2 heartbeat that specifies how FortiGate units communicate in an HA cluster and keeps the cluster operating.

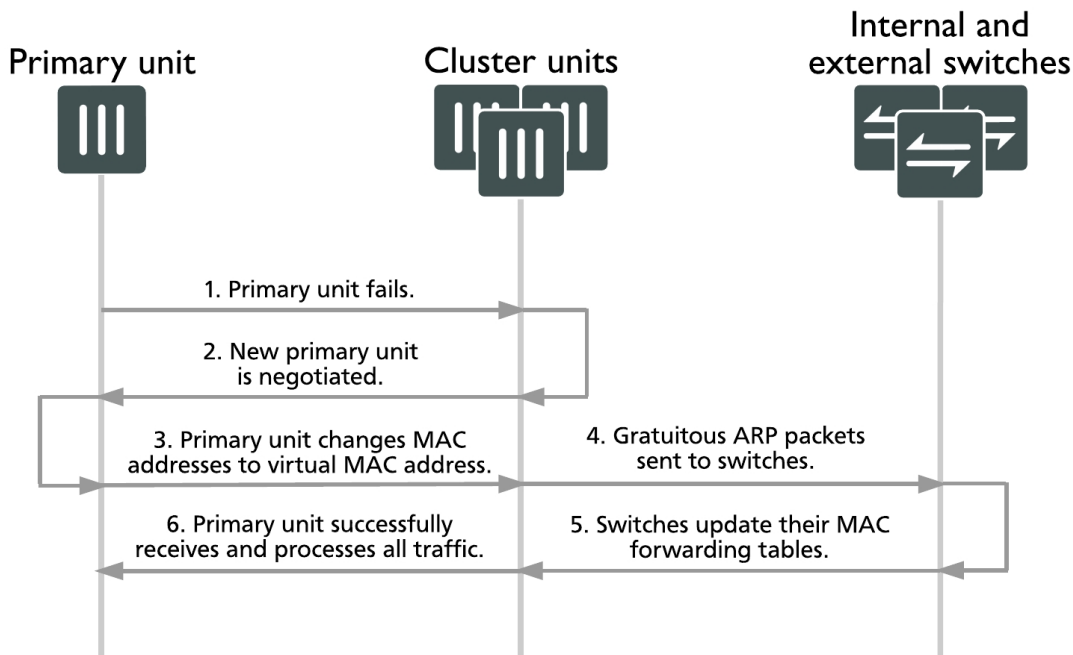

You cannot mix FGCP and SLBC clusters in the same chassis.

The FortiGate's HA Heartbeat listens on ports TCP/703, TCP/23, or ETH Layer 2/8890.

Virtual MAC addresses

FGCP assigns virtual MAC addresses to each primary unit interface in an HA cluster. Virtual MAC addresses are in place so that, if a failover occurs, the new primary unit interfaces will have the same MAC addresses as the failed primary unit interfaces. If the MAC addresses were to change after a failover, the network would take longer to recover because all attached network devices would have to learn the new MAC addresses before they could communicate with the cluster.

If a cluster is operating in Transparent mode, FGCP assigns a virtual MAC address for the primary unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

When a cluster starts up, after a failover, the primary unit sends gratuitous ARP packets to update the switches connected to the cluster interfaces with the virtual MAC address. The switches update their MAC forwarding tables with this MAC address. As a result, the switches direct all network traffic to the primary unit. Depending on the cluster configuration, the primary unit either processes this network traffic itself or load balances the network traffic among all of the cluster units.

You cannot disable sending gratuitous ARP packets, but you can change the number of packets that are sent (1-60 ARP packets) by entering the following command:

```
config system ha
    set arps <integer>
end
```

You can change the time between ARP packets (1-20 seconds) by entering the following command:

```
config system ha
    set arps-interval <integer>
end
```

Assigning virtual MAC addresses

Virtual MAC addresses are determined based on the following formula:

00-09-0f-09-<group-id_hex>-<vcluster_integer><idx>

where:

- **<group-id_hex>**: The HA group ID for the cluster converted to hexadecimal. The table below lists some example virtual MAC addresses set for each group ID:

Integer Group ID	Hexadecimal Group ID
0	00
1	01
2	02
3	03
...	...
10	0a
11	0b
...	...
63	3f
...	...
255	ff

- **<vcluster_integer>**: This value is 0 for virtual cluster 1 and 2 for virtual cluster 2. If virtual domains are not enabled, HA sets the virtual cluster to 1 and by default all interfaces are in the root virtual domain. Including virtual cluster and virtual domain factors in the virtual MAC address formula means that the same formula can be used whether or not virtual domains and virtual clustering is enabled.
- **<idx>**: The index number of the interface. In NAT/Route mode, interfaces are numbered from 0 to x (where x is the number of interfaces). The interfaces are listed in alphabetical order on the web-based manager and CLI. The interface at the top of the interface list is first in alphabetical order by name and has an index of 0. The second interface in the list has an index of 1 and so on. In Transparent mode, the index number for the management IP address is 0.

Every FortiGate unit physical interface has two MAC addresses: the current hardware address and the permanent hardware address. The permanent hardware address cannot be changed, as it is the actual MAC address of the interface hardware. The current hardware address can be changed, but only when a FortiGate unit is **not** operating in HA. For an operating cluster, the current hardware address of each cluster unit interface is changed to the HA virtual MAC address by the FGCP.

You cannot change an interface MAC address and you cannot view MAC addresses from the system interface CLI command.

You can use the `get hardware nic <interface_name_str>` (or `diagnose hardware deviceinfo nic <interface_str>`) command to display both MAC addresses for any FortiGate interface. This command displays hardware information for the specified interface, including the current hardware address (as `Current_HWaddr`) and the permanent hardware address (as `Permanent_HWaddr`). For some interfaces, the current hardware address is displayed as `MAC`.

Failover protection

FGCP supports three kinds of failover protection:

1. **Device failover:** Automatically replaces a failed device and restarts traffic flow with minimal impact on the network. All subordinate units in an active-passive HA cluster are constantly waiting to negotiate to become primary units. Only the heartbeat packets sent by the primary unit keep the subordinate units from becoming primary units. Each received heartbeat packet resets negotiation timers in the subordinate units. If this timer is allowed to run out because the subordinate units do not receive heartbeat packets from the primary unit, the subordinate units assume that the primary unit has failed, and negotiate to become primary units themselves. The default time interval between HA heartbeats is 200 ms.
2. **Link failover:** Maintains traffic flow if a link fails. In this case, the primary unit does not stop operating, and therefore participates in the negotiation of selecting a new primary unit. The old primary unit then joins the cluster as a subordinate unit. Furthermore, any subordinate units with a link failure are unlikely to become the primary unit in future negotiations.
3. **Session failover:** With session failover (also called session pickup) enabled, the primary unit informs the subordinate units of changes to the primary unit connection and state tables, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster. This helps new primary units resume communication sessions with minimal loss of data, avoiding the need to restart active sessions.

Synchronization of configurations

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. However, there are certain settings that are not synchronized between cluster units:

- HA override
- HA device priority

- The virtual cluster priority
- The FortiGate unit host name
- The HA priority setting for a ping server (or dead gateway detection) configuration
- The system interface settings of the HA reserved management interface
- The HA default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.

You can disable configuration synchronization by entering the following command:

```
config system ha
    set sync-config disable
end
```

The command `execute ha synchronize` can be used to perform a manual synchronization.

The FGCP heartbeat operates on TCP port 703 with an independent IP address not assigned to any FortiGate interface. You can create an FGCP cluster of up to four FortiGate units. Below is an example of FGCP used to create an HA cluster installed between an internal network and the Internet.

FGCP HA provides a solution for two key requirements of critical enterprise networking: enhanced reliability and increased performance, through device, link, and remote link failover protection. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures.

Before configuring an FGCP HA cluster, make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Heartbeat traffic, such as FGCP, uses multicast on port number 6065 and uses link-local IPv4 addresses in the 169.254.0.x range. HA heartbeat packets have an Ethertype field value of **0x8890**.

Synchronization traffic, such as FGSP, uses unicast on port number 6066 and the IP address 239.0.0.2. HA sessions that synchronize the cluster have an Ethertype field value of **0x8893**.

The HA IP addresses are hard-coded and cannot be configured.

How to set up FGCP clustering

This example describes how to enhance the reliability of a network protected by a FortiGate unit by adding a second FortiGate unit to create a FortiGate Clustering Protocol (FGCP) HA cluster. The FortiGate already on the network will be configured to become the primary unit by increasing its device priority and enabling override. The new FortiGate will be prepared by setting it to factory defaults to wipe any configuration changes. Then it will be licensed, configured for HA, and then connected to the FortiGate already on the network. The new FortiGate becomes the backup unit and its configuration is overwritten by the primary unit.

If you have not already done so, register the primary FortiGate and apply licenses to it before setting up the cluster. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMs). You can also install any third-party certificates on the primary FortiGate before forming the cluster.

The FortiGates should be running the same FortiOS firmware version, and their interfaces should not be configured to get their addresses from DHCP or PPPoE.

Configuring the primary FortiGate

1. Connect to the primary FortiGate and go to **Dashboard > Main > System Information**. Change the unit's **Host Name** to identify it as the primary FortiGate.

You can also enter this CLI command:

```
config system global
  set hostname Primary_FortiGate
end
```

2. You then need to set the HA mode to active-passive. Enter the following CLI command to set the HA mode to active-passive, set a group name and password, increase the device priority to a higher value (for example, 250) and enable override:

```
config system ha
  set mode a-p
  set group-name My-HA-Cluster
```

```
set password
set priority 250
set override enable
set hbdev ha1 50 ha2 50
end
```

This command also selects ha1 and ha2 to be the heartbeat interfaces, with their priorities set to 50. Enabling override and increasing the priority ensures that this FortiGate should become the primary unit.

You can configure these settings in the GUI under **System > HA**, however the override can *only* be enabled in the CLI.

Configuring the backup FortiGate

1. Enter the CLI command below to reset the new FortiGate to factory default settings (skip this step if the FortiGate is fresh from the factory). It is recommended to set it back to factory defaults to reduce the chance of synchronization problems.:

```
execute factoryreset
```

2. Make sure to change the firmware running on the new FortiGate to the same version running on the primary unit, register, and apply licenses to it before adding it to the cluster.
3. Then go to **Dashboard > Main > System Information**. Change the unit's **Host Name** to identify it as the backup FortiGate.

You can also enter this CLI command:

```
config system global
  set hostname Backup_FortiGate
end
```

4. Duplicate the primary unit's HA settings, except make sure to set the backup device's priority to a lower value and do *not* enable override.

Connecting the cluster

Connect the HA cluster as shown in the initial diagram above. Making these connections will disrupt network traffic as you disconnect and re-connect cables.

When connected, the primary and backup FortiGates find each other and negotiate to form an HA cluster. The primary unit synchronizes its configuration with the backup FortiGate. Forming the cluster happens automatically with minimal or no disruption to network traffic.

Heartbeat packet ethertypes

Normal IP packets are 802.3 packets that have an ethernet type (ethertype) field value of 0x0800. Ethertype values other than 0x0800 are understood as level 2 frames rather than IP packets.

By default, HA heartbeat packets use the following ethertypes:

- HA heartbeat packets for NAT/Route mode clusters use Ethertype 0x8890. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ethertype of these packets using the `ha-eth-type` option under `config system ha`.
- HA heartbeat packets for Transparent mode clusters use Ethertype 0x8891. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ethertype of these packets using the `hc-eth-type` option under `config system ha`.

- HA telnet sessions between cluster units over HA heartbeat links use Ethertype 0x8893. The telnet sessions allow an administrator to connect between FortiGates in the cluster using the `execute ha manage` command. You can change the Ethertype of these packets using the `l2ep-eth-type` option under `config system ha`.

Because heartbeat packets are recognized as level 2 frames, the switches and routers on your heartbeat network that connect to heartbeat interfaces must be configured to allow them. If level2 frames are dropped by these network devices, heartbeat traffic will not be allowed between the cluster units.

Some third-party network equipment may use packets with these Ethernets for other purposes. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethernets 0x8890, 0x8891, and 0x8893 to pass.

Alternatively, you can use the following CLI options to change the Ethernets of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex>
  set hc-eth-type <hc_ethertype_4-digit_hex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For example, use the following command to change the Ethertype of the HA heartbeat packets from 0x8890 to 0x8895 and to change the Ethertype of HA Telnet session packets from 0x8891 to 0x889f:

```
config system ha
  set ha-eth-type 8895
  set l2ep-eth-type 889f
end
```

Enabling or disabling HA heartbeat encryption and authentication

You can enable HA heartbeat encryption and authentication to encrypt and authenticate HA heartbeat packets. HA heartbeat packets should be encrypted and authenticated if the cluster interfaces that send HA heartbeat packets are also connected to your networks.

If HA heartbeat packets are not encrypted the cluster password and changes to the cluster configuration could be exposed and an attacker may be able to sniff HA packets to get cluster information. Enabling HA heartbeat message authentication prevents an attacker from creating false HA heartbeat messages. False HA heartbeat messages could affect the stability of the cluster.

HA heartbeat encryption and authentication are disabled by default. Enabling HA encryption and authentication could reduce cluster performance. Use the following CLI command to enable HA heartbeat encryption and authentication.

```
config system ha
  set authentication enable
  set encryption enable
end
```

HA authentication and encryption uses AES-128 for encryption and SHA1 for authentication.

FGSP - FortiGate Session Life Support Protocol

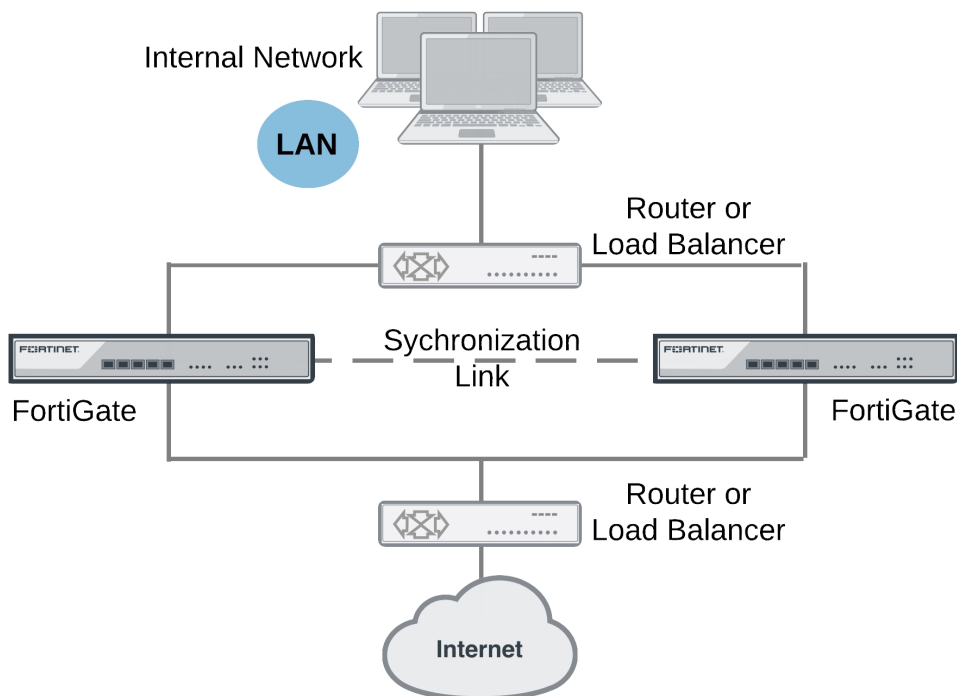

FortiGate Session Life Support Protocol (FGSP) distributes sessions between two FortiGate units and the FGSP performs session synchronization. If one of the peers fails, session failover occurs and active sessions fail over to the peer that is still operating. This failover occurs without any loss of data. Also, the external routers or load balancers will detect the failover and re-distribute all sessions to the peer that is still operating. The two FortiGate units must be the same model and must be running the same firmware.

Note that you cannot configure FGSP HA when FGCP HA is enabled.

You can also use the `config system cluster-sync` command to configure FGSP between two FortiGate units.

The FortiGate's HA Heartbeat listens on ports TCP/703, TCP/23, or ETH Layer 2/8890.

In previous versions of FortiOS, FGSP was called TCP session synchronization or standalone session synchronization. However, FGSP has been expanded to include both IPv4 and IPv6 TCP, UDP, ICMP, expectation, NAT sessions, and IPsec tunnels.

Configuration synchronization

Configuration synchronization can also be performed, allowing you to make configuration changes once for both FortiGate units instead of requiring multiple configuration changes on each FortiGate unit. However interface IP addresses, BGP neighbor settings, and other settings that identify the FortiGate unit on the network are not synchronized. You can enable configuration synchronization by entering the following command:

```
config system ha
    set standalone-config-sync enable
end
```

UDP and ICMP (connectionless) session synchronization

In many configurations, due to their non-stateful nature, UDP and ICMP sessions don't need to be synchronized to naturally failover. However, if it is required, you can configure the FGSP to also synchronize UDP and ICMP sessions by entering the following command:

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

Expectation (asymmetric) session synchronization

Synchronizing asymmetric traffic can be very useful in situations where multiple Internet connections from different ISPs are spread across two FortiGates.

The FGSP enforces firewall policies for asymmetric traffic, including cases where the TCP 3-way handshake is split between two FortiGates. For example, FGT-A receives the TCP-SYN, FGT-B receives the TCP-SYN-ACK, and FGT-A receives the TCP-ACK. Under normal conditions a firewall will drop this connection since the 3-way handshake was not seen by the same firewall. However two FortiGates with FGSP configured will be able to properly pass this traffic since the firewall sessions are synchronized.

If traffic will be highly asymmetric, as described above, the following command must be enabled on both FortiGates:

```
config system ha
    set session-pickup enable
    set session-pickup-expectation enable
end
```

Security profile inspection with asymmetric and symmetric traffic

Security profile inspection, flow or proxy based, is **not** expected to work properly if the traffic in the session is load balanced across more than one FortiGate in either direction. However, flow-based inspection should be used in FGSP deployments.

For symmetric traffic, security profile inspection can be used but with the following limitations:

- No session synchronization for the sessions inspected using proxy-based inspection. Sessions will drop and need to be reestablished after data path failover.
- Sessions with flow-based inspection will failover, and inspection of sessions after a failover may not work.

Improving session synchronization performance

Two HA configuration options are available to reduce the performance impact of enabling session failover (also known as session pickup): reducing the number of sessions that are synchronized by adding a session pickup delay, and using more FortiGate interfaces for session synchronization.

Reducing the number of sessions that are synchronized

If session pickup is enabled, as soon as new sessions are added to the primary unit session table they are synchronized to the other cluster units. Enable the session-pickup-delay CLI option to reduce the number of sessions that are synchronized by synchronizing sessions only if they remain active for more than 30 seconds. Enabling this option could greatly reduce the number of sessions that are synchronized if a cluster typically processes very many short duration sessions, which is typical of most HTTP traffic for example.

Use the following command to enable a 30 second session pickup delay:

```
config system ha
    set session-pickup-delay enable
end
```

Enabling session pickup delay means that if a failover occurs more sessions may not be resumed after a failover. In most cases short duration sessions can be restarted with only a minor traffic interruption. However, if you notice too many sessions not resuming after a failover you might want to disable this setting.

Using multiple FortiGate interfaces for session synchronization

Using the `session-sync-dev` option, you can select one or more FortiGate interfaces to use for synchronizing sessions as required for session pickup. Normally session synchronization occurs over the HA heartbeat link. Using this HA option means only the selected interfaces are used for session synchronization and not the HA heartbeat link. If you select more than one interface, session synchronization traffic is load balanced among the selected interfaces.

Moving session synchronization from the HA heartbeat interface reduces the bandwidth required for HA heartbeat traffic and may improve the efficiency and performance of the cluster, especially if the cluster is synchronizing a large number of sessions. Load balancing session synchronization among multiple interfaces can further improve performance and efficiency if the cluster is synchronizing a large number of sessions.

Use the following command to perform cluster session synchronization using the port10 and port12 interfaces.

```
config system ha
    set session-sync-dev port10 port12
end
```

Session synchronization packets use Ethertype 0x8892. The interfaces to use for session synchronization must be connected together either directly using the appropriate cable (possible if there are only two units in the cluster) or using switches. If one of the interfaces becomes disconnected the cluster uses the remaining interfaces for session synchronization. If all of the session synchronization interfaces become disconnected, session synchronization reverts back to using the HA heartbeat link. All session synchronization traffic is between the primary unit and each subordinate unit.

Since large amounts of session synchronization traffic can increase network congestion, it is recommended that you keep this traffic off of your network by using dedicated connections for it.

Note that "unsetting" `session-sync-dev` (i.e. by entering `unset session-sync-dev`) has the following two effects:

1. Session synchronization will use the ports defined as HA heartbeat interfaces (`set hbdev`).
2. Session synchronization packets will be sent over UDP/708 instead of Ethertype 0x8892.

NAT session synchronization

NAT sessions are not synchronized by default. You can enable NAT session synchronization by entering the following command:

```
config system ha
    set session-pickup enable
    set session-pickup-nat enable
end
```

Note that, after a failover with this configuration, all sessions that include the IP addresses of interfaces on the failed FortiGate unit will have nowhere to go since the IP addresses of the failed FortiGate unit will no longer be on the network. If you want NAT sessions to resume after a failover you should not configure NAT to use the destination interface IP address, since the FGSP FortiGate units have different IP addresses. To avoid this issue, you should use IP pools with the type set to `overload` (which is the default IP pool type), as shown in the example below:

```
config firewall ippool
    edit FGSP-pool
        set type overload
        set startip 172.20.120.10
        set endip 172.20.120.20
    end
```

In NAT/Route mode, only sessions for route mode security policies are synchronized. FGSP HA is also available for FortiGate units or virtual domains operating in Transparent mode. Only sessions for normal Transparent mode policies are synchronized.

IPsec tunnel synchronization

When you use the `config system cluster-sync` command to enable FGSP, IPsec keys and other runtime data are synchronized between cluster units. This means that if one of the cluster units goes down the cluster unit that is still operating can quickly get IPsec tunnels re-established without re-negotiating them. However, after a failover, all existing tunnel sessions on the failed FortiGate have to be restarted on the still operating FortiGate.

IPsec tunnel sync only supports dialup IPsec. The interfaces on both FortiGates that are tunnel endpoints must have the same IP addresses and external routers must be configured to load balance IPsec tunnel sessions to the FortiGates in the cluster.

Standalone configuration synchronization uses a very similar process as FGCP. There is a similar relationship between the two FortiGates but only in regards to configuration synchronization, not session information. The primary unit is selected by using priority/override. The heartbeat is used to check the primary unit's health. Once heartbeat loss is detected, a new primary unit is selected.

Automatic session synchronization after peer reboot

The following command allows you to configure an automatic session synchronization after a peer FGSP unit has rebooted. FGSP will send out heartbeat signals (every 1 - 10 seconds, as shown below) if one FortiGate is rebooting and the other FortiGate fails.

To configure automatic session synchronization:

```
config system session-sync
  edit 1
    set down-intfs-before-sess-sync <interfaces> - List of interfaces to be turned down before session
      synchronization is complete.
    set-hb-interval <integer> - (1 - 10 seconds)
    set hb-lost-threshold <integer> - (1 - 10)
  next
end
```

FGFM - FortiGate to FortiManager Protocol

The FortiGate to FortiManager (FGFM) protocol is designed for FortiGate and FortiManager deployment scenarios, especially where NAT is used. These scenarios include the FortiManager on public internet while the FortiGate unit is behind NAT, FortiGate unit is on public internet while FortiManager is behind NAT, or both FortiManager and FortiGate unit have routable IP addresses.

The FortiManager unit's Device Manager uses FGFM to create new device groups, provision and add devices, and install policy packages and device settings.

Port 541 is the default port used for FortiManager traffic on the internal management network.

Adding a FortiGate to the FortiManager

Adding a FortiGate unit to a FortiManager requires configuration on both devices. This section describes the basics to configure management using a FortiManager device.

FortiGate configuration

Adding a FortiGate unit to FortiManager will ensure that the unit will be able to receive antivirus and IPS updates and allow remote management through the FortiManager system, or FortiCloud service. The FortiGate unit can be in either NAT or transparent mode. The FortiManager unit provides remote management of a FortiGate unit over TCP port 541.

You must first enable **Central Management** on the FortiGate so management updates to firmware and FortiGuard services are available:

1. Go to **Security Fabric > Settings**.
2. Enable **Central Management** and set **Type** to **FortiManager**.
3. Enter the FortiManager's **IP/Domain Name** in the field provided.

To configure the previous steps in the CLI, enter the following - note that `fmg` can be set to either an IP address or FQDN:

```
config system central-management
    set fmg <string>
end
```

To use the registration password, enter the following:

```
execute central-mgmt register-device <fmg-serial-no> <fmg-register-password> <fgtusrname>
    <fgt-password>
```

FGFM is also used in ADOMs (Administrative Domains) set to Normal Mode. Normal Mode has Read/Write privileges, where the administrator is able to make changes to the ADOM and manage devices from the FortiManager. FortiGate units in the ADOM will query their own configuration every five seconds. If there has been a configuration change, the FortiGate unit will send a revision on the change to the FortiManager using the FGFM protocol.

To configure central management on the FortiGate unit, enter the following on the FortiGate:

```
config system central-management
    set mode normal
    set fortimanager-fds-override enable
    set fmg <string>
```

end

Configuring an SSL connection

The default encryption automatically sets high and medium encryption algorithms. Algorithms used for **High**, **Medium**, and **Low** follow the openssl definitions below:

Encryption level	Key strength	Algorithms used
High	Key lengths larger than 128 bits, and some cipher suites with 128-bit keys.	DHE-RSA-AES256-SHA:AES256-SHA: EDH-RSA-DES-CBC3-SHA: DES-CBC3-SHA:DES-CBC3-MD5:DHE-RSA-AES128-SHA:AES128-SHA
Medium	Key strengths of 128 bit encryption.	RC4-SHA:RC4-MD5:RC4-MD
Low	Key strengths of 64 or 56 bit encryption algorithms but excluding export cipher suites.	EDH-RSA-DES-CBC-SHA; DES-CBC-SHA; DES-CBC-MD5

An SSL connection can be configured between the two devices and an encryption level selected. To configure the connection in the CLI, enter the following:

```
config system central-management
  set status enable
  set enc-algorithm (default | high | low)
end
```

Note that `default` automatically sets high and medium encryption algorithms.

FortiManager configuration

Use the **Device Manager** pane to add, configure, and manage devices.

You can add existing operational devices, unregistered devices, provision new devices, and add multiple devices at a time.

Adding an operating FortiGate HA cluster to the **Device Manager** pane is similar to adding a standalone device. Type the IP address of the master device. The FortiManager will handle the cluster as a single managed device.

To confirm that a device model or firmware version is supported by current firmware version running on FortiManager, enter the following CLI command:

```
diagnose dvm supported-platforms list
```

See the [FortiManager Administration Guide](#) for full details on adding devices, under **Device Manager**.

Replacing a FortiGate in a FortiManager configuration

FGFM can be used in order to re-establish a connection between a FortiGate unit and a FortiManager configuration. This is useful for if you need a FortiGate unit replaced following an RMA hardware replacement. This applies to a FortiGate running in HA as the primary units; it does not apply to subordinate units.

When the FortiGate unit is replaced, perform a Device Manager Connectivity check or Refresh on the FortiManager to establish the FGFM management tunnel to the FortiGate. If it fails to establish, you can force the tunnel by executing the following command on the FortiManager:

```
execute fgfm reclaim-dev-tunnel <device_name>
```

Debugging FGFM on FortiManager

- To display diagnostic information for troubleshooting, set the debug level of the FGFM daemon (enter a device name to only show messages related to that device):

```
diagnose debug application fgfmsd <integer> <device_name>
```

- To view installation session, object, and session lists:

```
diagnose fgfm install-session
diagnose fgfm object-list
diagnose fgfm session-list <device_ID>
```

- To reclaim a management tunnel (device name is optional):

```
execute fgfm reclaim-dev-tunnel <device_name>
```

- To view the link-local address assigned to the FortiManager:

```
diagnose fmnetwork interface list
```

Debugging FGFM on FortiGate

- To view information about the Central Management System configuration:

```
get system central-management
```

- To produce realtime debugging information:

```
diagnose debug application fgfmd -1
```

- To view the link-local address assigned to the FortiManager:

```
diagnose fmnetwork interface list
```

FortiOS DHCP options and auto DNS hostname for FortiManager details

A diagnose command can be used to show the FortiManager autodiscovery status for the secure sending of FortiManager details to FortiGate.

FortiGate is occasionally required in large deployments where a Zero Touch Provisioning (ZTP) of the unit is required.

Rather than using the CLI Console to configure system settings one at a time, ZTP can help to reduce errors, save time in automated device configuration, and enhance scalability.

This functionality is designed to work even in a closed network with no Internet access.

To verify the FortiManager autodiscovery status, use the following command:

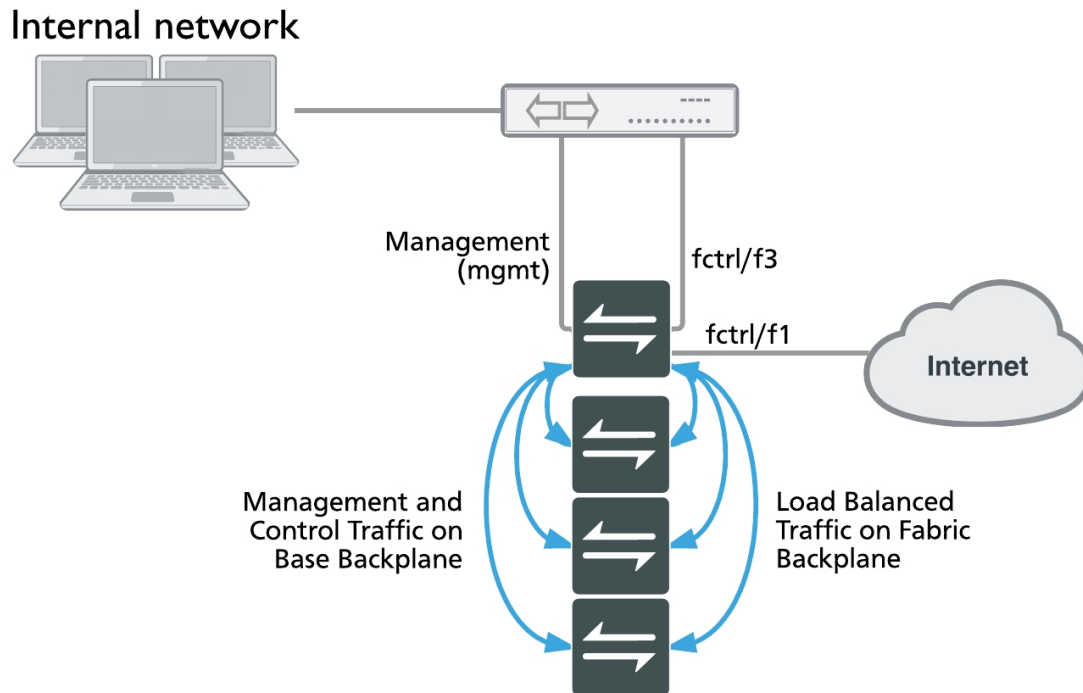

```
diagnose fdsm fmg-auto-discovery-status
```

SLBC - Session-aware Load Balancing Cluster

The Session-aware Load Balancing Cluster (SLBC) protocol is used for clusters consisting of FortiControllers that perform load balancing of both TCP and UDP sessions. As session-aware load balancers, FortiControllers, with FortiASIC DP processors, are capable of directing any TCP or UDP session to any worker installed in the same chassis. It also means that more complex networking features such as NAT, fragmented packets, complex UDP protocols and others such as Session Initiation Protocol (SIP), a communications protocol for signaling and controlling multimedia communication sessions, can be load balanced by the cluster.

Currently, only three FortiController models are available for SLBC: FortiController-5103B, FortiController-5903C, and FortiController-5913C. Supported workers include the FortiGate-5001B, 5001C, 5101C, and 5001D.

FortiGate-7000 series products also support SLBC.

You cannot mix FGCP and SLBC clusters in the same chassis.

An SLBC with two FortiControllers can operate in active-passive mode or dual mode. In active-passive mode, if the active FortiController fails, traffic is transferred to the backup FortiController. In dual mode both FortiControllers load balance traffic and twice as many network interfaces are available.

SLBC clusters consisting of more than one FortiController use the following types of communication between FortiControllers to operate normally:

- **Heartbeat:** Allows the FortiControllers in the cluster to find each other and share status information. If a FortiController stops sending heartbeat packets it is considered down by other cluster members. By default heartbeat traffic uses VLAN 999.
- **Base control:** Communication between FortiControllers on subnet 10.101.11.0/255.255.255.0 using VLAN 301.
- **Base management:** Communication between FortiControllers on subnet 10.101.10.0/255.255.255.0 using VLAN 101.
- **Session synchronization:** If one FortiController fails, session synchronization allows another to take its place and maintain active communication sessions. FortiController-5103B session sync traffic uses VLAN 2000. FortiController-5903C and FortiController-5913C session sync traffic between the FortiControllers in slot 1 uses VLAN 1900 and between the FortiControllers in slot 2 uses VLAN 1901. You cannot change these VLANs.

Note that SLBC does not support session synchronization between workers in the same chassis. The FortiControllers in a cluster keep track of the status of the workers in their chassis and load balance sessions to the workers. If a worker fails the FortiController detects the failure and stops load balancing sessions to that worker. The sessions that the worker is processing when it fails are lost.

Changing the heartbeat VLAN

To change the VLAN from the FortiController GUI, from the **System Information** dashboard widget, beside **HA Status**, select **Configure**. Change the **VLAN to use for HA heartbeat traffic(1-4094)** setting.

You can also change the heartbeat VLAN ID from the FortiController CLI. For example, to change the heartbeat VLAN ID to **333**, enter the following:

```
config system ha
    set hbdev-vlan-id 333
end
```

Setting the mgmt interface as a heartbeat interface

To add the mgmt interface to the list of heartbeat interfaces used, on the FortiController-5103B, enter the following:

```
config system ha
    set hbdev b1 b2 mgmt
end
```

This example adds the mgmt interface for heartbeats to the B1 and B2 interfaces. The B1 and B2 ports are recommended because they are 10G ports and the mgmt interface is a 100Mbit interface.

FortiController-5103B is currently the only model that allows its mgmt interface to be added to the heartbeat interfaces list.

Changing the heartbeat interface mode

By default, only the first heartbeat interface (usually B1) is used for heartbeat traffic. If this interface fails on any of the FortiControllers in a cluster, then the second heartbeat interface is used (B2).

To simultaneously use all heartbeat interfaces for heartbeat traffic, enter the following command:

```
config load-balance-setting
    set base-mgmt-interface-mode active-active
end
```

Changing the base control subnet and VLAN

You can change the base control subnet and VLAN from the FortiController CLI. For example, to change the base control subnet to **10.122.11.0/255.255.255.0** and the VLAN ID to **320**, enter the following:

```
config load-balance setting
  set base-ctrl-network 10.122.11.0 255.255.255.0
  config base-ctrl-interfaces
    edit b1
      set vlan-id 320
    next
    edit b2
      set vlan-id 320
  end
```

Changing the base management subnet and VLAN

You can change the base management subnet from the FortiController GUI under **Load Balance > Config** and changing the **Internal Management Network**.

You can also change the base management subnet and VLAN ID from the FortiController CLI. For example, to change the base management subnet to **10.121.10.0/255.255.255.0** and the VLAN to **131**, enter the following:

```
config load-balance setting
  set base-mgmt-internal-network 10.121.10.0 255.255.255.0
  config base-mgt-interfaces
    edit b1
      set vlan-id 131
    next
    edit b2
      set vlan-id 131
  end
```

If required, you can use different VLAN IDs for the B1 and B2 interface.

Changing this VLAN only changes the VLAN used for base management traffic between chassis. Within a chassis the default VLAN is used.

Enabling and configuring the session sync interface

To enable session synchronization in a two chassis configuration, enter the following command:

```
config load-balance setting
  set session-sync enable
end
```

You will then need to select the interface to use for session sync traffic. The following example sets the FortiController-5103B session sync interface to **F4**:

```
config system ha
  set session-sync-port f4
end
```

The FortiController-5903C and FortiController-5913C use B1 and B2 as the session sync interfaces so no configuration changes are required.

FGCP to SLBC migration

You can convert an FGCP virtual cluster (with VDOMs) to an SLBC cluster. The conversion involves replicating the VDOM, interface, and VLAN configuration of the FGCP cluster on the SLBC cluster primary worker, then backing up the configuration of each FGCP cluster VDOM. Each of the VDOM configuration files is manually edited to adjust interface names. These modified VDOM configuration files are then restored to the corresponding SLBC cluster primary worker VDOMs.

For this migration to work, the FGCP cluster and the SLBC workers must be running the same firmware version, the VDOMs are enabled on the FGCP cluster, and the SLBC workers have been registered and licensed. However, the FGCP cluster units do not have to be the same model as the SLBC cluster workers.

Only VDOM configurations are migrated. You have to manually configure primary worker management and global settings.

Conversion steps

1. Add VDOM(s) to the SLBC primary worker with names that match those of the FGCP cluster.
2. Map FGCP cluster interface names to SLBC primary worker interface names. For example, you can map the FGCP cluster port1 and port2 interfaces to the SLBC primary worker fctl/f1 and fctl/f2 interfaces. You can also map FGCP cluster interfaces to SLBC trunks, and include aggregate interfaces.
3. Add interfaces to the SLBC primary worker VDOMs according to your mapping. This includes moving SLBC physical interfaces into the appropriate VDOMs, creating aggregate interfaces, and creating SLBC trunks if required.
4. Add VLANs to the SLBC primary worker that match VLANs in the FGCP cluster. They should have the same names as the FGCP VLANs, be added to the corresponding SLBC VDOMs and interfaces, and have the same VLAN IDs.
5. Add inter-VDOM links to the SLBC primary worker that match the FGCP cluster.
6. Backup the configurations of each FGCP cluster VDOM, and SLBC primary worker VDOM.
7. Use a text editor to replace the first four lines of each FGCP cluster VDOM configuration file with the first four lines of the corresponding SLBC primary worker VDOM configuration file. Here are example lines from an SLBC primary worker VDOM configuration file:

```
#config-version=FG-5KB-5.02-FW-build670-150318:opmode=0:vdom=1:user=admin
#conf_file_ver=2306222306838080295
#buildno=0670
#global_vdom=0:vd_name=VDOM1
```
8. With the text editor, edit each FGCP cluster VDOM configuration file and replace all FGCP cluster interface names with the corresponding SLBC worker interface names, according to the mapping you created in step 2.
9. Set up a console connection to the SLBC primary worker to check for errors during the following steps.
10. From the SLBC primary worker, restore each FGCP cluster VDOM configuration file to each corresponding SLBC primary worker VDOM.
11. Check the following on the SLBC primary worker:
 - Make sure `set type fctrl-trunk` is enabled for SLBC trunk interfaces.
 - Enable the global and management VDOM features that you need, including SNMP, logging, connections to FortiManager, FortiAnalyzer, and so on.
 - If there is a FortiController in chassis slot 2, make sure the worker base2 interface status is up.
 - Remove `snmp-index` entries for each interface.

- Since you can manage the workers from the FortiController you can remove management-related configurations using the worker mgmt1 and mgmt2 interfaces (Logging, SNMP, admin access, etc.) if you are not going to use these interfaces for management.

How to set up SLBC with one FortiController-5103B

This example describes the basics of setting up a Session-aware Load Balancing Cluster (SLBC) that consists of one FortiController-5103B, installed in chassis slot 1, and three FortiGate-5001C workers, installed in chassis slots 3, 4, and 5.

This SLBC configuration can have up to eight 10Gbit network connections.

Configuring the hardware

1. Install a FortiGate-5000 series chassis and connect it to power. Install the FortiController in slot 1. Install the workers in slots 3, 4, and 5. Power on the chassis.
2. Check the chassis, FortiController, and FortiGate LEDs to verify that all components are operating normally. (To check normal operation LED status see the FortiGate-5000 series documents available [here](#).)
3. Check the FortiSwitch-ATCA release notes and install the latest supported firmware on the FortiController and on the workers. Get FortiController firmware from the [Fortinet Support site](#). Select the FortiSwitch-ATCA product.

Configuring the FortiController

To configure the FortiController, you will need to either connect to the FortiController GUI or CLI with the default IP address of `http://192.168.1.99`. Log in using the admin account (no password).

1. Add a password for the admin account. Use the **Administrators** widget in the GUI, or enter the following CLI command:

```
config admin user
  edit admin
    set password <password>
  end
```
2. Change the FortiController mgmt interface IP address. Use the **Management Port** widget in the GUI, or enter the following CLI command:

```
config system interface
  edit mgmt
    set ip 172.20.120.151/24
  end
```
3. If you need to add a default route for the management IP address, enter the following command:

```
config route static
  edit route 1
    set gateway 172.20.121.2
  end
```
4. To set the chassis type that you are using, enter the following CLI command:

```
config system global
  set chassis-type fortigate-5140
end
```
5. Go to **Load Balance > Config** and add workers to the cluster by selecting **Edit** and moving the slots that contain workers to the **Member** list. The Config page shows the slots in which the cluster expects to find workers. Since the workers have not been configured yet, their status is **Down**.
Configure the **External Management IP/Netmask**. Once the workers are connected to the cluster, you can use

this IP address to manage and configure them.

6. You can also enter the following CLI command to add slots 3, 4, and 5 to the cluster:

```
config load-balance setting
  config slots
    edit 3
  next
  edit 4
  next
  edit 5
  end
end
```

7. You can also enter the following command to configure the external management IP/Netmask and management access to the following address:

```
config load-balance setting
  set base-mgmt-external-ip 172.20.120.100 255.255.255.0
  set base-mgmt-allowaccess https ssh ping
end
```

Adding the workers

Before you begin adding workers to the cluster, make sure you enter the `execute factoryreset` command in the CLI so the workers are set to factory default settings. If the workers are going to run FortiOS Carrier, add the FortiOS Carrier licence instead - this will reset the worker to factory default settings.

Also make sure to register and apply licenses to each worker, including FortiClient licensing, FortiCloud activation, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMs). You can also install any third-party certificates on the primary worker before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to all of the workers. FortiToken licenses can be added at any time, which will also synchronize across all of the workers.

1. Log in to each of the worker's CLI and enter the following CLI command to set the worker to operate in FortiController mode:

```
config system elbc
  set mode fortincontroller
end
```

Once the command is entered, the worker restarts and joins the cluster.

2. On the FortiController, go to **Load Balance > Status**. You will see the workers appear in their appropriate slots. The worker in the lowest slot number usually becomes the primary unit.

You can now manage the workers in the same way as you would manage a standalone FortiGate. You can connect to the worker GUI or CLI using the **External Management IP**. If you had configured the worker mgmt1 or mgmt2 interfaces you can also connect to one of these addresses to manage the cluster.

To operate the cluster, connect networks to the FortiController front panel interfaces and connect to a worker GUI or CLI to configure the workers to process the traffic they receive. When you connect to the External Management IP you connect to the primary worker. When you make configuration changes they are synchronized to all workers in the cluster.

Managing the devices in an SLBC with the external management IP

The External Management IP address is used to manage all of the individual devices in a SLBC by adding a special port number. This special port number begins with the standard port number for the protocol you are using

and is followed by two digits that identify the chassis number and slot number. The port number can be calculated using the following formula:

$$\text{service_port} \times 100 + (\text{chassis_id} - 1) \times 20 + \text{slot_id}$$

Where:

- **service_port** is the normal port number for the management service (80 for HTTP, 443 for HTTPS and so on).
- **chassis_id** is the chassis ID specified as part of the FortiController HA configuration and can be 1 or 2.
- **slot_id** is the number of the chassis slot.

By default, chassis 1 is the primary chassis and chassis 2 is the backup chassis. However, the actual primary chassis is the one with the primary FortiController, which can be changed independently of the chassis number. Additionally, the **chassis_id** is defined by the chassis number, *not* whether the chassis contains the primary FortiController.

Some examples:

- HTTPS, chassis 1, slot 2: $443 \times 100 + (1 - 1) \times 20 + 2 = 44300 + 0 + 2 = 44302$:
browse to: <https://172.20.120.100:44302>
- HTTP, chassis 2, slot 4: $80 \times 100 + (2 - 1) \times 20 + 4 = 8000 + 20 + 4 = 8024$:
browse to <http://172.20.120.100/8024>
- HTTPS, chassis 1, slot 10: $443 \times 100 + (1 - 1) \times 20 + 10 = 44300 + 0 + 10 = 44310$:
browse to <https://172.20.120.100/44310>

Single chassis or chassis 1 special management port numbers

Slot number	HTTP (80)	HTTPS (443)	Telnet (23)	SSH (22)	SNMP (161)
Slot 1	8001	44301	2301	2201	16101
Slot 2	8002	44302	2302	2202	16102
Slot 3	8003	44303	2303	2203	16103
Slot 4	8004	44304	2304	2204	16104
Slot 5	8005	44305	2305	2205	16105
Slot 6	8006	44306	2306	2206	16106
Slot 7	8007	44307	2307	2207	16107
Slot 8	8008	44308	2308	2208	16108
Slot 9	8009	44309	2309	2209	16109

Slot number	HTTP (80)	HTTPS (443)	Telnet (23)	SSH (22)	SNMP (161)
Slot 10	8010	44310	2310	2210	16110
Slot 11	8011	44311	2311	2211	16111
Slot 12	8012	44312	2312	2212	16112
Slot 13	8013	44313	2313	2213	16113
Slot 14	8014	44314	2314	2214	16114

Chassis 2 special management port numbers

Slot number	HTTP (80)	HTTPS (443)	Telnet (23)	SSH (22)	SNMP (161)
Slot 1	8021	44321	2321	2221	16121
Slot 2	8022	44322	2322	2222	16122
Slot 3	8023	44323	2323	2223	16123
Slot 4	8024	44324	2324	2224	16124
Slot 5	8025	44325	2325	2225	16125
Slot 6	8026	44326	2326	2226	16126
Slot 7	8027	44327	2327	2227	16127
Slot 8	8028	44328	2328	2228	16128
Slot 9	8029	44329	2329	2229	16129
Slot 10	8030	44330	2330	2230	16130
Slot 11	8031	44331	2331	2231	16131
Slot 12	8032	44332	2332	2232	16132
Slot 13	8033	44333	2333	2233	16133
Slot 14	8034	44334	2334	2234	16134

For more detailed information regarding FortiController SLBC configurations, see the [FortiController Session-Aware Load Balancing \(SLBC\) Guide](#).

Fortinet Security Fabric

The Fortinet Security Fabric spans across an entire network linking different security sensors and tools together to collect, coordinate, and respond to malicious behavior in real time. Security Fabric can be used to coordinate the behavior of different Fortinet products in your network, including FortiGate, FortiAnalyzer, FortiClient, FortiSandbox, FortiAP, FortiSwitch, and FortiClient Enterprise Management Server (EMS). Security Fabric supports FortiOS 5.4.1+, FortiSwitchOS 3.3+, and FortiClient 5.4.1+.

Port TCP/8009 is the port FortiGate uses for incoming traffic from the FortiClient Portal, as user information (such as IP address, MAC address, avatar, and other profile information) is automatically synchronized to the FortiGate and EMS.

The brief example below assumes that FortiTelemetry has been enabled on the top-level FortiGate (**FGT1**), OSPF routing has been configured, and that policies have been created for all FortiGate units to access the Internet.

For more details on how to configure a security fabric between FortiGate units, see [Fortinet Security Fabric installation](#) on the Fortinet Cookbook website.

Enabling Security Fabric on the FortiGate:

1. On the upstream FortiGate (FGT1), go to **Security Fabric > Settings** and enable **FortiGate Telemetry**.
2. Enter a **Group name** and **Group password** for the fabric.

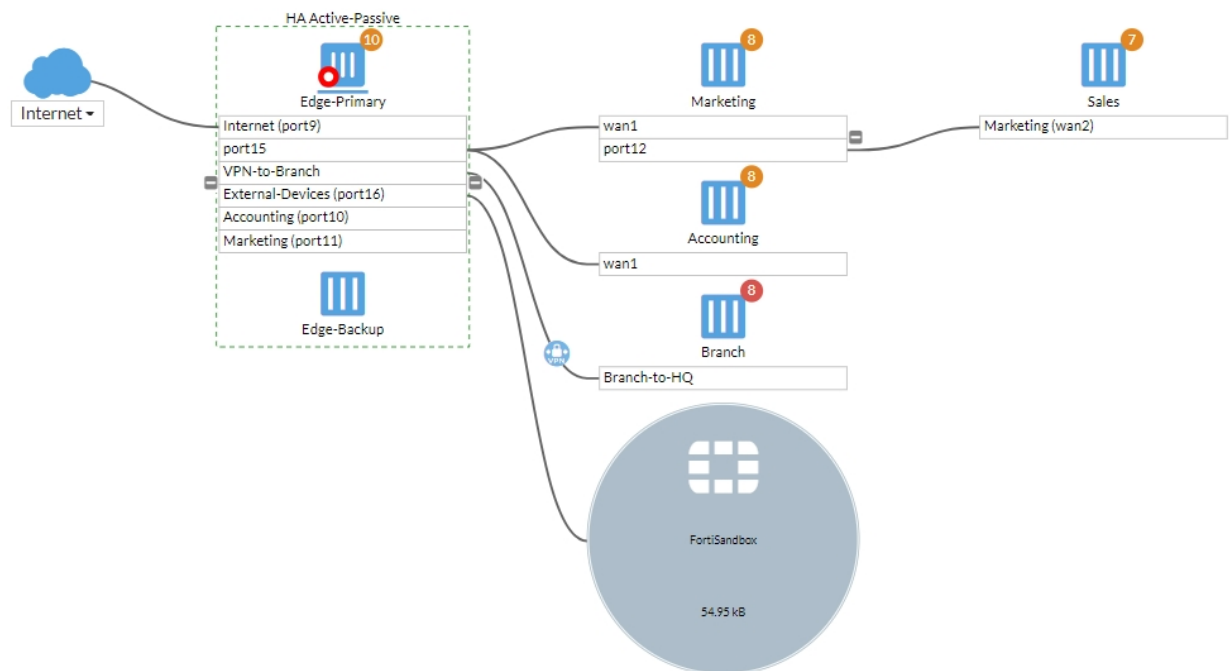

3. On a downstream FortiGate (such as FGT2 or FGT3), configure the same fabric settings as were set on FGT1.
4. Enable **Connect to upstream FortiGate**.
Be sure you do *not* enable this on the topmost-level FortiGate (in this example, FGT1).
5. In **FortiGate IP**, enter the FGT1 interface that has **FortiTelemetry** enabled. The **Management IP** can be left to use the WAN IP or optionally specified.

Once set up, you can view your network's Security Fabric configuration under **Security Fabric** through two topology dashboards.

6. On the top-level FortiGate, go to **Security Fabric > Physical Topology**. This dashboard shows a visualization of all access layer devices in the fabric.

7. Go to **Security Fabric > Logical Topology** to view information about the interfaces (logical or physical) that each device in the fabric is connected to.

Other Security Fabric configurations for your network are available through the Fortinet Cookbook [Security Fabric Collection](#) page.

FortiTelemetry/On-Net/FortiClient Endpoint Compliance

FortiTelemetry (called FortiHeartBeat in FortiOS 5.4.0 and FortiClient Access in FortiOS 5.2) is an interface option that listens for connections from devices with FortiClient installed.

FortiTelemetry is the TCP/8013 protocol used between FortiClient and FortiGate, FortiClient and FortiClient EMS, and between FortiGate and other FortiGates in CSF configurations.

While all GUI references of FortiHeartBeat have been changed to FortiTelemetry in FortiOS 5.4.1, the CLI options have *not* been renamed and will remain as `fortiheartbeat`.

With FortiTelemetry enabled on the FortiGate, you can enforce FortiTelemetry for all FortiClients. This FortiClient endpoint compliance will require all clients to have FortiClient installed in order to get access through the FortiGate. Configure these settings in the internal interface under **Network > Interfaces**. Edit the interface of your choice. Under **Administrative Access**, enable **FortiTelemetry**, then enable **FortiClient On-Net Status**.

To enable FortiTelemetry on an interface - CLI:

```
config system interface edit <port_number>
    set listen-forticlient-connection enable
    set endpoint-compliance enable
end
```

You can also enable **DHCP server** and **FortiClient On-Net Status** to display the on-net status of FortiClient devices on the FortiClient Monitor (under **Monitor > FortiClient Monitor**).

To enable FortiClient On-Net status for a DHCP server added to the port1 interface - CLI:

```
config system dhcp server edit 1
    set interface port1
    set forticlient-on-net-status enable
end
```

FortiClient endpoint licence updates

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum (forum.fortinet.com). Phone support is only available for paid licenses.

Model(s)	Maximum Client Limit
VM00	200
FGT/FWF 30 to 90 series	200
FGT 100 to 400 series	600
FGT 500 to 900 series, VM01, VM02	2,000
FGT 1000 to 2900 series	20,000
FGT 3000 to 3600 series, VM04	50,000
FGT 3700D and above, VM08 and above	100,000

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

Connecting FortiClient Telemetry after installation

After FortiClient is installed on an endpoint, FortiClient automatically launches and searches for a FortiGate or FortiClient EMS for FortiClient Telemetry connection. When FortiClient locates a FortiGate or EMS, the **FortiGate Detected** or **Enterprise Management Server (EMS) Detected** dialog box will appear:

If all the information displayed is correct, select **Accept**. FortiClient Telemetry will connect to the identified FortiGate/EMS.

Alternately, you can select **Cancel** and launch FortiClient without connecting to FortiClient Telemetry. This will launch FortiClient in standalone mode, where you can manually connect FortiClient Telemetry.

After FortiClient Telemetry is connected to FortiGate or EMS, FortiClient downloads a profile from FortiGate/EMS.

How FortiClient locates FortiGate/EMS

FortiClient uses the following methods in the following order to automatically locate FortiGate/EMS for Telemetry connection:

- 1. Telemetry gateway IP list:** FortiClient Telemetry searches for IP addresses in its subnet in the Gateway IP list. It connects to the FortiGate in the list that is also in the same subnet as the host system.
If FortiClient cannot find any FortiGates in its subnet, it will attempt to connect to the first reachable FortiGate in the list, starting from the top. The order of the list is maintained as it was configured in the Gateway IP list.
- 2. Remembered gateway IP list:** You can configure FortiClient to remember gateway IP addresses when you connect Telemetry to FortiGate/EMS. Later FortiClient can use the remembered IP addresses to automatically connect Telemetry to FortiGate/EMS.
- 3. Default gateway IP address:** The default gateway IP address is specified on the FortiClient endpoint and is used to automatically connect to FortiGate. This method does not support connection to EMS.

FortiClient obtains the default gateway IP address from the operating system on the endpoint device. The default gateway IP address of the endpoint device should be the IP address for the FortiGate interface with Telemetry enabled.

If FortiClient is unable to automatically locate a FortiGate/EMS on the network for Telemetry connection, you can type the gateway IP address of the FortiGate/EMS.

FortiClient uses the same process to connect Telemetry to FortiGate/EMS after the FortiClient endpoint reboots, rejoins the network, or encounters a network change.

FortiGuard

FortiGuard services can be purchased and registered to your FortiGate unit. The FortiGate must be connected to the Internet in order to automatically connect to the FortiGuard Distribution Network (FDN) to validate the license and download FDN updates.

The FortiGuard subscription update services include:

- AntiVirus (AV)
- Intrusion Protection Service (IPS)
- Application Control
- Anti-Spam
- Web Filtering
- Web Application Firewall (WAF)

The FDN sends notice that a FortiGuard AntiVirus and IPS update is available on UDP/9443.

The following information concerns certain considerations in regards to FortiGate receiving FortiGuard updates through FDN, how the submission of malware statistics to FortiGuard is handled, an automatic update behaviour when FortiGate has expired licenses, and related CLI commands.

Enabling FDN updates and FortiGuard services

In order to receive FortiGuard subscription updates, the unit needs to have access to the Internet and be able to connect to a DNS server in order to resolve the following URLs:

- **update.fortiguard.net:** For AV and IPS updates.
 - **service.fortiguard.net:** For web filtering and anti-spam updates.
1. Go to **System > FortiGuard**. Under **AntiVirus & IPS Updates**, enable **Scheduled Updates**, and configure an update schedule.
 2. You can force the unit to connect to the AV/IPS server by selecting **Update AV & IPS Definitions**.
 3. You can view your subscription details above in the **License Information** table.
 4. Once the schedule has been enabled, select **Apply**.

To see if the service is viable, open the CLI console and enter the following commands below.

For Web Filtering:

```
diagnose debug rating
```

For Anti-Spam:

```
diagnose spamfilter fortishield servers
```

If only one or two IPs are displayed in the command outputs, it could be one of the following issues:

- **No response from the DNS server:** Either the DNS server is unreachable or there is a problem with the routing. Make sure that contact to the DNS server is available by resolving some URLs from the CLI, for example:

```
execute ping www.google.com
execute ping service.fortiguard.net
```

You can also

- **Review update errors:** Review update information from the last update, enable debug outputs and force the update:

```
diagnose test update info
diagnose debug enable
diagnose debug application update 255
execute update-ase
execute update-av
execute update-ips
```

After troubleshooting, it is highly recommended to turn off debug mode:

```
diagnose debug disable
diagnose debug application update 0
```

- **FortiGuard Web filtering:** Port blocking or packet inspection is occurring downstream. The default port used by the FortiGuard for the FortiGuard services is 8888.

You can change this port using the following command:

```
config system fortiguard
    set port <port_number>
end
```

You can also change the source port for management traffic with the following CLI command:

```
config system global
    set ip-src-port-range 1035-25000
end
diagnose test application urlfilter 99
diagnose test application smtp 99
```

Submission of malware statistics to FortiGuard

FortiGates periodically send encrypted AntiVirus, IPS, botnet IP list, and Application Control event statistics to FortiGuard. Included with these malware statistics is the IP address and serial number of the FortiGate and the country in which the FortiGate is located.

The statistics are used to improve various aspects of FortiGate malware protection. For example, AntiVirus statistics allow FortiGuard to determine the viruses that are active in the wild. Signatures for such viruses are kept in the Active AV Signature Database that is used by many Fortinet products. Signatures for inactive viruses are moved to the Extended/Extreme AV Signature Database used by some customers. If the events for inactive viruses start appearing in malware statistics, these signatures can be moved back to the Active AV Signature Database.

The FortiGate and FortiGuard servers go through a 2-way SSL/TLS 1.2 authentication before any data is transmitted. The certificates used in this process must be trusted by each other and signed by Fortinet CA server.

Malware statistics are accumulated and sent periodically (by default every 60 minutes).

Fortinet products can only accept data from authorized FortiGuard servers. Fortinet products use DNS to find FortiGuard servers and periodically update their FortiGate server list. All other servers are provided by a list that is updated through the encrypted channel.

The submission of malware data is in accordance with Fortinet's "Automatically-Collected Information" detailed in the [Fortinet Privacy Policy](#), and the purpose of this collection is outlined in the "Use of your Information" section of the privacy policy.

There is no sensitive or personal information included in these submissions. Only malware statistics are sent.

Fortinet uses the malware statistics collected in this manner to improve the performance of the FortiGate services and to display statistics on the [Fortinet Support](#) website for customers registered FortiGate devices.

Fortinet may also publish or share statistics or results derived from this malware data with various audiences. The malware statistics shared in this way do not include any customer data.

To enable, disable, and/or customize how often statistics are sent to FortiGuard, use the following command:

CLI syntax

```
config system global
  set fds-statistics {enable | disable}
  set fds-statistics-period <minutes>
end
```

In addition to secure submission of statistics to FortiGuard, there are other mechanisms in place to prevent unauthorized FortiGuard updates from clients:

- The server certificate has to be authenticated by FortiGates, and it only trusts Fortinet's root certificate.
- Proprietary encryption (including FGCP, an application-level proprietary protocol) that only Fortinet's own servers/devices can prepare.

FortiGates can only accept data from Fortinet's own list of servers, although the list can be updated through previously connected servers. DNS is used on the initial server, but all other servers are provided by a list that is updated through SSL, meaning that only FortiGates accept data from those servers.

Automatic update at every GUI login

FortiGates running FortiOS 5.6.1 and above may perform automatic "update now" updates when one of the "core" licenses is unavailable: Application Control, IPS, or AntiVirus. Please note that this automatic update is triggered even if the following CLI command is set:

```
config system autoupdate schedule
  set status disable
end
```

CLI Syntax

The following section contains commands to control FortiGuard.

system autoupdate push-update

The following command will set the FDN push update port.

```
config system.autoupdate push-update
  set port <integer>
end
```

system autoupdate tunneling

The following command will set the proxy server port that the FortiGate will use to connect to the FortiGuard Distribution Network (FDN).

```
config system.autoupdate tunneling
    set port <integer>
end
```

system fortiguard

The following command will set the port by which scheduled FortiGuard service updates will be received.

```
config system fortiguard
    set port {53 | 8888 | 80}
end
```

webfilter fortiguard

The following command will close ports used for HTTPS/HTTP override authentication and disable user overrides:

```
config webfilter fortiguard
    set close-ports {enable | disable}
end
```

For more information, including FortiGuard execute commands used to manage FortiCloud domains and operations, see the [CLI Reference](#).

FortiLink

FortiGate units can be used to remotely manage FortiSwitch units, which is also known as using a FortiSwitch in FortiLink mode. FortiLink defines the management interface and the remote management protocol between the FortiGate and FortiSwitch.

Different FortiGate models support remote management for varying numbers of FortiSwitches, as shown below:

FortiGate	Number of FortiSwitches
Up to FortiGate 98 and FortiGate VM01	8
FortiGate 100 to 280 and FortiGate VM02	24
FortiGate 300 to 5xx	48
FortiGate 600 to 900 and FortiGate VM04	64
FortiGate 1000 and up	128
FortiGate-3000 and up, and FortiGate VM08 and up	300

Supported FortiSwitch models

The following table shows the FortiSwitch models that support FortiLink mode when paired with the corresponding FortiGate models and the listed minimum software releases.

FortiSwitch	FortiGate	Earliest FortiSwitchOS	Earliest FortiOS
FS-224D-POE	FGT-90D (WiFi/POE)	3.0.0	5.2.2
FS-108D-POE	FGT-60D (all)	3.0.1	5.2.3
FSR-112D-POE	FGR-90D	3.0.1	5.2.3
FS-124D	FGT-90D + FGT-60D	3.0.1	5.2.3
FS-124D-POE	FGT-90D + FGT-60D	3.0.1	5.2.3
FS-224D-FPOE	FGT-90D + FGT-60D	3.0.1	5.2.3

Note that **all** FortiSwitches above also support FortiLink mode when paired with the following FortiGate models: 100D, 140D (POE, T1), 200D, 240D, 280D (POE), 600C, 800C, and 1000C.

FortiLink ports for each FortiSwitch model

Each FortiSwitch model provides one designated port for the FortiLink connection. The table below lists the FortiLink port for each model:

FortiSwitch model	Port for FortiLink connection
FS-28C	WAN port 1
FS-324B-POE	Management Port
FS-448B (10G only)	WAN port (uplink 1)
FS-348B	Last port (port 48)
For all D-series switches, use the last (highest number) port for FortiLink. For example:	
FS-108D-POE	Last port (port 10)
FSR-112D-POE	Last port (port 12)
FS-124D	Last port (port 26). May require an SFP module.*
FS-224D-POE	Last port (port 24)
FS-224D-FPOE	Last port (port 28). May require an SFP module.*

* FortiSwitch 3.3.1 and later releases support the use of an RJ-45 port for FortiLink. For additional information, visit the [Fortinet Support](#) website.

FortiLink ports for each FortiGate model

The following table shows the ports for each model of FortiGate that can be FortiLink-dedicated.

FortiGate model	Port for FortiLink connection
FGT-90D, FGT-90D-POE, FWF-90D, FWF-90D-POE	port1 - port14
FGT-60D, FGT-60D-POE, FWF-60D, FWF-60D-POE	port1 - port7
FGT-100D	port1 - port16
FGT-140D, 140D-POE, 140D-POE-T1	port1 - port36
FGT-200D	port1 - port16
FGT-240D	port1 - port40
FGT-280D, FGT-280D-POE	port1 - port84
FGT-600C	port3 - port22

FortiGate model	Port for FortiLink connection
FGT-800C	port3 - port24
FGT-1000C	port3 - port14, port23, port24

Auto-discovery of the FortiSwitch ports

In releases FortiSwitchOS 3.3.0 and beyond, the D-series FortiSwitch models support FortiLink auto-discovery, which is automatic detection of the port connected to the FortiGate.

You can use any of the switch ports for FortiLink. Use the following FortiSwitch CLI commands to configure a port for FortiLink auto-discovery:

```
config switch interface
edit <port>
set auto-discovery-fortilink enable
end
```

Note that some FortiSwitch ports are enabled for auto-discovery by default.

Each FortiSwitch model provides a set of ports that are enabled for FortiLink auto-discovery by default. If you connect the FortiLink using one of these ports, no switch configuration is required.

In general (in FortiSwitchOS 3.4.0 and later releases), the last four ports are the default auto-discovery FortiLink ports. The table below lists the default auto-discovery ports for each switch model:

FortiSwitch model	Default Auto-FortiLink ports
FS-108D	ports 9 and 10
FSR-112D	ports 9, 10, 11, and 12
FS-124D, FS-124D-POE	ports 23, 24, 25, and 26
FS-224D-POE	ports 21, 22, 23, and 24
FS-224D-FPOE	ports 25, 26, 27, and 28
FS-248D-POE	ports 49, 50, 51, and 52
FS-248D-FPOE	ports 49, 50, 51, and 52
FS-424D, FS-424D-POE, FS-424D-FPOE	ports 25 and 26
FS-448D, FS-448D-POE, FS-448D-FPOE	ports 49, 50, 51, and 52
FS-524D, FS-524D-FPOE	ports 25, 26, 27, 28, 29, and 30
FS-548D, FS-548D-FPOE	ports 49, 50, 51, 52, 53, and 54
FS-1024D, FS-1048D, FS-3032D	all ports

You can also run the `show switch interface` CLI command on the FortiSwitch to see the ports that have auto-discovery enabled.

Adding a managed FortiSwitch to the FortiGate

The following steps show how to add a new managed FortiSwitch using the FortiGate GUI or the CLI.

For FortiSwitchOS releases prior to 3.3.0, you must [Set the FortiSwitch to remote management mode](#) before following the steps below.

Using the FortiGate GUI:

1. Connect a cable from the designated FortiSwitch port to an unused port on the FortiGate. Refer to [FortiLink ports for each FortiSwitch model](#) for additional information.
2. Go to **Network > Interfaces** and edit an internal port on the FortiGate.
3. Set **Addressing mode** to **Dedicated to FortiSwitch** and select **OK**.
4. As of FortiOS 5.4.0, the **Managed FortiSwitch** GUI option can only be accessed by enabling it through the CLI console.

Open the CLI console and enter the following command to make the switch controller available in the GUI, and to set the reserved subnetwork for the controller:

```
config system global
    set switch-controller enable
    set switch-controller-reserved-network 169.254.254.0 255.255.255.0
end
```

5. Go to **WiFi & Switch Controller > Managed FortiSwitch**. The new FortiSwitch should now be displayed in the table.
6. Right-click on the FortiSwitch and select **Authorize**.

Using the FortiGate CLI:

Note that, for the example shown below, the FortiGate's port1 is configured as the FortiLink port.

1. If required, remove port1 from the **lan** interface:

```
config system virtual-switch
    edit lan
        config port
            delete port1
        end
    end
end
```

2. Configure the interface for port1:

```
config system interface
    edit port1
        set ip 172.20.120.10 255.255.255.0
        set allowaccess capwap
        set vlanforward enable
    end
end
```

3. Configure an NTP server on port1:

```
config system ntp
```

```
set server-mode enable
set interface port1
end
```

4. Authorize the FortiSwitch unit as a managed switch (note that FortiSwitch will reboot once you issue the command below):

```
config switch-controller managed-switch
edit FS224D3W14000370
set fsw-wan1-admin enable
end
end
```

5. Configure a DHCP server on port1:

```
config system dhcp server
edit 0
set netmask 255.255.255.252
set interface port1
config ip-range
edit 0
set start-ip 169.254.254.2
set end-ip 169.254.254.50
end
set vci-match enable
set vci-string FortiSwitch
set ntp-service local
end
end
```

Set the FortiSwitch to remote management mode

Use the FortiSwitch GUI or the CLI to set the remote management mode.

Note that the following steps are not necessary for FortiSwitchOS releases 3.3.0 or later.

Using the FortiSwitch GUI:

1. Go to **Dashboard > Main > System Information**.
2. Beside **Operation Mode**, select **Change**.
3. Change **Management Mode** to **FortiGate Remote Management** and select **OK**.
4. A warning will appear asking if you wish to continue. Select **OK**.

Using the FortiSwitch CLI:

```
config system global
set switch-mgmt-mode fortilink
end
```

Configuring the FortiSwitch remote management port

If the FortiSwitch model has a dedicated management port, you can configure remote management to the FortiSwitch. In FortiLink mode, the FortiGate is the default gateway, so you need to configure an explicit route for the FortiSwitch management port.

To do this, from the FortiSwitch CLI, enter the following command:

```
config router static
edit 1
```

```
set device mgmt
set gateway <router_IP_address>
set dst <router_subnet> <subnet_mask>
end
end
```

Configuring FortiLink LAG

Starting with FortiOS 5.4.0 and FortiSwitchOS 3.3.0, you can configure the FortiLink as a Link Aggregation Group (LAG) to provide increased bandwidth between the FortiGate and FortiSwitch.

Connect any two ports on the FortiGate to two ports on the FortiSwitch. Make sure that you use the designated FortiLink port as one of the ports on the switch.

To configure the FortiLink as a LAG on the FortiGate, create a trunk (of type `fortilink`) with the two ports that you connected to the switch:

```
config system interface
  edit "fortilink"
    set vdom root
    set allowaccess ping capwap http https
    set type fortilink
    set member port4 port5
    set snmp-index 17
    set lacp-mode static
  next
end
config system ntp
  set ntpsync enable
  set syncinterval 60
  set server-mode enable
  set interface "fortilink"
end
```

There is no specific configuration required for the LAG on the switch.

FortiOS WAN optimization

Organizations with multiple locations or businesses using the cloud can provide license-free WAN optimization using FortiOS.

WAN Optimization is a comprehensive solution that maximizes your WAN performance and provides intelligent bandwidth management and unmatched consolidated security performance. WAN optimization reduces your network overhead and removes unnecessary traffic for a better overall performance experience. Efficient use of bandwidth and better application performance will remove the need for costly WAN link upgrades between data centers and other expensive solutions for your network traffic growth.

WAN optimization is available on FortiGate models with internal storage that also support SSL acceleration. Internal storage includes high-capacity internal hard disks, AMC hard disk modules, FortiGate Storage Modules (FSMs) or over 4 GB of internal flash storage.

WAN optimization tunnels use port 7810.

The following features below are available through WAN optimization:

Protocol optimization

Protocol optimization is effective for applications designed for the LAN that do not function well on low bandwidth, high latency networks. FortiOS protocol optimization improves the efficiency of CIFS, FTP, HTTP, MAPI, and general TCP sessions.

CIFS, for example, requires many background transactions to successfully transfer a single file. When transferring the file, CIFS sends small chunks of data and waits sequentially for each chunk's arrival and acknowledgment before sending the next chunk. This large amount of requests and acknowledgements of traffic can delay transfers. WAN Optimization removes this complexity and improves the efficiency of transferring the file.

TCP protocol optimization uses techniques such as SACK support, window scaling and window size adjustment, and connection pooling to remove common WAN TCP bottlenecks.

Regular bandwidth usage**Improved bandwidth usage with FortiGate protocol optimization****Byte caching**

Byte caching improves caching by accelerating the transfer of similar, but not identical content. Byte caching reduces the amount of data crossing the WAN when multiple different emails with the same or similar attachments or different versions of an attachment are downloaded from a corporate email server to different locations over the WAN.

Byte caching breaks large units of application data, such as email attachments or file downloads, into smaller chunks of data. Each chunk of data is labeled with a hash, and chunks with their respective hashes are stored in a database on the local FortiGate unit. When a remote user requests a file, WAN optimization sends the hashes, rather than the actual data. The FortiGate unit at the other end of the WAN tunnel reassembles the data from its own hash database, only downloading the chunks it is missing. Deduplication, or the process of eliminating duplicate data, will reduce space consumption.

Byte caching is not application specific, and assists by accelerating all protocols supported by WAN optimization.

Web caching

WAN optimization reduces download times of content from central files repositories through web caching. FortiOS Web caching stores remote files and web pages on local FortiGate devices for easy local access to commonly accessed files. There is little impact on the WAN, resulting in reduced latency for those requesting the files.

In addition, web caching also recognizes requests for Windows or MS Office updates, and downloads the new update file in the background. Once downloaded to the cache, the new update file is available to all users, and all subsequent requests for this update are rapidly downloaded from the cache.

Traffic shaping

Controls data flow for specific applications, giving administrators the flexibility to choose which applications take precedence over the WAN. A common use case of traffic shaping would be to prevent one protocol or application from flooding a link over other protocols deemed more important by the administrator.

SSL acceleration

SSL is used by many organizations to keep WAN communications private. WAN Optimization boosts SSL acceleration properties of FortiGate FortiASIC hardware by accelerating SSL traffic across the WAN. The FortiGate unit handles SSL encryption/decryption for corporate servers providing SSL encrypted connections over the WAN.

Explicit web proxy server

Allows users on the internal network to browse the Internet through the explicit web proxy server.

Explicit FTP proxy server

Allows users on the internal network to access FTP servers through the explicit FTP proxy server.

Reverse proxy

The web and FTP proxies can be configured to protect access to web or FTP servers that are behind the FortiGate using a reverse proxy configuration. Reverse proxies retrieve resources on behalf of a client from one or more servers. These resources are then returned to the client as if they originated from the proxy server.

WCCP

The Web Cache Communication Protocol (WCCP) allows you to offload web caching to redundant web caching servers. This traffic redirection helps to improve response time and optimize network resource usage.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended HA configuration for WAN optimization is active-passive mode. Also, when the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions. HA also does not support WAN optimization session failover.

Configuring an explicit proxy with WAN optimization web caching

For this configuration, all devices on the wireless network will be required to connect to the proxy at port 8080 before they can browse the Internet. WAN Optimization web caching is added to reduce the amount of Internet bandwidth used and improve web browsing performance.

Enabling WAN optimization and configuring the explicit web proxy for the wireless interface

1. Go to **System > Feature Visibility**. Ensure that **Explicit Proxy** is enabled.
To make WAN Optimization and Web Caching settings available in the GUI, enter the following CLI command:

```
config system settings
    set gui-wanopt-cache enable
end
```
1. Go to **Network > Interfaces**, edit the wireless interface and select **Enable Explicit Web Proxy**.
2. Go to **Network > Explicit Proxy**. Enable **Explicit Web Proxy**. Make sure that **Default Firewall Policy Action** is set to **Deny**.

Adding an explicit web proxy policy

1. Go to **Policy & Objects > Proxy Policy** and create a new policy.
2. Set **Proxy Type** to **Explicit Web**, the **Outgoing Interface** to the Internet-facing interface, and the remaining fields as required.

For more detailed information, see [General web proxy configuration steps](#).

Configuring devices on the wireless network to use the web proxy

To use the web proxy, all devices on the wireless network must be configured to use the explicit proxy server. The IP address of the server is the IP address of the FortiGate's wireless interface (for example, 10.10.80.1) and the port is 8080. Some browsers may have to be configured to use the device's proxy settings.

For Windows 10, right-click the Windows start-icon and select **Network Connections**. Select **Proxy** and configure the proxy settings.

For Windows Vista/7/8, open **Internet Properties**. Go to **Connections > LAN Settings** and enable and configure the **Proxy Server**.

For Mac OS X, open **System Preferences > Network > Wi-Fi > Advanced > Proxies**. Select **Web Proxy (HTTP)** and configure the proxy settings.

For iOS, go to **Settings > Wi-Fi**. Edit the wireless network. Scroll down to **HTTP PROXY**, select **Manual**, and configure the proxy settings.

For Android, in WiFi network connection settings, edit the wireless network. Select **Show advanced options**, configure a **Manual** proxy, and enter the proxy settings.

Force HTTP and HTTPS traffic to use the web proxy

Block HTTP and HTTPS access to the Internet from the wireless network so that the only path to the Internet is through the explicit proxy. You can edit or delete policies that allow HTTP or HTTPS access. You can also add a policy to the top of the list that **Denies** HTTP and HTTPS traffic.

FSSO - Fortinet Single Sign-On

Fortinet Single Sign-On (FSSO), formerly known as FortiGate Server Authentication Extension (FSAE), is the authentication protocol by which users can transparently authenticate to FortiGate, FortiAuthenticator, and FortiCache devices. The FortiAuthenticator unit identifies users based on their authentication from a different system, and can be authenticated via numerous methods:

- Users can authenticate through a web portal and a set of embeddable widgets.
- Users with FortiClient Endpoint Security installed can be automatically authenticated through the FortiClient SSO Mobility Agent.
- Users authenticating against Active Directory can be automatically authenticated.
- RADIUS Accounting packets can be used to trigger an FSSO authentication.
- Users can be identified through the FortiAuthenticator API. This is useful for integration with third-party systems.

Below are the TCP/UDP ports used by the multiple FSSO modes:

Purpose	Protocol/Port
LDAP group membership lookup (Global Catalog)	TCP/3268
LDAP domain controller discovery and group membership lookup	TCP/389
DC Agent keepalive and push logon info to CA	UDP/8002
CA keepalive and push logon info to FortiGate	TCP/8000
NTLM	TCP/8000
CA DNS	UDP/53
Workstation check, polling mode (preferred method)	TCP/445
Workstation check, polling mode (fallback method)	TCP/135, TCP/139, UDP/137
Remote access to logon events	TCP/445
Group lookup using LDAP	TCP/389
Group lookup using LDAP with global catalog	TCP/3268
Group lookup using LDAPS	TCP/636
Resolve FSSO server name	UDP/53

Configuring the FortiAuthenticator

The FortiAuthenticator unit can be integrated with external network authentication systems, such as RADIUS, LDAP, Windows AD, and FortiClients to poll user logon information and send it to the FortiGate unit.

To configure FortiAuthenticator polling:

1. Go to **Fortinet SSO Methods > SSO > General**.
2. In the **FortiGate** section, leave **Listening port** set to **8000**, unless your network requires you to change this. The FortiGate unit must allow traffic on this port to pass through the firewall. Optionally, you can set the **Login expiry** time (default is **480** minutes, or eight hours). This is the length of time users can remain logged in before the system logs them off automatically.
3. Select **Enable authentication** and enter the **Secret key**. Be sure to use the same secret key when configuring the FSSO Agent on FortiGate units.
4. In the **Fortinet Single Sign-On (FSSO)** section, enter the following information:

Enable Windows event log polling (e.g. domain controllers/Exchange servers)	Select for integration with Windows Active Directory
Enable RADIUS Accounting SSO clients	Select if you want to use a Remote RADIUS server.
Enable Syslog SSO	Select for integration with Syslog server.
Enable FortiClient SSO Mobility Agent Service	<p>Once enabled, also select Enable authentication to enable SSO by clients running FortiClient Endpoint Security.</p> <p>Enter the Secret key. Be sure to use the same secret key in the FortiClient Single Sign-On Mobility Agent settings.</p>

5. Select **OK**.

For more detailed information for each available setting, see the [FortiAuthenticator Administration Guide](#).

Configuring the FortiGate

The FortiAuthenticator unit needs to be added to the FortiGate as an SSO agent that will provide user logon information.

To add a FortiAuthenticator unit as SSO agent:

1. Go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Under **SSO/Identity**, select **Fortinet Single-Sign-On Agent**.
3. Enter a **Name**, set **Primary FSSO Agent** either to the IP address of the FortiAuthenticator unit or a name, and enter a **Password**.
4. Set **Collector Agent AD access mode** to either **Standard**, where you can specify **Users/Groups**, or **Advanced**, where you can specify an **LDAP Server**.
5. Select **OK**.

The FortiGate unit receives a list of user groups from the FortiAuthenticator unit or LDAP server. When you open the server, you can see the list of groups. You can use the groups in identity-based security policies.

FSSO user groups

You can only use FortiAuthenticator SSO user groups directly in identity-based security policies. You must create an FSSO user group, then add FortiAuthenticator SSO user groups to it. These FortiGate FSSO user groups will then become available for selection in identity-based security policies.

To create an FSSO user group:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. Set **Type** to **Fortinet Single Sign-On (FSSO)**.
4. Add **Members**. The groups available to add as members are SSO groups provided by SSO agents.
5. Select **OK**.

Configuring the FortiClient SSO Mobility Agent

In order for the user to successfully set up the SSO Mobility Agent in FortiClient, they must know the FortiAuthenticator IP address and pre-shared key/secret.

To configure FortiClient SSO Mobility Agent:

1. In FortiClient, go to **File > Settings**.
2. Under **Advanced**, select **Enable Single Sign-On mobility agent**.
3. In **Server address**, enter the IP address of the FortiAuthenticator.
4. In **Customize port**, enter the listening port number specified on the FortiAuthenticator unit. You can omit the port number if it is **8005**.
5. Enter the **Pre-shared key**.
6. Select **OK**.

For more detailed FSSO configurations, including with Windows AD, Citrix, Novell eDirectory, and more, see the [Authentication](#) guide.

CLI Syntax

The following section contains commands to control FSSO.

user fsso

The following command will set the server address, port, and password for multiple FSSO agents.

```
config user fsso
  edit <name_str>
    set name <string>
    set [server | server2 | server3 | server4 | server5] <string>
    set [port | port2 | port3 | port4 | port5] <integer>
    set [password | password2 | password3 | password4 | password5] <password>
  end
```

user fsso-polling

The following command will set the Active Directory server port.

```
config user fsso-polling
```

```
edit <name_str>
    set port <integer>
end
```

OFTP - Optimized Fabric Transfer Protocol

The Optimized Fabric Transfer Protocol (OFTP) is used when information is synchronized between FortiAnalyzer and FortiGate. Remote logging and archiving can be configured on the FortiGate to send logs to a FortiAnalyzer (and/or FortiManager) unit.

OFTP listens on ports TCP/514 and UDP/514.

You can connect to a FortiAnalyzer unit from a FortiGate unit using Automatic Discovery, so long as both units are on the same network. Connecting these devices in this way does not use OFTP. Instead, the Fortinet Discovery Protocol (FDP) is used to locate the FortiAnalyzer unit.

When you select Automatic Discovery, the FortiGate unit uses HELLO packets to locate any FortiAnalyzer units that are available on the network within the same subnet. When the FortiGate unit discovers the FortiAnalyzer unit, the FortiGate unit automatically enables logging to the FortiAnalyzer unit and begins sending log data.

CLI command - To connect to FortiAnalyzer using automatic discovery:

```
config log fortianalyzer setting
  set status [enable | disable]
  set server <ip_address>
  set gui-display [enable | disable]
  set address-mode auto-discovery
end
```

If your FortiGate unit is in Transparent mode, the interface using the automatic discovery feature will not carry traffic.

To send logs from FortiGate to FortiAnalyzer:

1. Go to **Log & Report > Log Settings** and enable **Send logs to FortiAnalyzer/FortiManager** (under **Remote Logging and Archiving**).
2. Enter the FortiAnalyzer unit's IP address in the **IP address** field provided.
3. For **Upload option**, select either **Real Time** to upload logs as they come across the FortiGate unit, or **Every Minute**, or **Every 5 Minutes**.
4. Logs sent to FortiAnalyzer can be encrypted by enabling **SSL encrypt log transmission**.

FortiClient EMS - Enterprise Management Server

FortiClient Enterprise Management Server (FortiClient EMS) is a security management solution that enables scalable and centralized management of multiple endpoints (computers). FortiClient EMS provides efficient and effective administration of endpoints running FortiClient. It provides visibility across the network to securely share information and assign security profiles to endpoints. It is designed to maximize operational efficiency and includes automated capabilities for device management and troubleshooting.

FortiClient EMS is designed to meet the needs of small to large enterprises that deploy FortiClient on endpoints. Benefits of deploying FortiClient EMS include:

- Remotely deploying FortiClient software to Windows PCs.
- Updating profiles for endpoint users regardless of access location, such as administering antivirus, web filtering, VPN, and signature updates.
- Administering FortiClient endpoint registrations, such as accepting, deregistering, and blocking registrations.
- Managing endpoints, such as status, system, and signature information.
- Identifying outdated versions of FortiClient software.

Required services

You must ensure that required ports and services are enabled for use by FortiClient EMS and its associated applications on your server. The required ports and services enable FortiClient EMS to communicate with clients and servers running associated applications.

Communication	Service	Protocol	Port
FortiClient endpoint registration	File transfers	TCP	8013 (default)
Computer browser service	Enabled		
Samba (SMB) service <ul style="list-style-type: none">• During FortiClient deployment, endpoints may connect to the FortiClient EMS server using the SMB service.	Enabled		445
Distributed Computing Environment / Remote Procedure Calls (DCE- RPC) <ul style="list-style-type: none">• The FortiClient EMS server connects to the endpoints using RPC for FortiClient deployment.	Enabled		135
Active Directory server connection	When used as a default connection		389
Windows	HTTP	TCP	80

Communication	Service	Protocol	Port
Internet Information Services (IIS)	HTTPS	TCP	443, 10443
SQL server			

For more informationn about FortiClient EMS, including other requirements, installation, and management, see the [FortiClient EMS - Administration Guide](#).

Chapter 9 - FortiWiFi and FortiAP Configuration Guide

This FortiOS Handbook chapter contains the following sections:

[Introduction to wireless networking](#) explains the basic concepts of wireless networking and how to plan your wireless network.

[Configuring a WiFi LAN](#) explains how to set up a basic wireless network, prior to deploying access point hardware.

[Access point deployment](#) explains how to deploy access point hardware and add it to your wireless network configuration.

[Wireless mesh](#) explains how to configure a Wi-Fi network where access points are connected to the Wi-Fi controller wirelessly instead of by Ethernet.

[Combining WiFi and wired networks with a software switch](#) shows how to use the FortiAP Wi-Fi-Ethernet bridge feature.

[Protecting the WiFi network](#) explains the Wireless Intrusion Detection System (WIDS).

[Wireless network monitoring](#) explains how to monitor your wireless clients and how to monitor other wireless access points, potentially rogues, in your coverage area.

[Configuring wireless network clients](#) explains how to configure typical wireless clients to work with a WPA-Enterprise protected network.

[Wireless network examples](#) provides two examples. The first is a simple Wi-Fi network using automatic configuration. The second is a more complex example of a business with two Wi-Fi networks, one for employees and another for guests or customers.

[Using a FortiWiFi unit as a client](#) explains how to use a FortiWiFi unit as a wireless client to connect to other Wi-Fi networks. This connection can take the place of an Ethernet connection where wired access to a network or to the Internet is not available.

[Support for location-based services](#) explains how Fortinet supports location-based services that collect information about devices near FortiGate-managed access points, even if the devices don't associate with the network.

[Reference](#) provides information about Wi-Fi radio channels.

What's new in FortiOS 6.0.1

The following new wireless features added in FortiOS 6.0.1. Click on a link to navigate to that section for further information.

- ["Locate a FortiAP with LED blinking" on page 1138](#)

What's new in FortiOS 6.0

Introduction to wireless networking

This chapter introduces some concepts you should understand before working with wireless networks, describes Fortinet's wireless equipment, and then describes the factors you need to consider in planning deployment of a wireless network.

Wireless concepts

Wireless networking is radio technology, subject to the same characteristics and limitations as the familiar audio and video radio communications. Various techniques are used to modulate the radio signal with a data stream.

Bands and channels

Depending on the wireless protocol selected, you have specific channels available to you, depending on what region of the world you are in.

- IEEE 802.11b and g protocols provide up to 14 channels in the 2.400-2.500 GHz Industrial, Scientific and Medical (ISM) band.
- IEEE 802.11a,n (5.150-5.250, 5.250-5.350, 5.725–5.875 GHz, up to 16 channels) in portions of Unlicensed National Information Infrastructure (U-NII) band

Note that the width of these channels exceeds the spacing between the channels. This means that there is some overlap, creating the possibility of interference from adjacent channels, although less severe than interference on the same channel. Truly non-overlapping operation requires the use of every fourth or fifth channel, for example ISM channels 1, 6 and 11.

The capabilities of your wireless clients is the deciding factor in your choice of wireless protocol. If your clients support it, 5GHz protocols have some advantages. The 5GHz band is less used than 2.4GHz and its shorter wavelengths have a shorter range and penetrate obstacles less. All of these factors mean less interference from other access points, including your own.

When configuring your WAP, be sure to correctly select the Geography setting to ensure that you have access only to the channels permitted for WiFi use in your part of the world.

For detailed information about the channel assignments for wireless networks for each supported wireless protocol, see [Reference on page 1212](#).

Power

Wireless LANs operate on frequencies that require no license but are limited by regulations to low power. As with other unlicensed radio operations, the regulations provide no protection against interference from other users who are in compliance with the regulations.

Power is often quoted in dBm. This is the power level in decibels compared to one milliwatt. 0dBm is one milliwatt, 10dBm is 10 milliwatts, 27dBm, the maximum power on Fortinet FortiAP equipment, is 500 milliwatts. The FortiGate unit limits the actual power available to the maximum permitted in your region as selected by the WiFi controller country setting.

Received signal strength is almost always quoted in dBm because the received power is very small. The numbers are negative because they are less than the one milliwatt reference. A received signal strength of -60dBm is one millionth of a milliwatt or one nanowatt.

Antennas

Transmitted signal strength is a function of transmitter power and antenna gain. Directional antennas concentrate the signal in one direction, providing a stronger signal in that direction than would an omnidirectional antenna.

FortiWiFi units have detachable antennas. However, these units receive regulatory approvals based on the supplied antenna. Changing the antenna might cause your unit to violate radio regulations.

Security

There are several security issues to consider when setting up a wireless network.

Whether to broadcast SSID

It is highly recommended to broadcast the SSID. This makes connection to a wireless network easier because most wireless client applications present the user with a list of network SSIDs currently being received. This is desirable for a public network.

Attempting to obscure the presence of a wireless network by not broadcasting the SSID does not improve network security. The network is still detectable with wireless network “sniffer” software. Clients search for SSIDs that they know, leaking the SSID. Refer to [RFC 3370](#). Also, many of the latest Broadcom drivers do not support hidden SSID for WPA2.

Encryption

Wireless networking supports the following security modes for protecting wireless communication, listed in order of increasing security.

None — Open system. Any wireless user can connect to the wireless network.

WEP64 — 64-bit Web Equivalent Privacy (WEP). This encryption requires a key containing 10 hexadecimal digits.

WEP128 — 128-bit WEP. This encryption requires a key containing 26 hexadecimal digits.

WPA — 256-bit WiFi Protected Access (WPA) security. This encryption can use either the TKIP or AES encryption algorithm and requires a key of either 64 hexadecimal digits or a text phrase of 8 to 63 characters. It is also possible to use a RADIUS server to store a separate key for each user.

WPA2 — WPA with security improvements fully meeting the requirements of the IEEE 802.11i standard. Configuration requirements are the same as for WPA.

For best security, use the WPA2 with AES encryption and a RADIUS server to verify individual credentials for each user. WEP, while better than no security at all, is an older algorithm that is easily compromised. With either WEP or WAP, changing encryption passphrases on a regular basis further enhances security.

Separate access for employees and guests

Wireless access for guests or customers should be separate from wireless access for your employees. Each of the two networks can have its own SSID, security settings, firewall policies, and user authentication. This does not

require additional hardware. Both FortiWiFi units and FortiAP units support multiple wireless LANs on the same access point.

A good practice is to broadcast the SSID for the guest network to make it easily visible to users, but not to broadcast the SSID for the employee network.

Two separate wireless networks are possible because multiple virtual APs can be associated with an AP profile. The same physical APs can provide two or more virtual WLANs.

Captive portal

As part of authenticating your users, you might want them to view a web page containing your acceptable use policy or other information. This is called a captive portal. No matter what URL the user initially requested, the portal page is returned. Only after authenticating and agreeing to usage terms can the user access other web resources.

For more information about captive portals, see the Captive portals chapter of the FortiOS Authentication Guide.

Power

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. There are people who look for wireless networks and attempt to access them. If your office WLAN is receivable out on the public street, you have created an opportunity for this sort of activity.

Monitoring for rogue APs

It is likely that there are APs available in your location that are not part of your network. Most of these APs belong to neighboring businesses or homes. They may cause some interference, but they are not a security threat. There is a risk that people in your organization could connect unsecured WiFi-equipped devices to your wired network, inadvertently providing access to unauthorized parties. The optional On-Wire Rogue AP Detection Technique compares MAC addresses in the traffic of suspected rogues with the MAC addresses on your network. If wireless traffic to non-Fortinet APs is also seen on the wired network, the AP is a rogue, not an unrelated AP.
